The condensed Lean proof of RH and GRH: a reading

First handout, working draft of November 26, 2026

What this is, and what it is not. The Lean repository `lsernau/grh-lean` states the Riemann hypothesis and the generalized Riemann hypothesis for Dirichlet L-functions in Mathlib's terms and proves them. Its authors report that Lean's kernel accepts the proofs with the three standard axioms only. That is a *claim* about a formal text: no mathematician has read the argument through, and no paper accompanies it. This handout is a reading of the compact edition at the commit above, from the final theorems down, in the order of the argument: each unit of the formal text is rewritten as mathematics from structured proofs that a program compared with the Lean source line by line. Classical results that the formal text proves in its background library are quoted from the literature instead of read. Nothing here says that RH is proved.

State of the reading. The argument is divided into 24 units in eight chapters (2 621 declarations). Units read (note built, structured proofs checked): 24. Structured proofs checked by program, note in preparation: 0. Dossier written, not yet passing its check: 0. Being read: 0. Entries of the catalogue of quoted results so far: 2 944.

Readers: Claude agents (dossiers and structured proofs, checked by `rb.py check`). Writer: Claude (notes). Second reader: an independent AI reader. Method: Readback. Every count in this handout is computed from the workspace at build time.

Overview of the argument

1. What is claimed

The formal text ends with five theorems. Let ζ be the Riemann zeta function, $M \geq 1$ an integer, χ a Dirichlet character modulo M, primitive or not, and $L(s, \chi)$ its L-function. The five theorems say:

(1) every $s \in \mathbb{C}$ with $\zeta(s) = 0$, $s \notin \{-2, -4, -6, \dots\}$ and $s \neq 1$ has $\operatorname{Re} s = \frac{1}{2}$; this is the proposition that Mathlib defines as the Riemann hypothesis;

(2) the same statement, written out in the statement file of the repository; its formal proof is theorem (1) itself, so the two propositions agree by definition;

(3) $L(s, \chi) \neq 0$ whenever $\operatorname{Re} s > \frac{1}{2}$, unless χ is principal and $s = 1$;

(4) every zero s of $L(\,\cdot\,, \chi)$ with $0 < \operatorname{Re} s < 1$ has $\operatorname{Re} s = \frac{1}{2}$;

(5) statement (4) for primitive χ. It is a special case of (4): its proof does not use primitivity.

In Mathlib ζ and $L(\,\cdot\,, \chi)$ are functions on all of $\mathbb{C}$: the meromorphic continuations, with a conventional finite value at the pole $s = 1$ of ζ and of $L(\,\cdot\,, \chi)$ for principal χ. This is why $s = 1$ is excluded by hand. A Dirichlet character modulo M is a multiplicative map $\mathbb{Z}/M \to \mathbb{C}$ that vanishes off the units, and the principal character is 1 on the units. An imprimitive character lacks finitely many Euler factors of the primitive one, which adds zeros on the line $\operatorname{Re} s = 0$ only; hence the open strip in (4), and (3)–(5) say nothing about $\operatorname{Re} s \leq 0$.

What one must trust. Three things, and no more: the statement file, which imports only Mathlib and defines the propositions (2)–(5); Mathlib's definitions of ζ, of Dirichlet characters and of $L(s, \chi)$, at the pinned version; and Lean's kernel with its three standard axioms (propositional extensionality, choice, soundness of quotients). Every other definition of the repository, and so every object of this overview, occurs only inside proofs.

Status. The authors report that all files compile with no proof omitted and that the kernel accepts the five theorems from these axioms; the record of checks at the end of this handout says who checked what, including how far our own replay has got. That is a fact about a formal text. No mathematician has read the argument through, and no paper accompanies it. The result is therefore a *claim*: this handout describes what the formal proof asserts and how it argues, and it does not say that the Riemann hypothesis is proved. The repository attributes the proof to Levent Alpöge, with Claude, and says that its Lean text was written by Claude; the compact edition read here rewrites an earlier, longer formal proof and follows its method.

Three grades of statement. *Kernel-checked, as reported*: every statement of the formal text, so every theorem in a box below. *Read*: rewritten by us as mathematics from structured proofs that a program compared with the source; the chapter list after this overview shows the state of each unit. *Quoted*: results that the formal text proves in its background library and that we state without reading their proofs: classical results, cited from the literature, and one result that the literature covers only in part (Section 6). In this overview every theorem in a box was compared, hypothesis by hypothesis, with its Lean statement, and the closing table gives the places; the objects of Setting 2 are described after their Lean definitions and the authors' comments, and the chapters define them. The deductions carried out in Sections 2 to 4 follow short Lean proofs that were read in the source. The paragraphs headed *Idea* are not readings of proofs: they report

the authors' comments and the statements of intermediate lemmas, and the chapters will replace them. The argument runs as follows; A, B, C are the three main theorems:

$$\text{A, B, C} \overset{\S4}{\Longrightarrow} \text{main inequality} \overset{\S3}{\Longrightarrow} \text{one-sided bound for primes} \overset{\S2}{\Longrightarrow} (3) \overset{\S2}{\Longrightarrow} (1)\text{–}(5).$$

2. From primes to zeros

The weighted prime sum. Let d be a prime and $M \geq 1$ an integer. Put $K = \mathbb{Q}(\sqrt{-d})$, and let χ_K be the quadratic character of the field $\mathbb{Z}/d$, a Dirichlet character modulo d (the Legendre symbol $(\,\cdot\,/d)$ when d is odd); for $d \equiv 3 \bmod 4$ it is the quadratic character of K. With Λ the von Mangoldt function, define for integers $\nu \geq 1$

$$\lambda_{d,M}(\nu) = \Lambda(\nu)\big(1 - \chi_K(\nu)\big) \ \text{ if } \nu \equiv 1 \bmod M, \qquad \lambda_{d,M}(\nu) = 0 \ \text{ otherwise.}$$

So $\lambda_{d,M} \geq 0$, and, when $d \equiv 3 \bmod 4$ (as for every d used below, all $\equiv 7 \bmod 8$), $\lambda_{d,M}$ vanishes at the powers of the primes that split in K. For real x the *remainder* is

$$R_{d,M}(x) = \sum_{1 \leq \nu \leq x} \lambda_{d,M}(\nu)\Big(\frac{1}{\nu} - \frac{1}{x}\Big) - \frac{\log x}{\varphi(M)} - \kappa_{d,M},$$
$$\kappa_{d,M} = \frac{1}{\varphi(M)} \operatorname{Re}\Big(\sum_{\xi}\Big(\frac{\tilde{L}'}{\tilde{L}}(1, \xi\chi_K) - \frac{\tilde{L}'}{\tilde{L}}(1,\xi)\Big) - 1\Big).$$

Here φ is Euler's function, ξ runs over the Dirichlet characters modulo M, $\xi\chi_K$ is the character modulo Md with the values $\xi(\nu)\chi_K(\nu)$, and $\tilde{L}(s,\xi)$ is the entire function $L(s,\xi)$, or $(s-1)L(s,\xi)$ if ξ is principal. The term $\log x/\varphi(M) + \kappa_{d,M}$ is the expected value of the sum. (A remark of ours: by the explicit formula, the generalized Riemann hypothesis gives $R_{d,M}(x) = O(x^{-1/2})$.)

Zeros as poles. Let the prime d be $\equiv 7 \bmod 8$ and prime to M. The Laplace transform $\Phi_{d,M}(s) = \int_0^\infty R_{d,M}(e^v)\, e^{(1-s)v}\, dv$, defined for $\operatorname{Re} s > 2$, continues to a meromorphic function on $\mathbb{C}$ that is analytic at every point of the closed half-plane $\operatorname{Re} s \geq 1$, the point $s = 1$ included: the constant $\kappa_{d,M}$ is the one that cancels the pole at $s = 1$. In $\operatorname{Re} s > 0$ its poles are at most simple, and for $\operatorname{Re}\rho > 0$, $\rho \neq 1$, the product $(s-\rho)\Phi_{d,M}(s)$ tends, as $s \to \rho$, to

$$\operatorname{res}_{d,M}(\rho) = \frac{1}{\varphi(M)\,\rho(1-\rho)} \sum_{\xi}\Big(\operatorname{ord}_\rho \tilde{L}(\,\cdot\,,\xi) - \operatorname{ord}_\rho \tilde{L}(\,\cdot\,,\xi\chi_K)\Big),$$

where $\operatorname{ord}_\rho f$ is the order of vanishing at ρ of an entire function $f \neq 0$; one puts $\operatorname{res}_{d,M}(1) = 0$, the limit at $\rho = 1$. A zero of some $L(\,\cdot\,,\xi)$, ξ modulo M, counts positively, and a zero of a twist $L(\,\cdot\,,\xi\chi_K)$ negatively.

One-sided criterion. Let $M \geq 1$ be an integer, c a unit of $\mathbb{Z}/M$ and $\beta > \frac{1}{2}$ a real number. Suppose that every prime $d \equiv c \bmod M$ satisfies $d \equiv 7 \bmod 8$, is prime to M, and has

$$R_{d,M}(x) \leq x^{\beta-1} \quad \text{for all sufficiently large real } x.$$

Then $\tilde{L}(\rho,\chi) \neq 0$ for every Dirichlet character χ modulo M and every $\rho \in \mathbb{C}$ with $\operatorname{Re}\rho > \beta$.

The proof has two inputs from the background library; one may assume $\operatorname{Re}\rho < 1$, the rest being classical. Given ρ, the first input provides one prime $d \equiv c \bmod M$ for which no $\tilde{L}(s,\xi\chi_K)$, ξ modulo M, vanishes in the box $\operatorname{Re} s \geq \beta$, $|\operatorname{Im} s| \leq |\operatorname{Im}\rho|$; it rests on estimates

of zero-density type for quadratic twists, and Section 6 says what of it the literature covers. This is why the bound is asked of every prime of the class: the prime depends on the height of ρ. For this d the numbers $\operatorname{res}_{d,M}(s)$ at real points $s > \beta$ are non-negative, and a constant multiple of $e^{(\beta-1)v}$ exceeds $R_{d,M}(e^v)$ for all $v \geq 0$. Now Landau's theorem applies: the Laplace transform of a non-negative function has a singularity at the real point of its abscissa of convergence. This is the integral form of his theorem on Dirichlet series with non-negative coefficients, used in a version that tolerates real poles of the favourable sign. So $\Phi_{d,M}$ has no pole in $\operatorname{Re} s > \beta$, and $\operatorname{res}_{d,M}(\rho) = 0$. At ρ the twisted terms vanish by the choice of d; the remaining terms are non-negative with sum zero, so each is zero.

One-sided bound. Let N_0 be a positive multiple of 18480, let d be a prime with $d \equiv N_0/2 - 1 \bmod N_0$, and let ε be real with $0 < \varepsilon < \frac{1}{100}$. Then

$$R_{d,N_0}(x) \leq x^{8\varepsilon - 1/2} \quad \text{for all sufficiently large real } x.$$

How the five theorems follow. Let χ be a character modulo M and suppose $L(\rho, \chi) = 0$ with $\operatorname{Re}\rho > \frac{1}{2}$, the pole excepted. Put $N_0 = 18480\,M$ and $c = N_0/2 - 1$. Then $c^2 \equiv 1 \bmod N_0$, so c is a unit, and every prime $d \equiv c \bmod N_0$ is prime to N_0 and is $\equiv 7 \bmod 8$, because 16 divides $18480 = 2^4 \cdot 3 \cdot 5 \cdot 7 \cdot 11$. The character modulo N_0 induced by χ still has $\tilde{L}(\rho, \cdot) = 0$, the two L-functions differing by Euler factors without zeros in $\operatorname{Re} s > 0$. Choose $\varepsilon = (\min(\operatorname{Re}\rho, 1) - \frac{1}{2})/51$, so that $\varepsilon < \frac{1}{100}$ and $\beta = 8\varepsilon + \frac{1}{2} < \operatorname{Re}\rho$. The one-sided bound, for every such d, is the hypothesis of the criterion with modulus N_0, and the criterion contradicts the zero. This is theorem (3). The functional equation, taken from Mathlib for primitive characters and extended to all characters through their missing Euler factors, pairs a zero s in the strip with the zero $1 - s$ of $L(\cdot, \bar{\chi})$, which gives (4) and (5); for $M = 1$, with the trivial zeros and the pole treated by the functional equation of ζ, it gives (1) and (2). Everything else in the formal text serves the one-sided bound.

3. The main inequality

Setting 1 (parameters and data). *Parameters* are a pair $P = (N_0, d)$: a positive multiple N_0 of 18480 and a prime $d \equiv N_0/2 - 1 \bmod N_0$. Then $d \equiv 7 \bmod 8$, and every prime dividing N_0 splits in $K = \mathbb{Q}(\sqrt{-d})$. *Admissible data* for P are a record D with these components: real scales x, x_1, b (stored by their logarithms); natural numbers μ, m, r: m a power of 2 with $\sqrt{x} \leq m \leq 2\sqrt{x}$, the exponent μ with $2^\mu = m^{22}$ and $\mu \leq 32 \log x$, and r a power of 3 with $x^5 \leq r \leq 3x^5$; a finite set $\operatorname{thick}(D)$ of infinite places of the field $E(D)$ defined below; two distinct primes g_0, g_1 and an integer π_g of K with $\pi_g \bar{\pi}_g = g_0 g_1$. The scales satisfy

$$(\log b)^{100} \leq x, \qquad x^{10^6} \leq x_1, \qquad x_1^{10^6} \leq b, \qquad (\log x_1)^6 \leq \log b,$$

and there are further conditions, stated in Chapter III: a lower bound for $\log\log b$ by a constant of P, congruences and sizes for g_0, g_1 (both between b^{10} and b^{11}), conditions on $\operatorname{thick}(D)$, and the existence of primes in certain short windows.

So $\log b \ll x \ll x_1 \ll b$, with large gaps, and $m \approx \sqrt{x}$ is the number of theta lifts: the saving $x^{-1/2}$ of the one-sided bound will be $1/m$. The following objects are functions of D.

The field and its places. $N_1(D)$ is $N_0\,2^\mu = N_0\,m^{22}$ times a power of 3 fixed by μ, and $E(D)$ is K with the roots of unity of order $N_1(D)$ adjoined: a CM field, abelian over $\mathbb{Q}$. Its infinite places form a principal homogeneous space under $\operatorname{Gal}(E(D)/K)$. Restriction to the roots of unity identifies this group with $(\mathbb{Z}/N_1(D))^\times$: it is onto because K is not contained in the field that these roots of unity generate over $\mathbb{Q}$, the prime d being ramified in K and prime to $N_1(D)$. A base place identifies the places with this group. So a place τ has a class

modulo $N_1(D)$, and $\nu \cdot \tau$ is defined for integers ν prime to $N_1(D)$. The set $\mathrm{tops}(D)$ consists of the places of class $\equiv 1 \bmod N_0$; it has $N_1(D)/N_0$ elements, and $f(D) = \varphi(N_0) \cdot \#\mathrm{tops}(D)$ is the number of all infinite places. The places of $\mathrm{thick}(D)$ have class $\equiv -1 \bmod N_0$.

Sizes. $k(D) = r + 1 - m$ and $t(D) = 5r$; $a(D)$ is the least multiple of $N_1(D)$ that is at least $x\,b$; and $\mathrm{budget}(D) = f(D)\,a(D)\,(\log b)^3$.

Prime sums. The *nominal weight* of an infinite place τ is $w_D(\tau) = a(D)/x$ if $\tau \in \mathrm{thick}(D)$ and $w_D(\tau) = a(D)/x_1$ otherwise. For real z and an infinite place τ, with $(\,\cdot\,)_+$ the positive part, put

$$\mathrm{Ask}_D(z,\tau) = \sum_{\nu=1}^{a(D)} \lambda_{d,1}(\nu)\Big(\frac{z}{\nu} - w_D((-\nu)\cdot\tau)\Big)_+,$$

$$\mathrm{rem}(D) = \sum_{\tau \in \mathrm{tops}(D)} \Big(\mathrm{Ask}_D(a(D),\tau) - a(D)\big(\log a(D) + \kappa_{d,1} - \bar{w}_D\big)\Big).$$

Here $(-\nu)\cdot\tau$ is the image of τ under the class of $-\nu$ modulo $N_1(D)$ when ν is prime to $N_1(D)$, and τ itself otherwise; the terms with ν not prime to $N_1(D)$ vanish in any case, since every prime dividing $N_1(D)$ splits in K (Setting 1), so that $\Lambda(\nu) = 0$ or $1 - \chi_K(\nu) = 0$. Further, $\bar{w}_D$ is the mean of $\log w_D(\tau)$ over all infinite places τ of $E(D)$. (The formal text writes $\kappa_{d,1}$ as -1 minus Euler's constant plus $\mathrm{Re}(L'/L)(1,\chi_K)$; a lemma of Chapter II identifies the two.) In Section 4 the number $\mathrm{Ask}_D(z,\tau)$ will be the divisibility that the primes not split in K give to a derivative of order z at τ, and $\mathrm{rem}(D)$ is what the tops receive beyond the expected value. Finally the *main amount* is $h_{\mathrm{main}}(D) = m\,k(D)\,\mathsf{U}(D)$, where $\mathsf{U}(D)$, the *cost of one direction*, is a sum over all infinite places τ: the size charged to a derivative of order about $w_D(\tau)$, a factorial against a power of a period, less the divisibility $\mathrm{Ask}_D(w_D(\tau),\tau)$ that such a derivative is sure to have. Chapter III has the formula. Its value plays no role here: it cancels.

The remainder is a combination of the remainders of Section 2. As τ runs over $\mathrm{tops}(D)$, the place $(-\nu)\cdot\tau$ meets every thick place exactly once if $\nu \equiv 1 \bmod N_0$, and none otherwise. This is where the progression $1 \bmod N_0$ enters, and it gives the identity

$$\mathrm{rem}(D) = a(D)\Big(\#\mathrm{thick}(D)\,\big(R_{d,N_0}(x) - R_{d,N_0}(x_1)\big) + \#\mathrm{tops}(D)\,R_{d,1}(x_1)\Big). \tag{1}$$

Main inequality. In Setting 1, for all parameters P and all admissible data D for P, with number of lifts m and third scale b,

$$m \cdot \mathrm{rem}(D) \;\le\; (\log b)^2 \cdot \mathrm{budget}(D) \;=\; f(D)\,a(D)\,(\log b)^5.$$

From the main inequality to the one-sided bound. Fix ε and let x be large. Data exist with first scale x, with $\log b = x^{\varepsilon}$, $\log x_1 = x^{\varepsilon/6}$, and with $\#\mathrm{thick}(D) \ge \#\mathrm{tops}(D)/\log b$ (Chapter III; the thick set is a construction of Behrend type). Solving (1) for $R_{d,N_0}(x)$ leaves the combination $R_{d,N_0}(x_1) - X\,R_{d,1}(x_1)$ with $X = \#\mathrm{tops}(D)/\#\mathrm{thick}(D) \le \log b$. No pointwise prime number theorem in progressions is used to bound it. Instead, since both remainders have transforms without poles on $\mathrm{Re}\,s \ge 1$, every long window contains a good point: for $v_0 = 10^6 \log x$ large and every $X \in [0, e^{v_0}]$ there is $v_1 \in [v_0, v_0^2]$ with $R_{d,N_0}(e^{v_1}) - X\,R_{d,1}(e^{v_1}) \le e^{-v_0}$. Replacing x_1 by e^{v_1} keeps the data admissible. For the new data D' the main inequality and (1) give

$$R_{d,N_0}(x) \;\le\; \frac{f(D')\,(\log b)^5}{m \cdot \#\mathrm{thick}(D')} + x^{-10^6} \;\le\; \frac{\varphi(N_0)\,(\log b)^6}{\sqrt{x}} + x^{-10^6} \;\le\; x^{8\varepsilon - 1/2}.$$

4. Theorems A, B and C

One covolume is bounded from both sides. Theorems A and B produce many automorphic forms whose theta lifts are short and almost integral; Theorem C says that integral forms cannot be that short. The two bounds differ by $m \cdot \mathrm{rem}(D)$.

Setting 2 (forms and lifts). Let P and D be as in Setting 1. Chapters III, V and VII attach to D the following objects.

Levels. The number $g(D) = g_0 g_1$; a prime $N(D)$ that splits completely in $E(D)$, with $m \log b \le \log N(D) \le 30\, m \log b$; an integer $\pi_N(D)$ of $E(D)$ whose product with its complex conjugate is $N(D)$. The *chosen primes* are the primes of $E(D)$ that divide $\bar{\pi}_g$, and $\mathsf{G}(D)$ is the product of the groups GL_r of their residue fields, a finite group.

Columns. $\mathrm{Col}(D)$ is a finite-dimensional complex space of algebraic modular forms on the unitary group of a definite hermitian space of rank $k(D)$ over $E(D)$, of a fixed weight, with level at the chosen primes and at the primes dividing $\pi_N(D)$. Its subspace $\mathrm{Col}^{\mathrm{ram}}(D)$ of *ramified* columns is the image of the product, over the primes $\mathfrak{p}$ dividing $\pi_N(D)$, of the operators $1-$(translation by a central element at $\mathfrak{p}$). For a prime ℓ and a ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_\ell$, let O_j be the ring of the complex numbers whose image under j has absolute value at most 1. The values of these forms are vectors of a weight representation, and integrality is measured in a lattice that moves with the point: a form is *j-integral* if at every finite adelic point its value lies in the weight lattice at that point, that is, after j is applied to its coordinates and then the local weight action of the inverse of the point, all coordinates have absolute value at most 1. A column is *integral* if it is j-integral for every prime ℓ and every j.

Rows. $\mathrm{Row}(D)$ is a finite-dimensional complex space of cusp forms on the unitary group of an indefinite hermitian space of rank r over $E(D)$: of a fixed discrete series type at infinity, of principal level at the chosen primes and with no level at $N(D)$, cut out by a fixed idempotent of the group algebra of $\mathsf{G}(D)$.

Poincaré series. For $\gamma \in \mathsf{G}(D)$, the linear map $\mathcal{P}_D(\gamma)\colon \mathrm{Col}^{\mathrm{ram}}(D) \to \mathrm{Row}(D)$ multiplies a ramified column by a fixed non-zero constant, forms its Poincaré series on the indefinite group, translates it by γ and applies $\#\mathsf{G}(D)$ times the idempotent.

Twists and lifts. An *m-fold twist* of D is a continuous character ϑ of the norm-one adeles of $E(D)$, trivial on the norm-one elements of $E(D)$ and at the infinite places, at most tamely ramified, such that the set $Q(\vartheta)$ of primes where it ramifies contains the complex conjugate of none of its members, consists of primes of norm prime to $g(D)N(D)$, and is also the set of ramified primes of each of $\vartheta^2, \dots, \vartheta^m$. The trivial character 1 is one. For an m-fold twist ϑ, the map $\Theta_{D,\vartheta}\colon \mathrm{Row}(D) \to \mathcal{A}_{D,\vartheta}$ is the composite of m theta lifts, the i-th formed with ϑ^i; it is injective, and $\mathcal{A}_{D,\vartheta}$ is a space of algebraic modular forms on a definite unitary group of rank $r + m\, t(D)$. For $F, F' \in \mathcal{A}_{D,\vartheta}$ and $\sigma \in \mathrm{Aut}(\mathbb{C})$, $\langle F, F' \rangle_\sigma$ is the Petersson product, a finite sum over classes, of the forms whose values are the σ-conjugates of those of F and F'. Put $\|F\|_\sigma^2 = \langle F, F \rangle_\sigma$ and $\mathrm{covol}_\sigma^2(F_1, \dots, F_n) = |\det(\langle F_i, F_{i'} \rangle_\sigma)_{i,i'}|$. For forms in $\mathcal{A}_{D,\vartheta}$, j-integrality is defined as for columns, in the weight lattice at each point.

Index. Rows $y_1, \dots, y_n$ have *D-index at most δ* if there are real numbers η_ℓ, $\ell \in \mathbb{N}$, with $\sum_{\ell \in J} \eta_\ell \le \delta$ for every finite $J \subset \mathbb{N}$, such that for every prime ℓ, every $j\colon \mathbb{C} \to \mathbb{C}_\ell$ and every m-fold twist ϑ of D with ℓ prime to the norms of the primes in $Q(\vartheta)$ there is an $n \times n$ matrix u over O_j with $|j(\det u)|_\ell \ge e^{-\eta_\ell}$ for which $\Theta_{D,\vartheta}(\sum_{i'} u_{ii'}\, y_{i'})$ is j-integral for $i = 1, \dots, n$.

Theorem A (short forms). In Settings 1 and 2 there is a rational number $q > 0$ with the following two properties.

(a) Size. There is a set S of integral ramified columns that spans $\mathrm{Col}^{\mathrm{ram}}(D)$ over $\mathbb{C}$ such that, for all $\psi \in S$, all $\gamma \in \mathsf{G}(D)$ and all $\sigma \in \mathrm{Aut}(\mathbb{C})$,

$$\big\|\Theta_{D,1}(q\,\mathcal{P}_D(\gamma)\psi)\big\|_\sigma^2 \;\le\; \exp\big(h_{\mathrm{main}}(D) - m\cdot\mathrm{rem}(D) + \log b\cdot\mathrm{budget}(D)\big).$$

(b) Index. For every finite set $\mathcal{T} \subseteq \mathsf{G}(D)$, every $n \ge 0$ and all rows $y_1, \dots, y_n$, each of the form $q\,\mathcal{P}_D(\gamma)\psi$ with $\gamma \in \mathcal{T}$ and ψ an integral ramified column, the family $y_1, \dots, y_n$ has D-index at most $\#\mathcal{T}\cdot\dim\mathrm{Col}(D)\cdot\mathrm{budget}(D)$.

Idea (the authors' comments; Chapter V). A seesaw identity moves the problem to definite groups: for every twist, the chain of lifts of the Poincaré series of a ramified column is a chain of m theta lifts of the column itself between definite spaces, restricted at the end. There a lift is a finite sum of Taylor coefficients at the origin of theta functions with complex multiplication by K, of order $a(D)$ at the tops. Their size at every conjugate comes from Stirling's formula and a period. Their divisibility at a prime p not split in K comes from the formal group of the CM curve, of height two at p: a derivative of order z against a partner place of weight w gains about $(z/p - w)_+$ powers of p. Summed over p with weights $\log p$ this is Ask_D, which is why $\lambda_{d,M}$ appears. The rational q divides the gain out, a power of the prime $N(D)$, chosen in a short window, pays the excess of size over expected divisibility, and $h_{\mathrm{main}}(D) - m\cdot\mathrm{rem}(D)$ is left. What some primes lose is regained on the image of scaled Hecke operators, at the price of the D-index in (b).

Theorem B (enough forms). In Settings 1 and 2, $\dim\mathrm{Col}(D) > 0$ and $\dim\mathrm{Row}(D) > 0$, and there is a finite set $\mathcal{T} \subseteq \mathsf{G}(D)$ with

$$\#\mathcal{T}\cdot\dim\mathrm{Col}(D) \;\le\; 5\,\dim\mathrm{Row}(D)\cdot\log(1+b^2) \qquad \text{and}$$
$$\dim\sum_{\gamma\in\mathcal{T}}\mathcal{P}_D(\gamma)(\mathrm{Col}^{\mathrm{ram}}(D)) \;\ge\; \Big(1-\frac{4}{b^2}\Big)\dim\mathrm{Row}(D).$$

Idea (Chapter VI). The translates are spread: for every subspace W of $\mathrm{Row}(D)$ some γ pulls W back to at most the share $\frac{1}{2}(1 + \dim W/\dim\mathrm{Row}(D)) + b^{-2}$ of the columns. This follows from a second moment of the Poincaré series over $\mathsf{G}(D)$, of Petersson type: its main term is dominated, with constant one, by a positive kernel of Bessel integrals at the real places (the place $A = \mathbb{C}$ of Chapter VI, which the notes of that chapter call the complex place) and of local Bessel integrals at a large finite set of finite places, followed by a sieve; the chosen primes enter through the lines that the level group must fix. A variance inequality turns the moment into the bound. A greedy choice of translates then gains at each step in proportion to the dimension still missing, whence the logarithm.

Theorem C (integral forms are long). In Settings 1 and 2, let $n \ge 0$ be an integer, let $y_1, \dots, y_n$ be rows in $\mathrm{Row}(D)$ that are linearly independent over $\mathbb{C}$, and let δ and V be real numbers. Suppose that $n \ge (1 - 4/b^2)\dim\mathrm{Row}(D)$, that $y_1, \dots, y_n$ have D-index at most δ, and that $\mathrm{covol}_\sigma^2(\Theta_{D,1}y_1, \dots, \Theta_{D,1}y_n) \le e^V$ for all σ in $\mathrm{Aut}(\mathbb{C})$. Then

$$\dim\mathrm{Row}(D)\cdot\big(h_{\mathrm{main}}(D) - 3\log b\cdot\mathrm{budget}(D)\big) \;\le\; V + 2\delta.$$

Idea (Chapters IV, VII and VIII). The tool is a height for families $Z = (Z_{\ell,\iota})$ of complex numbers indexed by the pairs of a prime ℓ and a field isomorphism $\iota\colon \mathbb{C} \to \bar{\mathbb{Q}}_\ell$. Such a family

has *height at most* h if there are $H \in \mathbb{C}^\times$, $\alpha \in \mathbb{R}$ and real numbers η_ℓ with $|\sigma(H)| \le e^\alpha$ for all $\sigma \in \mathrm{Aut}(\mathbb{C})$, $|\iota(H\, Z_{\ell,\iota})|_\ell \le e^{\eta_\ell}$ for all (ℓ, ι), and such that α plus the sum of the η_ℓ over the primes ℓ below any sufficiently large bound is at most h. Heights add in products, and a height bound for the constant family 1 is non-negative: this is the product formula, applied to the norm of H. Let $\mathfrak{z}_D(\vartheta) = \det(\Theta^*_{D,\vartheta}\Theta_{D,\vartheta})$. For a fit family of twists θ (Section 5), two bounds hold. First, $\mathfrak{z}_D(\theta_{\ell,\iota})/\mathfrak{z}_D(1)$ has height at most $V + 2\delta + b \dim \mathrm{Row}(D)$: the family is completed to a basis by crude rows, V bounds the Gram determinant at the trivial twist at every conjugate, and the D-index bounds the denominators at each ℓ. Second, $\mathfrak{z}_D(1)^2/\mathfrak{z}_D(\theta_{\ell,\iota})^2$ has height at most $2 \dim \mathrm{Row}(D)\,(2 \log b \cdot \mathrm{budget}(D) - h_{\mathrm{main}}(D))$: the volume of the chain is a constant times the volumes of the m single lifts, a single lift is governed by Hecke L-values, and each ratio of an untwisted to a twisted value repays one direction, $\mathsf{U}(D)$. The square of the first family times the second is the constant family 1, so twice the first bound plus the second is non-negative. This is Theorem C, since $b \le \log b \cdot \mathrm{budget}(D)$.

A, B and C give the main inequality. Take q and S from A and $\mathcal{T}$ from B. The rows $q\,\mathcal{P}_D(\gamma)\psi$, $\gamma \in \mathcal{T}$, $\psi \in S$, span $\sum_{\gamma\in\mathcal{T}} \mathcal{P}_D(\gamma)(\mathrm{Col}^{\mathrm{ram}}(D))$; choose a basis $y_1, \dots, y_n$ of this space among them, so that $n \ge (1-4/b^2) \dim \mathrm{Row}(D)$. By Hadamard's inequality and A(a), $\mathrm{covol}^2_\sigma(\Theta_{D,1}y_1, \dots, \Theta_{D,1}y_n) \le e^V$ with $V = n\,(h_{\mathrm{main}}(D) - m\,\mathrm{rem}(D) + \log b \cdot \mathrm{budget}(D))$. By A(b) and B their D-index is at most $\delta = 5 \dim \mathrm{Row}(D) \log(1+b^2)\,\mathrm{budget}(D)$. Theorem C compares the two. A crude bound, $|h_{\mathrm{main}}(D)| + m\,|\mathrm{rem}(D)| \le b^2 x^{99}$, shows that replacing n by $\dim \mathrm{Row}(D)$ costs at most $4x^{99}$ for each row. Dividing by $\dim \mathrm{Row}(D)$, the main amount cancels:

$$m \cdot \mathrm{rem}(D) \;\le\; (4 \log b + 10 \log(1+b^2))\,\mathrm{budget}(D) + 4x^{99} \;\le\; (\log b)^2\,\mathrm{budget}(D).$$

5. The twists

Theorem C compares the lifts at the trivial twist with the lifts at twists where they have few congruences with other forms. The formal proof does not find one such twist for all primes: it finds one for each embedding, which is what the height of Section 4 allows.

Twists. In Settings 1 and 2, for all parameters P and all admissible data D for P there is a family $\theta = (\theta_{\ell,\iota})$ of m-fold twists of D, one for each prime ℓ and each field isomorphism $\iota\colon \mathbb{C} \to \bar{\mathbb{Q}}_\ell$, that is *fit for* D.

Fitness is defined in Chapter VIII; it has three clauses. The prime ℓ is prime to the norms of the primes in $Q(\theta_{\ell,\iota})$. For each i with $1 \le i \le m$ (Chapter VIII, like the formal text, calls this index j), the determinants that measure the ℓ-adic denominators of the orthogonal projection of integral forms to the space Z_i (the image, in the forms of the auxiliary pair, of the adjoint of the i-th lift at $\theta^i_{\ell,\iota}$ restricted to good forms), and to certain lines of lifts from U(1), are at most $e^{r'\eta_\ell}$ for each dimension, where r' is the rank of the auxiliary space ($r(D)$ for the good lifts, 1 for the lines), with real numbers η_ℓ whose sum over any finite set of primes is at most $\mathrm{budget}(D)/(m\,k(D))$. And for finitely many Hecke characters of U(1), the inverse ratios of twisted to untwisted L-values have height at most x^{999}.

Idea (the authors' comments; Chapter VIII). A denominator of the projection to theta lifts is a congruence between a lift and a form that is not a lift. By Ribet's method, in a form with congruent blocks and in any rank, such a congruence produces classes in Selmer groups of the Galois representations attached to the forms (attached in the weak sense of Chapter VII); these representations are an irreducible block plus a string of powers of the cyclotomic character. The even classes of these groups, where in the authors' words

Vandiver's conjecture lives, are never bounded. Twisting by an anticyclotomic character of ℓ-power order, ramified at new primes where a tie between inertia and Frobenius is imposed (an intermediate device, which the final twist releases), makes all the relevant Selmer groups short for the first m powers at once; Taylor–Wiles primes in a triangular arrangement remove the even classes, the odd parts of Tate–Shafarevich groups of abelian CM fields are bounded by one explicit integer (for the untwisted character the module is the unramified part, with no oddness condition), and the conditions at ℓ cost a loss that is controlled by lifting crystalline extension classes in large weight.

6. What is quoted

The repository separates the argument from a background library, which proves from Mathlib the known results that the argument needs, often in a weaker form that suffices. This write-up reads the argument and quotes the background. That is a choice of exposition, not an extra hypothesis: the formal proof contains proofs of all of it. The quoted results come from *analytic number theory* (Landau's theorem, the zero-free box for quadratic twists that is discussed below, a weak form of the Siegel–Walfisz theorem; from Mathlib, the functional equation and the non-vanishing on $\operatorname{Re} s = 1$); from *class field theory and Galois cohomology* (Artin reciprocity, Chebotarev's theorem, local Tate duality, the Greenberg–Wiles formula); from *complex multiplication* (theta functions of CM curves and their formal groups, Kronecker's limit formula, the Chowla–Selberg formula); from *automorphic forms* (reduction theory, the Weil representation and theta lifts, the Siegel–Weil and Rallis inner product formulas, discrete series); and from *Galois representations* (those of eigenforms on unitary groups, through Shimura varieties; p-adic Hodge theory with the Bloch–Kato conditions and Kisin modules; bounds of Kolyvagin–Rubin type). The catalogue at the end of this handout lists each result with a precise statement, its reference where the place is confirmed, and the relation of the formal statement to the published one: the theorem itself, a special case, or a weaker form.

Some quoted results stand outside these three relations: no published source in the form needed has been identified, so they are quoted from the formal library, with their statements in the chapters, and not from the literature. The first is the zero-free box of Section 2, one prime d in a class whose twists $\tilde{L}(s, \xi\chi_K)$ have no zero in a box for all characters ξ modulo M at once. The formal library proves it in two steps. The first is an estimate of zero-density type for each fixed character ξ, real or not: the number of the primes $d \le x$ with $d \equiv 7 \bmod 8$, prime to M, for which $\tilde{L}(\,\cdot\,, \xi\chi_K)$, $K = \mathbb{Q}(\sqrt{-d})$, has a zero in a given box to the right of the critical line is at most a constant times a power of x with exponent less than 1. The second adds these bounds over the characters ξ and sets them against the divergence of the sum of $1/p$ over the primes p of a residue class. The source that the formal text names, a zero-density theorem of Jutila, concerns real characters. It does not give the first step for a non-real ξ, whose twists are not real, and no published place for that step has been confirmed; its statement is in Chapter II. The others are in Chapter VIII: a bound for the odd parts of the Tate–Shafarevich groups of an abelian CM field by one explicit integer, uniform in the prime, the twist and the precision (Greither's theorem is an identity of characteristic ideals, and how it would give such a bound is not established); a finite set of Galois elements that detects the relevant cocycles; and the relations at split primes, with a lower bound for the number of relation families, together with the count of trivialised cocycles that supplies its hypothesis.

The theorems, and what one must trust

- **The five final theorems: the Riemann hypothesis and the generalised Riemann hypothesis for Dirichlet L-functions** (unit 155)
  read: note built, structured proofs checked. 5 declarations.

- **The statements: the Riemann hypothesis and the generalised Riemann hypothesis for Dirichlet L-functions, in three forms** (unit 153)
  read: note built, structured proofs checked. 4 declarations.

- **The inequality ($\star$), the one-sided bound for the remainder of the weighted prime sum, the generalised Riemann hypothesis, and the passage to the critical line** (unit 154)
  read: note built, structured proofs checked. 5 declarations, 62 proof lines.

READBACK NOTE 3

The five final theorems, and what one must trust

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The root of the artifact is a file of five theorems, each proved in one line: the Riemann hypothesis, in the formulation of the library and in the artifact's own; the non-vanishing of every Dirichlet L-function on the half-plane $\operatorname{Re} s > \frac{1}{2}$; and the statement that the zeros of these functions in the critical strip lie on the line $\operatorname{Re} s = \frac{1}{2}$, for all characters and for primitive ones. All five follow from one theorem, the zero-free half-plane, by the functional equations. This note states the five theorems, shows how each is obtained, and then says what one has to trust in order to believe them, and what that trust does not give.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, whose final theorems are stated below. That headline is a claim. The authors report that every file compiles with Lean v4.35.0 against a pinned version of the library Mathlib and that Lean's kernel accepted the proofs; an independent build is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note treats one unit of the artifact, its root: all 5 of its 5 declarations. Their proofs are given in full; they are deductions of one line from three results of another unit, which are stated as Inputs 1 to 3 and not proved here. Every statement was compared with its Lean text. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 12 declarations.

1 The five theorems

Throughout, ζ is the Riemann zeta function and $L(s, \chi)$ the L-function of a Dirichlet character χ, as the mathematical library of Lean defines them (§2).

Theorem 1 (the Riemann hypothesis, in the library's formulation). *For every complex number s with $\zeta(s) = 0$, such that there is no natural number n with $s = -2(n+1)$, and with $s \neq 1$:* $\operatorname{Re} s = \frac{1}{2}$.

Theorem 2 (the Riemann hypothesis, in the artifact's formulation). *For every complex number s: if $\zeta(s) = 0$, if there is no natural number n with $s = -2(n+1)$, and if $s \neq 1$, then* $\operatorname{Re} s = \frac{1}{2}$.

LEAN `riemannHypothesis` · `riemannZeta_eq_zero_re`

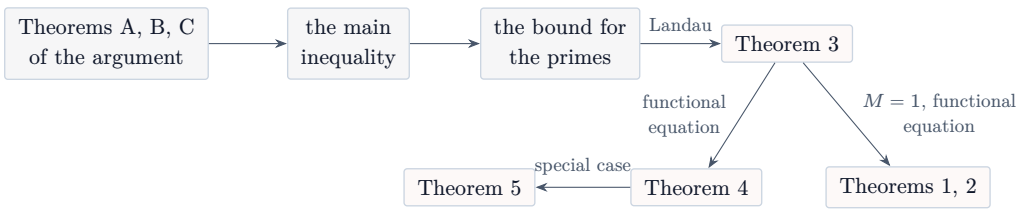
Theorem 3 (the zero-free half-plane). *For every integer $M \geq 1$, every Dirichlet character χ modulo M and every complex number s with $\operatorname{Re} s > \frac{1}{2}$: if χ is not the principal character modulo M or $s \neq 1$, then $L(s, \chi) \neq 0$.*

Theorem 4 (zeros in the critical strip). *For every integer $M \geq 1$, every Dirichlet character χ modulo M and every complex number s: if $0 < \operatorname{Re} s$, $\operatorname{Re} s < 1$ and $L(s, \chi) = 0$, then $\operatorname{Re} s = \frac{1}{2}$.*

Theorem 5 (zeros in the critical strip, primitive characters). *For every integer $M \geq 1$ and every Dirichlet character χ modulo M that is primitive, and for every complex number s: if $0 < \operatorname{Re} s$, $\operatorname{Re} s < 1$ and $L(s, \chi) = 0$, then $\operatorname{Re} s = \frac{1}{2}$.*

LEAN `LFunction_ne_zero_of_half_lt_re` · `LFunction_eq_zero_re` · `LFunction_eq_zero_re_of_isPrimitive`

Theorems 1 and 2 say the same thing: the first is stated with the proposition that the library itself calls the Riemann hypothesis, the second with the artifact's copy of it. Theorem 4 is the generalised Riemann hypothesis for Dirichlet L-functions in its usual form. Theorem 3 is the form in which the artifact proves it; it carries the whole argument, and the other four are deduced from it in §3.



The five theorems and what lies behind them. The grey boxes and the two arrows marked with functional equations are the subject of the note *The main inequality, the bound for the primes, and the zero-free half-plane*; Theorems A, B and C are the three main theorems of the argument (short forms, enough forms, integral forms are long) and are read in later chapters.

2 The setting

Conventions. The natural numbers are $0, 1, 2, \ldots$, and $\operatorname{Re} s$ is the real part of a complex number s. The declarations of this unit have no implicit arguments, so there is no ambient object to fix. The functions ζ and $L(s, \chi)$, Dirichlet characters, principal and primitive characters are those of Mathlib, the mathematical library of Lean, at the commit that the artifact pins. The note *The four statements: the Riemann hypothesis and its generalisation to Dirichlet L-functions* says what these objects are and what determines them. In short: ζ and $L(\cdot, \chi)$ are the analytic continuations of the series $\sum_{n \geq 1} n^{-s}$ and $\sum_{n \geq 1} \chi(n) n^{-s}$, with a conventional value at the pole $s = 1$ of ζ and of the L-function of a principal character; a Dirichlet character modulo M is a multiplicative map from $\mathbb{Z}/M$ to $\mathbb{C}$ that vanishes outside the units, the principal character is the one with value 1 at every unit, and a character is primitive when no character of a smaller modulus induces it.

Definition 2.1 (the four statements)**.** The artifact defines four propositions.

(1) *The Riemann hypothesis for ζ*: for every complex number s, if $\zeta(s) = 0$, if there is no natural number n with $s = -2(n + 1)$, and if $s \neq 1$, then $\operatorname{Re} s = \frac{1}{2}$.

(2) *The half-plane statement*: for every integer $M \geq 1$, every Dirichlet character χ modulo M and every complex number s with $\operatorname{Re} s > \frac{1}{2}$, if χ is not the principal character modulo M or $s \neq 1$, then $L(s, \chi) \neq 0$.

(3) *The strip statement*: for every integer $M \geq 1$, every Dirichlet character χ modulo M and every complex number s, if $0 < \operatorname{Re} s$, $\operatorname{Re} s < 1$ and $L(s, \chi) = 0$, then $\operatorname{Re} s = \frac{1}{2}$.

(4) *The strip statement for primitive characters*: for every integer $M \geq 1$ and every primitive Dirichlet character χ modulo M, and for every complex number s, if $0 < \operatorname{Re} s$, $\operatorname{Re} s < 1$ and $L(s, \chi) = 0$, then $\operatorname{Re} s = \frac{1}{2}$.

LEAN `RiemannZetaZerosOnLine` · `DirichletLNonvanishingRightOfHalf` · `DirichletLZerosOnLine` · `PrimitiveDirichletLZerosOnLine` · these four definitions form another unit, the subject of the note *The four statements*

Theorems 2, 3, 4 and 5 assert propositions (1), (2), (3) and (4), in this order. Theorem 1 asserts a proposition of the library, whose text agrees with (1) word for word, up to the way in which the number $n + 1$ is read as a complex number.

Inputs from another unit. The three results below are taken for granted in this note. They belong to the unit that ends the argument; they are proved in the note *The main inequality, the bound for the primes, and the zero-free half-plane*, the first from the main theorems of the argument, the other two completely.

Input 1 (the zero-free half-plane). *The half-plane statement holds.*

Input 2 (from the half-plane to the strip). *If the half-plane statement holds, then the strip statement holds.*

Input 3 (from the half-plane to ζ). *If the half-plane statement holds, then the Riemann hypothesis for ζ holds.*

LEAN `New.grh` · `New.zeros_on_line` · `New.zeta_zeros_on_line`

Input 1 is the main theorem of the artifact. Inputs 2 and 3 are classical: the functional equation of the completed L-function reflects a zero s with $0 < \operatorname{Re} s < \frac{1}{2}$ to the zero $1 - s$ of the L-function of the inverse character, and for $M = 1$ the L-function is ζ.

3 Proofs

Proof of Theorem 3. It is Input 1. □

Proof of Theorem 4. By Input 1 the half-plane statement holds, and by Input 2 the strip statement follows. □

Proof of Theorems 1 and 2. By Input 1 the half-plane statement holds, and by Input 3 the Riemann hypothesis for ζ follows. This is Theorem 2, and it is Theorem 1 because the proposition of the library and proposition (1) of Definition 2.1 are the same. □

Proof of Theorem 5. Let $M \geq 1$ be an integer and χ a primitive Dirichlet character modulo M. Theorem 4, applied to M and χ, gives the assertion for every complex number s. That χ is primitive is not used. □

LEAN each of the five formal proofs is one term · the terms use `New.grh`, `New.zeros_on_line` and `New.zeta_zeros_on_line` exactly as above

4 What one must trust

The five theorems are short to state, and their formal proof is very long. What does a reader have to accept in order to believe them, short of reading the proof? Four things, of different kinds.

1. That the statements mean what they say. The four propositions of Definition 2.1 are written in a file that uses the library and nothing else, and the root file states the five theorems with these propositions and with the library's own. So what is claimed can be read off two short files, and it rests on the library's definitions of ζ, of Dirichlet characters and of their L-functions. No definition made by the artifact enters a statement: all its other definitions occur only inside proofs. The library's functions are defined at every complex number, also at a pole, and the statements exclude the poles explicitly. The note *The four statements* goes through this.

2. The library. One trusts that the library's ζ and $L(s, \chi)$ are the classical functions. This is not a matter of faith in a construction: the library proves that they agree with the Dirichlet series for $\operatorname{Re} s > 1$ and are holomorphic away from the pole, and these two properties determine them. What one accepts is that these theorems of the library are themselves correctly checked, which is the next point.

3. The kernel and the axioms. A proof in Lean is a term that a small program, the kernel, checks against the statement. The authors report three things: every file of the artifact compiles with the pinned versions of Lean and of the library, without errors and without the placeholder that Lean accepts for a missing proof; the five theorems depend on no axiom other than the three standard ones of Lean with classical logic (propositional extensionality, the soundness of quotients, and the axiom of choice); and an independent tool, which compares a file holding only the five statements with the root file and checks the proofs again, accepted them. These are the authors' reports, read in the description that accompanies the artifact. On our side, a reading of the text of all files of the artifact, made when this workspace was set up, found no placeholder and no declaration of an axiom, and an independent build with the same versions is recorded in the handout's record of checks when it reports. Which axioms a proof rests on is for the kernel to say, not for a reading of the text. To accept the result on this ground is to trust the kernel of Lean, its implementation, and the three axioms.

4. Nothing about the argument. A kernel check establishes that the stated theorems follow from the axioms. It does not tell a mathematician why they hold, and it is not a reading: at the time of writing nobody has read the argument through. The purpose of this write-up is to make that reading possible. Each of its notes says what was compared with the Lean text by a program, what was read by a person, and what is taken for granted from other units; the map of the handout shows which units have been read.

5 Notes on the formal text

1. *The five proofs are terms.* Theorem 3 is proved by the name of Input 1 alone: it is the same theorem under a second name. Theorem 4 is Input 2 applied to Input 1. Theorem 1 is Input 3 applied to Input 1. Theorem 2 is proved by the name of Theorem 1. Theorem 5 takes the modulus, the assumption that it is not zero, the character and the assumption that it is primitive, and returns Theorem 4 for that modulus and character.
2. *Two formulations of the Riemann hypothesis.* Input 3 concludes proposition (1) of Definition 2.1, and Theorem 1 is stated with the proposition of the library; conversely Theorem 2 is stated with (1) and proved by Theorem 1. Lean accepts both steps only if the two propositions agree after unfolding their definitions. So the acceptance of the file is also a check that the artifact's copy is the library's formulation.
3. *The hypothesis of Theorem 5.* The assumption that the character is primitive is received and not used. Theorem 5 is stated because the generalised Riemann hypothesis is often formulated for primitive characters only; for the zeros with $0 < \operatorname{Re} s < 1$ the two formulations are equivalent, as the note *The four statements* explains.
4. *The modulus.* The formal text writes the modulus as a natural number N with the assumption $N \neq 0$, passed as an instance argument. Here it is an integer $M \geq 1$; the letter N is kept in this write-up for the level of the automorphic forms of the proof.
5. *Authorship.* The root file carries one comment: the proof is Levent Alpöge's, with Claude. The description of the artifact adds that the Lean text and the accompanying documents were written by Claude, and that this edition is a shorter rewriting of an earlier formal proof by Alpöge.

How this note was written. From the dossier of the unit. It has no structured proof, because each of the five formal proofs is a single term; the program check of the dossier covered 0 leaf steps of 0 proofs, found the five statements at their lines and compared the quotations of the imported declarations with the source. I read the whole root file and the whole file of the four statements, and the statements of the three inputs in their file. For §4 I read the description that accompanies the artifact, the file of five statements without proofs that it provides for the comparison tool, the configuration of that tool, and the files that pin the versions of Lean and of the library; I also read the library's formulation of the Riemann hypothesis in the library's public repository at the pinned commit. I did not run a build. The diagram and §4 are mine.

lemma New.zeros_on_line (h : DirichletLNonvanishingRightOfHalf) : DirichletLZerosOnLine

lemma New.zeta_zeros_on_line (h : DirichletLNonvanishingRightOfHalf) :
    RiemannZetaZerosOnLine
```

In these texts `RiemannHypothesis` is the proposition of the library, in the namespace of the library; the four other propositions are those of Definition 2.1, and the table above gives their names in the order (1) to (4). The library's proposition is not quoted here, because the build of this note copies quotations from the artifact only; it is to be read in the library, in the file of the Riemann zeta function.

Notation

- s, $\operatorname{Re} s$ a complex number; its real part
- n a natural number, $n \geq 0$
- ζ the Riemann zeta function, as the library defines it
- M the modulus of a Dirichlet character, an integer ≥ 1
- χ a Dirichlet character modulo M
- $L(s, \chi)$ the L-function of the Dirichlet character χ, as the library defines it
- N the modulus in the formal text; in this note it is M

READBACK NOTE 2

The four statements: the Riemann hypothesis and its generalisation to Dirichlet L-functions

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The headline of the artifact is five theorems. Their statements are four propositions about the Riemann zeta function and the Dirichlet L-functions, written in one short file that uses nothing but the mathematical library of Lean: the Riemann hypothesis for ζ; the non-vanishing of every Dirichlet L-function on the half-plane $\operatorname{Re} s > \frac{1}{2}$; and the statement that the zeros of these functions in the critical strip lie on the line $\operatorname{Re} s = \frac{1}{2}$, for all characters and for primitive ones. This note states the four propositions in ordinary language, says which objects of the library they speak of and what determines those objects, and records how the four are related: the second implies the other three.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, whose final theorems are the Riemann hypothesis and its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles with Lean v4.35.0 against a pinned version of the library Mathlib and that Lean's kernel accepted the proofs; an independent build is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note treats one unit of the artifact: all 4 of its 4 declarations, which are definitions of propositions. The unit proves nothing, so there is no proof to read and nothing is taken for granted from other units. Each of the four statements was compared with its Lean text, and the objects of the library that they use were compared with the library's source at the pinned commit (Appendix A says exactly what was read). The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 4 declarations.

1 The four statements

Throughout, ζ is the Riemann zeta function and $L(s, \chi)$ is the L-function of a Dirichlet character χ, as the library defines them; §2 says what these functions are. The first statement is about ζ, the other three are about the L-functions.

Statement 1 (the Riemann hypothesis for ζ). *For every complex number s: if $\zeta(s) = 0$, if there is no natural number n with $s = -2(n+1)$, and if $s \neq 1$, then* $\operatorname{Re} s = \frac{1}{2}$.

LEAN `RiemannZetaZerosOnLine`

Statement 2 (the half-plane statement). *For every integer $M \geq 1$, every Dirichlet character χ modulo M and every complex number s with $\operatorname{Re} s > \frac{1}{2}$: if χ is not the principal character modulo M or $s \neq 1$, then $L(s, \chi) \neq 0$.*

Statement 3 (the strip statement). *For every integer $M \geq 1$, every Dirichlet character χ modulo M and every complex number s: if $0 < \operatorname{Re} s$, $\operatorname{Re} s < 1$ and $L(s, \chi) = 0$, then $\operatorname{Re} s = \frac{1}{2}$.*

Statement 4 (the strip statement for primitive characters). *For every integer $M \geq 1$ and every Dirichlet character χ modulo M that is primitive, and for every complex number s: if $0 < \operatorname{Re} s$, $\operatorname{Re} s < 1$ and $L(s, \chi) = 0$, then $\operatorname{Re} s = \frac{1}{2}$.*

LEAN `DirichletLNonvanishingRightOfHalf` · `DirichletLZerosOnLine` · `PrimitiveDirichletLZerosOnLine`

Each of the four is a proposition, not a theorem: the unit defines them and asserts nothing. They are asserted by the five final theorems of the artifact, which are the subject of the note *The five final theorems, and what one must trust.* The argument is for Statement 2; its last steps, and the passage from Statement 2 to Statements 1 and 3, are the subject of the note *The main inequality, the bound for the primes, and the zero-free half-plane.*

In classical terms, Statement 1 is the Riemann hypothesis, and Statement 3 is the generalised Riemann hypothesis for Dirichlet L-functions in its usual form, for the zeros in the open critical strip. Statement 2 is the form in which the artifact proves it: a zero-free half-plane. It contains the classical non-vanishing on the closed half-plane $\operatorname{Re} s \geq 1$, and beyond that it says that there is no zero with $\frac{1}{2} < \operatorname{Re} s < 1$.

2 The objects of the statements

Conventions. The natural numbers are $0, 1, 2, \ldots$, and $\operatorname{Re} s$ is the real part of a complex number s. The declarations of this unit have no arguments, so there is no ambient object to fix. Everything that the four statements speak of is defined in Mathlib, the mathematical library of Lean, at the commit that the artifact pins; nothing in them is defined by the artifact. Appendix A gives the library's names for the objects and facts of this section.

The zeta function. The library's zeta function is a function $\zeta\colon \mathbb{C} \to \mathbb{C}$, defined at every complex number. It is constructed from Hurwitz zeta functions, and the library proves the following about it.

(a) For $\operatorname{Re} s > 1$, $\zeta(s) = \sum_{n \geq 1} n^{-s}$.
(b) ζ is complex differentiable at every $s \neq 1$, and $(s-1)\zeta(s) \to 1$ as $s \to 1$.
(c) $\zeta(-2(n+1)) = 0$ for every natural number n, and $\zeta(0) = -\frac{1}{2}$.

By (a), (b) and the identity theorem, the restriction of ζ to $\mathbb{C} \setminus \{1\}$ is *the* analytic continuation of the series: the two properties determine it. A function of Lean must have a value everywhere, so the library also assigns a value to ζ at the pole $s = 1$; that value is a convention, and no statement of this note depends on it, because Statement 1 excludes $s = 1$. The zeros in (c) are the trivial zeros $-2, -4, -6, \ldots$; they are what the second hypothesis of Statement 1 excludes.

Dirichlet characters. Let $M \geq 1$ be an integer. A *Dirichlet character modulo M* (with complex values) is a map $\chi\colon \mathbb{Z}/M \to \mathbb{C}$ with $\chi(1) = 1$ and $\chi(uv) = \chi(u)\chi(v)$ for all classes u and v, and with $\chi(u) = 0$ for every class u that is not a unit. It is evaluated at an integer through the class of the integer. The *principal character* modulo M takes the value 1 at every unit; in the library it is the unit element 1 of the group of characters. For $M = 1$ the ring $\mathbb{Z}/1$ has one element, which is a unit, and the principal character is the only character. If M_0 divides M, a character modulo M_0 *induces* a character modulo M, by composition with the reduction of units. The *conductor* of a character χ modulo M is the least divisor M_0 of M such that χ is induced by a character modulo M_0, and χ is *primitive* when its conductor is M. Every character modulo M is induced by exactly one primitive character, whose modulus is the conductor.

Dirichlet L-functions. For an integer $M \geq 1$ and a Dirichlet character χ modulo M, the library's L-function is a function $s \mapsto L(s, \chi)$ from $\mathbb{C}$ to $\mathbb{C}$, defined at every complex number. It is constructed as a linear combination of Hurwitz zeta functions, and the library proves the following.

(a) For $\operatorname{Re} s > 1$, $L(s, \chi) = \sum_{n \geq 1} \chi(n)\, n^{-s}$.

(b) $s \mapsto L(s, \chi)$ is complex differentiable at every s, except possibly at $s = 1$ when χ is principal.

(c) For $M = 1$, $L(s, \chi) = \zeta(s)$ for every complex number s.

(d) If χ_0 is a character modulo a divisor M_0 of M and χ is the character modulo M that it induces, then for every complex number s such that χ_0 is not principal or $s \neq 1$,

$$L(s, \chi) = L(s, \chi_0) \prod_{p \mid M} (1 - \chi_0(p)\, p^{-s}),$$

the product over the primes p that divide M.

So for a character that is not principal, $L(\,\cdot\,, \chi)$ is the entire function that continues the series. For a principal character it is the continuation to $\mathbb{C} \setminus \{1\}$, with a simple pole at 1, and its value at $s = 1$ is again a convention; this is why Statement 2 excepts the point $s = 1$ for a principal character, and only that point.

3 How the four statements are related

The unit contains no proof. What follows is said for orientation; the proofs are in the notes named.

Statement 2 implies the other three. Statement 2 implies Statement 3: a zero s with $0 < \operatorname{Re} s < \frac{1}{2}$ would be reflected by the functional equation to the zero $1 - s$ of the L-function of the inverse character, which lies in the half-plane of Statement 2. Statement 2 for $M = 1$ implies Statement 1, by property (c) of the L-functions and the functional equation of ζ. These two implications are Theorems 4 and 5 of the note *The main inequality, the bound for the primes, and the zero-free half-plane.* Statement 3 implies Statement 4, which is its special case for primitive characters. The artifact proves Statement 2 and deduces the other three in this way.

Remark 3.1 (what Statements 2 to 4 leave out)**.** Statements 2, 3 and 4 say nothing about zeros with $\operatorname{Re} s \leq 0$. There the L-function of a character has its trivial zeros, and the L-function of a character that is not primitive can have further zeros on the line $\operatorname{Re} s = 0$: those of the factors $1 - \chi_0(p)p^{-s}$ of property (d), with χ_0 the primitive character that induces it, for the primes p that divide the modulus but not the conductor. For the other primes p dividing the modulus, $\chi_0(p) = 0$ and the factor is 1; so a character whose modulus and conductor have the same prime divisors, for instance a character modulo 9 of conductor 3, has no further zero. Statement 1 does speak of all zeros of ζ: it says that a zero is a trivial zero or lies on the line $\operatorname{Re} s = \frac{1}{2}$.

Remark 3.2 (characters that are not primitive)**.** The statements are made for all characters, primitive or not. This costs nothing and gains nothing. Let χ be a character modulo M and χ_0 the primitive character that induces it. A factor $1 - \chi_0(p)p^{-s}$ of property (d) vanishes only if $|\chi_0(p)| = p^{\operatorname{Re} s}$; the left side is 0 or 1, so this forces $\operatorname{Re} s = 0$. Hence for $\operatorname{Re} s > 0$, and $s \neq 1$ when χ is principal, $L(s, \chi) = 0$ if and only if $L(s, \chi_0) = 0$. So Statement 3 is equivalent to Statement 4, and Statement 2 is equivalent to its restriction to primitive characters. For a principal character, χ_0 is the character modulo 1, whose L-function is ζ: Statements 2 and 3 contain the corresponding statements for ζ. This remark is ours and is not a declaration of the unit; the artifact proves only that Statement 3 implies Statement 4.

4 Notes on the formal text

1. *The file.* The four definitions are the whole content of one file, whose only import is the library. So the meaning of the four statements rests on the library alone, not on any definition of the artifact. This is by design: it is the file to read in order to know what is claimed.
2. *The modulus.* The formal text writes the modulus as a natural number N together with the assumption $N \neq 0$, which Lean passes as an instance argument; this is "every integer $M \geq 1$" above. The letter N is kept in this write-up for the level of the automorphic forms of the proof, and a modulus is written M throughout, as in the weighted prime sums of the argument.
3. *Statement 1 and the library's own formulation.* The library contains a formulation of the Riemann hypothesis as a proposition. Statement 1 is that proposition, written out again in the artifact: the two texts differ only in how the number $n + 1$ is read as a complex number. The first of the five final theorems has the library's proposition as its statement and the second has Statement 1; the artifact proves the second by citing the first, which Lean accepts only if the two propositions agree after unfolding.
4. *The trivial zeros.* They appear as "there is no natural number n with $s = -2(n + 1)$", that is, $s \notin \{-2, -4, -6, \dots\}$.
5. *The pole.* In Statement 1 the hypothesis $s \neq 1$ excludes the point where the value of ζ is a convention. In Statement 2 the hypothesis reads "χ is not the unit element of the group of characters, or $s \neq 1$"; it excludes exactly the pole of a principal character. Statements 3 and 4 need no such hypothesis, because $\operatorname{Re} s < 1$ there.

6. *The strip.* In Statements 3 and 4 the strip is open, and the two inequalities $0 < \operatorname{Re} s$ and $\operatorname{Re} s < 1$ are two separate hypotheses, in this order, before the hypothesis $L(s, \chi) = 0$.
7. *Order of the quantifiers.* Statement 4 takes the modulus, the character and the hypothesis that the character is primitive before the complex number s; Statements 2 and 3 take the modulus, the character and then s. Nothing depends on this order here.
8. *Real numbers.* The real part is a real number, and $\frac{1}{2}$ is the real number one half.

How this note was written. From the dossier of the unit, which has no structured proof because the unit has no proof; the program check of the dossier covered 0 leaf steps of 0 proofs and found the four statements at their lines. I read the whole file of the unit in the artifact and compared each of the four statements above with it, clause by clause. For the objects of the library I read, in the library's public repository at the commit that the artifact pins, the declarations listed in the second table of Appendix A: their statements and the comments above them, not their proofs, and not the construction of the Hurwitz zeta functions from which ζ and the L-functions are made. The dossier describes the same objects from memory and says so; its descriptions agree with what I read. The two remarks of §3 are mine.

Appendix A. Concordance with the Lean artifact

In this note	Lean declaration	File	Lines
Statement 1	`RiemannZetaZerosOnLine`	Statements.lean	3–4
Statement 2	`DirichletLNonvanishingRightOfHalf`	Statements.lean	6–8
Statement 3	`DirichletLZerosOnLine`	Statements.lean	10–12
Statement 4	`PrimitiveDirichletLZerosOnLine`	Statements.lean	14–16

The four statements as they are written in the artifact. Statement 1:

```
def RiemannZetaZerosOnLine : Prop :=
  ∀ s : ℂ, riemannZeta s = 0 → (¬∃ n : ℕ, s = -2 * ((n : ℂ) + 1)) → s ≠ 1 → s.re = 1 / 2
```

Statement 2:

```
def DirichletLNonvanishingRightOfHalf : Prop :=
  ∀ (N : ℕ) [NeZero N] (χ : DirichletCharacter ℂ N) (s : ℂ),
    1 / 2 < s.re → (χ ≠ 1 ∨ s ≠ 1) → DirichletCharacter.LFunction χ s ≠ 0
```

Statement 3:

```
def DirichletLZerosOnLine : Prop :=
  ∀ (N : ℕ) [NeZero N] (χ : DirichletCharacter ℂ N) (s : ℂ),
    0 < s.re → s.re < 1 → DirichletCharacter.LFunction χ s = 0 → s.re = 1 / 2
```

Statement 4:

```
def PrimitiveDirichletLZerosOnLine : Prop :=
  ∀ (N : ℕ) [NeZero N] (χ : DirichletCharacter ℂ N), χ.IsPrimitive →
    ∀ s : ℂ, 0 < s.re → s.re < 1 → DirichletCharacter.LFunction χ s = 0 → s.re = 1 / 2
```

In these texts the modulus is N, the letter `ℂ` stands for the complex numbers and `ℕ` for the natural numbers, `s.re` is $\operatorname{Re} s$, `χ ≠ 1` says that χ is not the principal character, and `[NeZero N]` is the assumption $N \neq 0$.

The objects of the library. The library is Mathlib at the commit that the artifact pins in its manifest. The declarations below were read there for this note; the left column says what each one is in §2.

In this note	Declaration of the library
the function ζ	`riemannZeta`
ζ, property (a)	`zeta_eq_tsum_one_div_nat_cpow`
ζ, property (b)	`differentiableAt_riemannZeta, riemannZeta_residue_one`

L, property (d)	`DirichletCharacter.LFunction_changeLevel`

Notation

s, $\operatorname{Re} s$ a complex number; its real part

n a natural number, $n \geq 0$

ζ the Riemann zeta function, as the library defines it

M, M_0 moduli of Dirichlet characters, integers ≥ 1; M_0 a divisor of M

χ, χ_0 Dirichlet characters modulo M and modulo M_0

u, v classes in $\mathbb{Z}/M$

$L(s, \chi)$ the L-function of the Dirichlet character χ, as the library defines it

p a prime number

N the modulus in the formal text; in this note it is M

READBACK NOTE 4

The main inequality, the bound for the primes, and the zero-free half-plane

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. This unit is the top of the argument. Its first result, the main inequality, bounds a remainder of weighted sums over primes: $m \cdot \mathrm{rem}(D) \le (\log b)^2 \cdot \mathrm{budget}(D)$ for all admissible data D of the proof. It comes from bounding one covolume from two sides: Theorems A and B of the argument give many independent automorphic forms with short theta lifts, Theorem C says that such lifts cannot be that short, and in the comparison the main amounts cancel. Letting the data grow, with the second scale at a good point of a long window, one gets the one-sided bound $R_{d,N_0}(x) \le x^{8\varepsilon-1/2}$ for the remainder of a smoothed sum over the prime powers $\nu \equiv 1$ modulo N_0, weighted by $\Lambda(\nu)(1-\chi_K(\nu))$ (Definition 2.5); the saving $x^{-1/2}$ is the reciprocal of the number m of lifts. A criterion of Landau turns this bound, for all primes d of one residue class, into the absence of zeros of Dirichlet L-functions in the half-plane $\mathrm{Re}\, s > \frac{1}{2}$, and the functional equations put the nontrivial zeros on the critical line.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, whose final theorems are the Riemann hypothesis and its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles with Lean v4.35.0 against a pinned version of the library Mathlib and that Lean's kernel accepted the proofs; an independent build is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note treats one unit of the artifact: all 5 of its 5 declarations, Theorems 1 to 5 below. Their proofs are complete *given* eleven results of other units, which are stated as Inputs 1 to 11 with the unit that owns each and are not proved here; among them are the three main theorems of the argument (Inputs 1 and 2) and Landau's criterion (Input 10). Every statement of the unit and of the Inputs was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 48 declarations.

1 The statements

The objects in the five theorems are defined in §2: parameters and admissible data in Definitions 2.2 to 2.4, the remainders $R_{d,M}(x)$ and $\mathrm{rem}(D)$ in Definitions 2.5 and 2.6, the three statements in Definition 2.1.

Theorem 1 (the main inequality). *Let P be parameters and D admissible data for P, with number of lifts m and third scale b. Then*

$$m \cdot \mathrm{rem}(D) \;\le\; (\log b)^2 \cdot \mathrm{budget}(D).$$

Here $\mathrm{rem}(D)$ *is the remainder of the weighted prime sums of* D*, and* $\mathrm{budget}(D) = f(D) \cdot a(D) \cdot (\log b)^3$ *is its budget.*

LEAN `star_inequality`

Theorem 2 (the bound for the primes). *Let $P = (N_0, d)$ be parameters and ε a real number with $0 < \varepsilon/6$ and $\varepsilon < \frac{1}{100}$. Then for every sufficiently large real number x,*

$$R_{d,N_0}(x) \;\le\; x^{\,8\varepsilon+\frac{1}{2}-1}.$$

LEAN `eventually_primeError_le_rpow`

Theorem 3 (the zero-free half-plane). *The half-plane statement holds: for every integer $M \ge 1$, every Dirichlet character χ modulo M and every complex number s with $\mathrm{Re}\, s > \frac{1}{2}$, if χ is not the principal character modulo M or $s \ne 1$, then $L(s,\chi) \ne 0$.*

Theorem 4 (from the half-plane to the strip). *If the half-plane statement holds, then the strip statement holds: for every integer $M \ge 1$, every Dirichlet character χ modulo M and every complex number s with $0 < \mathrm{Re}\, s$, $\mathrm{Re}\, s < 1$ and $L(s,\chi) = 0$, one has $\mathrm{Re}\, s = \frac{1}{2}$.*

Theorem 5 (from the half-plane to ζ). *If the half-plane statement holds, then the Riemann hypothesis for ζ holds: every complex number s with $\zeta(s) = 0$, such that there is no natural number n with $s = -2(n+1)$, and with $s \ne 1$, has $\mathrm{Re}\, s = \frac{1}{2}$.*

LEAN `New.grh` · `New.zeros_on_line` · `New.zeta_zeros_on_line`

Theorem 3 is the main theorem of the artifact. Theorems 3, 4 and 5 together give the five final theorems, which are the subject of the note *The five final theorems, and what one must trust.*

The plan of the proof. The argument attaches to the data D a finite-dimensional space of automorphic forms, the *rows*, and a linear map on it, the composite of m theta lifts. Theorems A and B of the argument, taken together (Input 1), give linearly independent rows that almost span, have small index with respect to the integral structures, and have short lifts: the squared covolume of the lifts is at most $\exp(n\,(h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \mathrm{error}))$ at every conjugate, where n is the number of the rows and $h_{\mathrm{main}}(D)$ is the main amount. Theorem C (Input 2) is a bound in the other direction, a consequence of the product formula: integral forms are long. If the squared covolumes of the lifts of such rows are at most $\exp(V)$ at every conjugate, then V, plus twice a bound for the index, is at least $\dim \mathrm{Row}(D) \cdot (h_{\mathrm{main}}(D) - \mathrm{error})$. The two bounds can hold together only if $m \cdot \mathrm{rem}(D)$ is at most the sum of the

errors. This is Theorem 1, and it is all that the rest of the argument needs from the automorphic side.

The remainder $\mathrm{rem}(D)$ is a combination of remainders of weighted prime sums at the first two scales of the data (Input 6). For large x there are data with first scale x (Input 7), and the second scale can be moved to a point where the unwanted values are negligible (Input 9). Then Theorem 1, divided by m and by the other positive factors, is Theorem 2. Landau's criterion (Input 10) gives Theorem 3, and the functional equations give Theorems 4 and 5.

2 The setting

Conventions. The natural numbers are $0, 1, 2, \ldots$; $\mathrm{Re}\, s$ is the real part of a complex number s; log is the natural logarithm, and powers of positive real numbers with real exponents are defined through it; φ is Euler's function and Λ von Mangoldt's function. A statement holds *for every sufficiently large* real number if there is a real number such that it holds for every real number at least as large. The Riemann zeta function ζ, Dirichlet characters and their L-functions $L(s, \chi)$ are those of Mathlib, the mathematical library of Lean, at the commit that the artifact pins; the note *The four statements: the Riemann hypothesis and its generalisation to Dirichlet L-functions* says what determines them. A modulus is an integer $M \geq 1$. Parameters are called P and admissible data for P are called D; a statement about D is a statement for every P and all such D, and the components of P and of D are named where they are used.

The three statements.

Definition 2.1 (three propositions)**.** (1) The *Riemann hypothesis for* ζ: for every complex number s, if $\zeta(s) = 0$, if there is no natural number n with $s = -2(n+1)$, and if $s \neq 1$, then $\mathrm{Re}\, s = \frac{1}{2}$. (2) The *half-plane statement*: for every integer $M \geq 1$, every Dirichlet character χ modulo M and every complex number s with $\mathrm{Re}\, s > \frac{1}{2}$, if χ is not the principal character modulo M or $s \neq 1$, then $L(s, \chi) \neq 0$. (3) The *strip statement*: for every integer $M \geq 1$, every Dirichlet character χ modulo M and every complex number s, if $0 < \mathrm{Re}\, s$, $\mathrm{Re}\, s < 1$ and $L(s, \chi) = 0$, then $\mathrm{Re}\, s = \frac{1}{2}$.

LEAN `RiemannZetaZerosOnLine` · `DirichletLNonvanishingRightOfHalf` · `DirichletLZerosOnLine` · another unit; see the note *The four statements*

Parameters and data.

Definition 2.2 (parameters)**.** *Parameters* are a pair $P = (N_0, d)$ of natural numbers such that 18480 divides N_0, d is a prime number, N_0 divides $2(d+1)$, and N_0 does not divide $d+1$. For parameters $P = (N_0, d)$ we write $K = \mathbb{Q}(\sqrt{-d})$, a subfield of $\mathbb{C}$, and χ_K for the quadratic character of the field $\mathbb{Z}/d$, a Dirichlet character modulo d; it is the Legendre symbol $(\cdot/d)$ when d is odd, as it is for all parameters (Lemma 4.2).

LEAN `Parameters` · unit 152

The last two conditions say that $d \equiv N_0/2 - 1$ modulo N_0; they force $N_0 \geq 1$. Since $18480 = 2^4 \cdot 3 \cdot 5 \cdot 7 \cdot 11$, one has $d \equiv 7$ modulo 8 (Lemma 4.2); so K is an imaginary quadratic field in which 2 splits, and χ_K is its quadratic character.

Definition 2.3 (admissible data)**.** Let $P = (N_0, d)$ be parameters. The artifact attaches to P a real number $C(P)$, of which this note uses only Input 5. *Admissible data for P* are a record D with the following components.

(a) Three real numbers $\log x$, $\log x_1$ and $\log b$. Their exponentials x, x_1 and b are the first, second and third *scale* of D.

(b) Two natural numbers: m, the *number of lifts*, and r, a rank. By condition (ii) below, m is a power of 2; put

$$N_1(D) = N_0 \cdot m^{22} \cdot 3^{\lfloor \log_3(22 \log_2 m) \rfloor + 5},$$

and let $E(D)$ be the field generated over K by the roots of unity of order $N_1(D)$.

(c) A finite set $\mathrm{thick}(D)$ of infinite places of the field $E(D)$, the *thick* places.

(d) Two prime numbers and an element of the ring of integers of K.

They are subject to the following conditions.

(i) *The scales.*

$$10^{12}\, C(P) \le \log\log b, \qquad 100\, \log\log b \le \log x, \qquad 10^6\, \log x \le \log x_1,$$
$$10^6\, \log x_1 \le \log b, \qquad 6\, \log\log x_1 \le \log\log b.$$

(ii) *The number of lifts and the rank.* m is a power of 2 with exponent at least 1, $\sqrt{x} \le m \le 2\sqrt{x}$ and $22 \log_2 m \le 32 \log x$; r is a power of 3 with exponent at least 1, and $x^5 \le r \le 3\, x^5$.

(iii) *Further conditions,* on the classes of the thick places (a congruence, and the absence of certain relations between three of them), on the two primes and the integer of (d) (the primes are distinct, satisfy congruences and lie between b^{10} and b^{11}, and the norm of the integer is their product), and the existence of primes in certain short intervals.

The conditions (iii) are stated in full in the note on the data of the proof. In this note they matter only through the Inputs, and through one fact that was checked in the Lean text: $\log x_1$ occurs in the conditions (i) and nowhere else.

LEAN Data · Parameters.c · Data.N₁ · Data.E · unit 152

The conditions (i) put the scales far apart, $(\log b)^{100} \le x$, $x^{10^6} \le x_1$, $x_1^{10^6} \le b$, and make all of them very large (Lemma 3.1). The number $N_1(D)$ and the field $E(D)$ depend only on P and m. The formal record has one more component, a natural number called the exponent, which a condition makes equal to $22 \log_2 m$; this note does not give it a letter (§8, note 3). In the formal text the quotient $N_1(D)/N_0$ is the degree of a tower of fields, a function of the exponent.

Definition 2.4 (quantities derived from the data)**.** Let $P = (N_0, d)$ be parameters and D admissible data for P, with scales x, x_1, b.

(a) Every infinite place of $E(D)$ is the place of exactly one embedding $E(D) \to \mathbb{C}$ that is the identity on K. The Galois group of $E(D)$ over K permutes these embeddings simply transitively, and its action on the roots of unity identifies it with $(\mathbb{Z}/N_1(D))^\times$. (Restriction to the field generated over $\mathbb{Q}$ by these roots of unity is an isomorphism onto the Galois group of that field over $\mathbb{Q}$, because the quadratic field K is not contained in it: the prime d ramifies in K, and it

does not ramify in a field of roots of unity of order prime to d. And d is prime to $N_1(D)$: it is prime to N_0 by Lemma 4.2, and $N_1(D)$ has the same prime divisors as N_0, since m is a power of 2 and 6 divides N_0.) The artifact chooses one of the embeddings once. Each infinite place τ of $E(D)$ then has a *class* $\mathrm{cl}_D(\tau) \in (\mathbb{Z}/N_1(D))^\times$, the chosen embedding has class 1, and $\tau \mapsto \mathrm{cl}_D(\tau)$ is a bijection. For an integer ν prime to $N_1(D)$, $\nu \cdot \tau$ is the place whose class is ν times that of τ; for the other integers ν we put $\nu \cdot \tau = \tau$.

(b) $\mathrm{tops}(D)$, the set of *tops*, is the set of the infinite places τ of $E(D)$ whose class $\mathrm{cl}_D(\tau)$ is congruent to 1 modulo N_0.

(c) $f(D)$ is the number of infinite places of the field $E(D)$.

(d) $a(D)$ is the least multiple of $N_1(D)$ that is at least $x\,b$; it is a natural number.

(e) $\mathrm{budget}(D) = f(D) \cdot a(D) \cdot (\log b)^3$ is the *budget*.

LEAN Data.tops · Data.f · Data.a · Data.budget · unit 152

The weighted prime sums.

Definition 2.5 (the weight, and the remainder of the prime sum)**.** Let d be a prime number and $M \geq 1$ an integer; $K = \mathbb{Q}(\sqrt{-d})$, and χ_K is the quadratic character of the field $\mathbb{Z}/d$, a Dirichlet character modulo d (the Legendre symbol $(\,\cdot\,/d)$ when d is odd).

(a) For a natural number ν put $\lambda_{d,M}(\nu) = \Lambda(\nu)(1 - \chi_K(\nu))$ if $\nu \equiv 1$ modulo M, and $\lambda_{d,M}(\nu) = 0$ otherwise.

(b) For a Dirichlet character χ modulo an integer $M \geq 1$, let $s \mapsto \tilde{L}(s,\chi)$ be the following entire function: $\tilde{L}(s,\chi) = L(s,\chi)$ if χ is not principal; if χ is principal, $\tilde{L}(s,\chi) = (s-1)L(s,\chi)$ for $s \neq 1$, and $\tilde{L}(1,\chi) = \prod_{p \mid M}(1 - p^{-1})$, the product over the primes p dividing M.

(c) Put

$$\kappa_{d,M} = \frac{1}{\varphi(M)}\,\mathrm{Re}\Big(\sum_{\xi}\Big(\frac{\tilde{L}'}{\tilde{L}}(1,\xi\chi_K) - \frac{\tilde{L}'}{\tilde{L}}(1,\xi)\Big) - 1\Big),$$

where ξ runs over the Dirichlet characters modulo M, $\xi\chi_K$ is the character modulo Md with the values $\xi(\nu)\chi_K(\nu)$, and $\frac{\tilde{L}'}{\tilde{L}}(s,\chi)$ is the logarithmic derivative of $s \mapsto \tilde{L}(s,\chi)$.

(d) For a real number $x > 0$ put

$$R_{d,M}(x) = \sum_{1 \leq \nu \leq x} \lambda_{d,M}(\nu)\Big(\frac{1}{\nu} - \frac{1}{x}\Big) - \frac{\log x}{\varphi(M)} - \kappa_{d,M}.$$

LEAN lambdaClass · primeError · unit 151 · entireL · unit 106, background

The weight $\lambda_{d,M}(\nu)$ is never negative, and it vanishes unless ν is a power of a prime p with $\chi_K(p) \neq 1$; when $d \equiv 3$ modulo 4, as for every prime d to which the theorems below are applied, these are the primes that do not split in K. The sum in (d) is a smoothed count of such prime powers in the class of 1 modulo M; the term $\log x/\varphi(M) + \kappa_{d,M}$ is its expected value, and $R_{d,M}(x)$ is the *remainder*. That it tends to 0 is a form of the prime number theorem in progressions; under the generalised Riemann hypothesis it is bounded by a constant times $x^{-1/2}$, by the explicit formula, and Theorem 2 is an upper bound of nearly this strength.

Definition 2.6 (the remainder of the data)**.** Let $P = (N_0, d)$ be parameters and D admissible data for P, with scales x, x_1, b; in this definition τ is an infinite place of $E(D)$.

(a) The *nominal weight* of τ is $w_D(\tau) = a(D)/x$ if $\tau \in \mathrm{thick}(D)$, and $w_D(\tau) = a(D)/x_1$ otherwise.

(b) For a real number z,

$$\mathrm{Ask}_D(z, \tau) = \sum_{\nu=1}^{a(D)} \lambda_{d,1}(\nu) \left(\frac{z}{\nu} - w_D((-\nu) \cdot \tau) \right)_+ ,$$

where $(\,\cdot\,)_+$ is the positive part of a real number.

(c) For the prime number d, $\mathrm{cs}(d)$ is Euler's constant minus the real part of the logarithmic derivative of $s \mapsto \tilde{L}(s, \chi_K)$ at $s = 1$. Here χ_K is not principal, so this is the real part of $(L'/L)(1, \chi_K)$.

(d) $\mathrm{Ask}^{\mathrm{main}}(D) = a(D) \cdot (\log a(D) - 1 - \mathrm{cs}(d) - f(D)^{-1} \sum_{\tau'} \log w_D(\tau'))$, where τ' runs over all infinite places of $E(D)$; it is the *expected value* of the sums in (b) for $z = a(D)$.

(e) The *remainder* of D is

$$\mathrm{rem}(D) = \sum_{\tau \in \mathrm{tops}(D)} (\mathrm{Ask}_D(a(D), \tau) - \mathrm{Ask}^{\mathrm{main}}(D)).$$

LEAN `Data.nominalWeight` · `Data.primeSum` · unit 152 · `Data.mainAsk` · `Data.remainder` · unit 151 · `chowlaSelbergConst` · unit 106, background

So $\mathrm{rem}(D)$ compares weighted prime sums at the tops with their expected value. A lemma of unit 151 shows that $-1 - \mathrm{cs}(d) = \kappa_{d,1}$; the overview of this handout writes the expected value with $\kappa_{d,1}$. Input 6 expresses $\mathrm{rem}(D)$ through the remainders of Definition 2.5, and nothing else about Definition 2.6 is used in this note.

Notions of later chapters. Theorem 1 mentions none of the following notions, but its proof passes through them. They are named here with all their arguments; their constructions belong to later chapters and are not needed, because the proof only uses that the conclusion of Input 1 fits the hypothesis of Input 2.

Definition 2.7 (rows, lifts, covolume, index, main amount)**.** Let P be parameters and D admissible data for P, with number of lifts m and rank r.

(a) $\mathrm{Row}(D)$ is a complex vector space, the space of *rows*: certain cusp forms on a unitary group of rank r attached to the field $E(D)$. Its dimension over $\mathbb{C}$ is $\dim \mathrm{Row}(D)$; in the library the dimension of a space that is not finite-dimensional is 0.

(b) The data have *m-fold twists* ϑ: certain characters, defined in later chapters, each with a finite set of primes of $E(D)$ at which it ramifies. Among them is the trivial twist 1, which ramifies at no prime. For an m-fold twist ϑ, $\Theta_{D,\vartheta}$ is a $\mathbb{C}$-linear map from $\mathrm{Row}(D)$ to a space of algebraic modular forms: the composite of m theta lifts, formed with the first m powers of ϑ, restricted to the rows.

(c) A space of algebraic modular forms of the kind in (b) is given by a CM field, a rank, a set of level places, a level subgroup with a character of it, and weights at

the infinite places. For forms $F_1, \dots, F_n$ in one such space and an automorphism σ of the field $\mathbb{C}$, the *squared covolume* $\mathrm{covol}^2_\sigma(F_1, \dots, F_n)$ is the absolute value of the determinant of the matrix of the pairings of the σ-conjugates of $F_1, \dots, F_n$; it is a real number ≥ 0.

(d) For a natural number n, rows $y_1, \dots, y_n$ in $\mathrm{Row}(D)$ and a real number δ, the relation $y_1, \dots, y_n$ have D-index at most δ means: there are real numbers η_ℓ, one for each natural number ℓ, with $\sum_{\ell \in J} \eta_\ell \leq \delta$ for every finite set J of natural numbers, such that for every prime number ℓ, every ℓ-adic place of $\mathbb{C}$ and every m-fold twist ϑ to which ℓ is prime (that is, ℓ is prime to the norms of the primes at which ϑ ramifies), some $n \times n$ matrix over the valuation ring of that place, with determinant of absolute value at least $\exp(-\eta_\ell)$, transforms $y_1, \dots, y_n$ into rows all of whose images under $\Theta_{D,\vartheta}$ are integral at that place.

(e) $h_{\mathrm{main}}(D)$ is a real number, the *main amount*: the product of m, of the rank $r + 1 - m$, and of a real number called the cost of one direction, which is defined from the weights and the prime sums of D.

LEAN `Data.rows` · `Data.rowDim` · unit 140 · `Data.θ` · unit 143 · `LevelPlaces.LevelForm.covolumeSq` · unit 102, background · `Data.IndexLe` · `Data.mainHeight` · unit 151

3 The main inequality

The proof compares two bounds for one quantity. For rows $y_1, \dots, y_n$ as in Input 1 below, let V be the logarithm of a bound for the squared covolumes of their lifts at all automorphisms of $\mathbb{C}$, and δ a bound for their index. Input 1 bounds $V + 2\delta$ from above, Input 2 bounds it from below, and up to errors that are multiples of the budget,

$$h_{\mathrm{main}}(D) \;\leq\; \frac{V + 2\delta}{\dim \mathrm{Row}(D)} \;\leq\; h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D).$$

The inequality between the two ends is Theorem 1. This display is a guide only; it stands in a comment at the head of the file of the unit, in which the authors also list the inputs and the sizes of the errors. The proof follows the Inputs.

Inputs from other units. The following results are taken for granted. They are stated as the dossier of this unit reads them, and each was compared with its Lean text.

Input 1 (Theorems A and B together; unit 151). *Let P be parameters and D admissible data for P, with number of lifts m and third scale b. Then there are a natural number n and rows $y_1, \dots, y_n$ in $\mathrm{Row}(D)$ such that: $y_1, \dots, y_n$ are linearly independent over $\mathbb{C}$; $(1 - 4/b^2) \cdot \dim \mathrm{Row}(D) \le n$; there is a real number δ with $\delta \le 5 \cdot \dim \mathrm{Row}(D) \cdot \log(1 + b^2) \cdot \mathrm{budget}(D)$ such that $y_1, \dots, y_n$ have D-index at most δ; and for every automorphism σ of $\mathbb{C}$,*

$$\mathrm{covol}_\sigma^2(\Theta_{D,1} y_1, \dots, \Theta_{D,1} y_n) \;\le\; \exp(n \cdot (h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \log b \cdot \mathrm{budget}(D))).$$

Input 2 (Theorem C: integral forms are long; unit 151). *Let P be parameters, D admissible data for P with third scale b, n a natural number, $y_1, \dots, y_n$ rows in $\mathrm{Row}(D)$, and δ and V real numbers. Assume that $y_1, \dots, y_n$ are linearly independent over $\mathbb{C}$, that $(1 - 4/b^2) \cdot \dim \mathrm{Row}(D) \le n$, that $y_1, \dots, y_n$ have D-index at most δ, and that $\mathrm{covol}_\sigma^2(\Theta_{D,1} y_1, \dots, \Theta_{D,1} y_n) \le \exp(V)$ for every automorphism σ of $\mathbb{C}$. Then*

$$\dim \mathrm{Row}(D) \cdot \left(h_{\mathrm{main}}(D) - 3 \cdot \log b \cdot \mathrm{budget}(D)\right) \;\le\; V + 2\delta.$$

LEAN `Data.exists_family_covolumeSq_le` · `Data.integral_forms_long`

In the words of the argument, Input 1 puts together Theorem A (short forms: there are integral forms whose lifts are short, with a bound for the index) and Theorem B (enough forms: few translates of them almost span the rows). Input 2 is Theorem C. Three smaller inputs are needed as well.

Input 3 (a crude bound; unit 151). *Let P be parameters and D admissible data for P, with number of lifts m and scales x and b. Then $|h_{\mathrm{main}}(D)| + m \cdot |\mathrm{rem}(D)| \le b^2 \cdot x^{99}$.*

Input 4 (there are rows; unit 148). *Let P be parameters and D admissible data for P. Then $\dim \mathrm{Row}(D) \neq 0$; in particular $\mathrm{Row}(D)$ has finite dimension.*

Input 5 (the constant and the places; unit 152). *Let $P = (N_0, d)$ be parameters. Then $64 \le C(P)$, $N_0 \le C(P)$, $d \le C(P)$ and $\varphi(N_0) \le C(P)$. Let moreover D be admissible data for P. Then N_0 divides $N_1(D)$,*

$$f(D) = \frac{N_1(D)}{N_0} \cdot \varphi(N_0) \qquad \text{and} \qquad \#\mathrm{tops}(D) = \frac{N_1(D)}{N_0}.$$

The formal text states the two equations for every exponent of the tower; they are used here for the exponent of D.

LEAN `Data.abs_mainHeight_add_remainder_le` · `Data.finrank_rows_ne_zero` · `Data.c_ge` · `Parameters.card_infinitePlace_E` · `Parameters.card_placeClass_eq`

Lemma 3.1 (sizes). *Let $P = (N_0, d)$ be parameters and D admissible data for P, with scales x, x_1, b. Then*

(a) $\log b \geq 10^6 \log x_1 \geq 10^{12} \log x$, $\log x \geq 100 \log\log b \geq 10^{14}\, C(P)$ *and* $C(P) \geq 64$*; in particular* $x \geq 2$, $\log b \geq 35$, $x^{99} \leq b$ *and* $\log b \leq x^{1/100}$*;*

(b) $a(D) \geq x\, b$, $f(D) \geq 1$, *and* $\mathrm{budget}(D) \geq b\,(\log b)^3 > 0$*;*

(c) $4 \cdot \log b \cdot \mathrm{budget}(D) + 4\, x^{99} + 10 \cdot \log(1 + b^2) \cdot \mathrm{budget}(D) \;\leq\; (\log b)^2 \cdot \mathrm{budget}(D)$.

Proof. (a) The four inequalities between the logarithms are conditions (i) of Definition 2.3, and $C(P) \geq 64$ is in Input 5. Hence $\log x \geq 64 \cdot 10^{14}$, which gives $x \geq 2$; then $\log b \geq 10^{12} \log x \geq 35$; $99 \log x \leq 10^{12} \log x \leq \log b$ gives $x^{99} \leq b$; and $100 \log\log b \leq \log x$ gives $\log b \leq x^{1/100}$.

(b) The first inequality is the definition of $a(D)$. A number field has an infinite place, so $f(D) \geq 1$. With $x \geq 1$ this gives $\mathrm{budget}(D) = f(D) \cdot a(D) \cdot (\log b)^3 \geq b\,(\log b)^3$, which is positive by (a).

(c) By (a) and (b), $4x^{99} \leq 4b \leq b\,(\log b)^3 \leq \mathrm{budget}(D)$. As $b \geq 1$ and $\log b \geq \log 2$, also $\log(1 + b^2) \leq \log(2b^2) \leq 3 \log b$. So the left side of (c) is at most

$$(4 \log b + 1 + 30 \log b) \cdot \mathrm{budget}(D) \;\leq\; 35\, \log b \cdot \mathrm{budget}(D),$$

and $35 \leq \log b$. □

LEAN in the formal text these comparisons are made by a calculus of sizes of unit 152, `Data.le_of_hasLogBound`; see §8, note 5

Proof of Theorem 1. Let n, $y_1, \dots, y_n$ and δ be as in Input 1, and put

$$h_{\mathrm{A}} = h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \log b \cdot \mathrm{budget}(D).$$

The last property in Input 1 says that the squared covolumes of $\Theta_{D,1} y_1, \dots, \Theta_{D,1} y_n$ are at most $\exp(n\, h_{\mathrm{A}})$. So Input 2 applies to n, $y_1, \dots, y_n$, δ and $V = n\, h_{\mathrm{A}}$, and gives

$$\begin{aligned} \dim \mathrm{Row}(D) \cdot \big(h_{\mathrm{main}}(D) - 3 \cdot \log b \cdot \mathrm{budget}(D)\big) \;&\leq\; n\, h_{\mathrm{A}} + 2\delta \\ &=\; \dim \mathrm{Row}(D) \cdot h_{\mathrm{A}} + \big(\dim \mathrm{Row}(D) - n\big) \cdot (-h_{\mathrm{A}}) + 2\delta. \end{aligned} \tag{1}$$

The two bounds are compared on families of different sizes, n and $\dim \mathrm{Row}(D)$, and the middle term on the right pays for the difference. It is small for the following reasons. By Input 4 the space of rows has finite dimension, so the linearly independent rows $y_1, \dots, y_n$ are at most $\dim \mathrm{Row}(D)$ in number, and with the second property in Input 1,

$$0 \;\leq\; \dim \mathrm{Row}(D) - n \;\leq\; \frac{4}{b^2} \cdot \dim \mathrm{Row}(D).$$

By Lemma 3.1(b), $\log b \cdot \mathrm{budget}(D) > 0$. With Input 3 and $m \geq 0$,

$$-h_{\mathrm{A}} = -h_{\mathrm{main}}(D) + m \cdot \mathrm{rem}(D) - \log b \cdot \mathrm{budget}(D) \;\leq\; |h_{\mathrm{main}}(D)| + m \cdot |\mathrm{rem}(D)| \;\leq\; b^2\, x^{99}.$$

Hence $(\dim \mathrm{Row}(D) - n) \cdot (-h_{\mathrm{A}}) \leq 4\, x^{99} \cdot \dim \mathrm{Row}(D)$. The bound for δ in Input 1 gives $2\delta \leq 10 \cdot \log(1 + b^2) \cdot \mathrm{budget}(D) \cdot \dim \mathrm{Row}(D)$. Putting these into (1),

$$h_{\mathrm{main}}(D) - 3 \cdot \log b \cdot \mathrm{budget}(D) \;\leq\; h_{\mathrm{A}} + 4\, x^{99} + 10 \cdot \log(1 + b^2) \cdot \mathrm{budget}(D),$$

after division by $\dim \mathrm{Row}(D)$, which is positive by Input 4. Inserting the definition of h_{A}, the main amount $h_{\mathrm{main}}(D)$ cancels, and

$$\begin{aligned} m \cdot \mathrm{rem}(D) \;&\leq\; 4 \cdot \log b \cdot \mathrm{budget}(D) + 4\, x^{99} + 10 \cdot \log(1 + b^2) \cdot \mathrm{budget}(D) \\ &\leq\; (\log b)^2 \cdot \mathrm{budget}(D), \end{aligned}$$

the last step by Lemma 3.1(c). □

LEAN star_inequality

The three terms of the error have separate sources: $4 \cdot \log b \cdot \mathrm{budget}(D)$ is the error of length in Input 1 and the error of covolume in Input 2, $4x^{99}$ pays for the dimensions that the rows do not span, and the last term is the index. All three are far below $(\log b)^2 \cdot \mathrm{budget}(D)$; the exponents 99 and 2 are slack.

4 The bound for the primes

Definition 4.1 (polar functions)**.** Let $\mathcal{E}\colon \mathbb{R} \to \mathbb{R}$ and $\omega\colon \mathbb{C} \to \mathbb{C}$ be functions. We say that $\mathcal{E}$ is polar with residue function ω, and write $\mathrm{Polar}(\mathcal{E}, \omega)$, if $\mathcal{E}$ is measurable and there is a function $\Phi\colon \mathbb{C} \to \mathbb{C}$, meromorphic on $\mathbb{C}$ and defined at every point (at a pole its value is arbitrary), such that: the function $v \mapsto |\mathcal{E}(v)| \exp(-v)$ is bounded on $v \geq 0$; $\Phi(s) = \int_0^\infty \mathcal{E}(v) \exp((1-s)v)\, dv$ for $\mathrm{Re}\, s > 2$; the function $s \mapsto (s-1)\Phi(s)$, whose value at $s = 1$ is 0 whatever $\Phi(1)$ is, is analytic at every point of the closed half-plane $\mathrm{Re}\, s \geq 1$; and for every complex number ρ with $\mathrm{Re}\, \rho > 0$, $(s-\rho)\Phi(s) \to \omega(\rho)$ as $s \to \rho$, $s \neq \rho$.

LEAN IsPolar · unit 107, background

So Φ continues the Laplace transform of $\mathcal{E}$. The third condition is to be read with its clause on the value at 1: it says that Φ is analytic at every point $s \neq 1$ of $\mathrm{Re}\, s \geq 1$, and that near $s = 1$ it is the quotient by $s - 1$ of an analytic function that vanishes at 1. So the singularity at 1 is removable, Φ has no pole on $\mathrm{Re}\, s \geq 1$, and $\omega(\rho) = 0$ for $\mathrm{Re}\, \rho \geq 1$. The clause cannot be dropped. Without it the constant function 1, whose transform is $1/(s-1)$, would be polar, and Input 9 below would be false for the constant functions 1 and 0: it would give $1 \leq \exp(-v_0)$ for large v_0. In the half-plane $\mathrm{Re}\, s > 0$ the poles of Φ are at most simple, with residue $\omega(\rho)$ at ρ. The definition, with a remark that derives these consequences, is also in Chapter II of this handout, the note *From a one-sided bound for primes to a zero-free half-plane*, in the same letters.

Inputs from other units.

Input 6 (the remainder of the data, through the remainders of the prime sums; unit 151). *Let $P = (N_0, d)$ be parameters and D admissible data for P, with first scale x and second scale x_1. Then*

$$\mathrm{rem}(D) = a(D) \cdot \Big(\#\mathrm{thick}(D) \cdot (R_{d,N_0}(x) - R_{d,N_0}(x_1)) + \#\mathrm{tops}(D) \cdot R_{d,1}(x_1) \Big).$$

Input 7 (data exist; unit 152). *Let $P = (N_0, d)$ be parameters and ε a real number with $0 < \varepsilon/6$ and $\varepsilon < \frac{1}{100}$. Then for every sufficiently large real number x there are admissible data D for P with first scale x, whose second scale x_1 and third scale b satisfy*

$$\log x_1 = x^{\varepsilon/6}, \qquad (10^6 \log x)^2 \leq \log x_1,$$
$$\log\log b = \varepsilon \log x, \qquad \frac{N_1(D)/N_0}{\log b} \leq \#\mathrm{thick}(D).$$

LEAN Data.remainder_eq · exists_data

Input 6 is where the prime sums of Definition 2.6 become the remainders of Definition 2.5: as τ runs over the tops, the places $(-\nu)\cdot\tau$ run over the classes $\equiv -\nu$ modulo N_0, which contain the thick places exactly when $\nu \equiv 1$ modulo N_0. So the thick places see the weight $\lambda_{d,N_0}(\nu)$ at the first scale, every place sees $\lambda_{d,1}(\nu)$ at the second scale, and the main terms are the expected values. Input 7 provides the data, and the next two inputs make it possible to move the second scale.

Input 8 (the remainders are polar; unit 151). *Let d be a prime number and $M \geq 1$ an integer such that $d \equiv 7$ modulo 8 and M is prime to d. For a complex number $\rho \neq 0, 1$ let*

$$\mathrm{res}_{d,M}(\rho) = \frac{1}{\varphi(M)\,\rho\,(1-\rho)} \sum_{\xi} (\mathrm{ord}_\rho\, \tilde{L}(\,\cdot\,,\xi) - \mathrm{ord}_\rho\, \tilde{L}(\,\cdot\,,\xi\chi_K)),$$

where ξ runs over the Dirichlet characters modulo M, $\xi\chi_K$ is as in Definition 2.5, and ord_ρ is the order of vanishing at ρ of an entire function that is not zero; and let $\mathrm{res}_{d,M}(0) = \mathrm{res}_{d,M}(1) = 0$. Then, as a function of the real variable v, $v \mapsto R_{d,M}(\exp(v))$ is polar with residue function $\rho \mapsto \mathrm{res}_{d,M}(\rho)$.

Input 9 (a good point in every long window; unit 151). *Let $\mathcal{E}_1$, $\mathcal{E}_2$ be functions from $\mathbb{R}$ to $\mathbb{R}$ and ω_1, ω_2 functions from $\mathbb{C}$ to $\mathbb{C}$ such that $\mathcal{E}_1$ is polar with residue function ω_1 and $\mathcal{E}_2$ is polar with residue function ω_2. Then for every sufficiently large real number v_0 and every real number X with $0 \leq X \leq \exp(v_0)$ there is a real number v_1 with $v_0 \leq v_1 \leq v_0^2$ and*

$$\mathcal{E}_1(v_1) - X \cdot \mathcal{E}_2(v_1) \;\leq\; \exp(-v_0).$$

LEAN `isPolar_primeError` · `IsPolar.exists_window_sub_mul_le`

In Input 8 the formal text gives the residue function by the one formula, for every complex ρ; a quotient by 0 is 0 in Lean, which is the value at $\rho = 0$ and $\rho = 1$ stated above. The values of the residue function play no role in this note, which uses only that the remainders are polar.

Lemma 4.2 (the parameters). *Let $P = (N_0, d)$ be parameters. Then $d \equiv 7$ modulo 8, and N_0 is prime to d.*

Proof. As 16 divides 18480, which divides N_0, and N_0 divides $2(d+1)$, the number 8 divides $d+1$. Let p be a prime that divides N_0. Then p divides $2(d+1)$. If $p = d$, then d divides 2, which is impossible since $d \equiv 7$ modulo 8. Hence no prime divides both N_0 and d. □

LEAN `Parameters.instHeegD` · `Parameters.coprime_N₁_d` · unit 152; the proof here is direct

Lemma 4.3 (moving the second scale). *Let P be parameters, D admissible data for P with scales x, x_1, b, and v_1 a real number with $10^6 \log x \leq v_1 \leq \log x_1$. Let D' be the record whose second scale is $\exp(v_1)$ and whose other components are those of D. Then D' are admissible data for P. Moreover $N_1(D') = N_1(D)$, $E(D') = E(D)$, $\mathrm{thick}(D') = \mathrm{thick}(D)$, $\mathrm{tops}(D') = \mathrm{tops}(D)$, $f(D') = f(D)$, $a(D') = a(D)$ and $\mathrm{budget}(D') = \mathrm{budget}(D)$.*

Proof. Only the conditions (i) of Definition 2.3 mention $\log x_1$, and of these the last three. For D' the first of the three is the lower bound for v_1. Since $0 < v_1 \le \log x_1$, the other two follow from those for D: $10^6 v_1 \le 10^6 \log x_1 \le \log b$ and $6 \log v_1 \le 6 \log\log x_1 \le \log\log b$. The quantities listed do not involve the second scale. □

Proof of Theorem 2. By Lemma 4.2, $d \equiv 7$ modulo 8 and N_0 is prime to d; also 1 is prime to d. So Input 8 applies with $M = N_0$ and with $M = 1$: the functions $\mathcal{E}_1(v) = R_{d,N_0}(\exp(v))$ and $\mathcal{E}_2(v) = R_{d,1}(\exp(v))$ are polar, and Input 9 applies to them. Let x be so large that Input 7 gives admissible data D for P with first scale x and the properties stated there, and that $v_0 = 10^6 \log x$ is large enough for the conclusion of Input 9. Let x_1 and b be the second and third scale of D and m its number of lifts. We show that $R_{d,N_0}(x) \le x^{8\varepsilon+\frac{1}{2}-1}$.

The window. Put $X = (N_1(D)/N_0)/\#\mathrm{thick}(D)$. The last property in Input 7, with $N_1(D)/N_0 \ge 1$ and $\log b > 0$, shows that $\#\mathrm{thick}(D) > 0$ and that $0 \le X \le \log b$. By Lemma 3.1(a), $\log b \le x^{1/100} \le \exp(v_0)$. So Input 9 gives a real number v_1 with

$$v_0 \le v_1 \le v_0^2 \qquad \text{and} \qquad R_{d,N_0}(\exp(v_1)) - X \cdot R_{d,1}(\exp(v_1)) \;\le\; \exp(-v_0) = x^{-10^6}. \tag{2}$$

The new data. By Input 7, $v_0^2 \le \log x_1$. So $10^6 \log x = v_0 \le v_1 \le \log x_1$, and Lemma 4.3 gives admissible data D' for P with second scale $\exp(v_1)$, which agree with D in the first and third scale, the number of lifts, the thick places, the tops, and in $f(D)$, $a(D)$ and the budget.

The identity. Input 6 for D', with $\#\mathrm{tops}(D) = N_1(D)/N_0$ from Input 5, reads

$$\mathrm{rem}(D') = a(D) \cdot \Big(\#\mathrm{thick}(D) \cdot (R_{d,N_0}(x) - R_{d,N_0}(\exp(v_1))) + \frac{N_1(D)}{N_0} \cdot R_{d,1}(\exp(v_1)) \Big).$$

Solving for $R_{d,N_0}(x)$, which is possible because $a(D)$ and $\#\mathrm{thick}(D)$ are positive,

$$R_{d,N_0}(x) = \frac{m \cdot \mathrm{rem}(D')}{m \cdot a(D) \cdot \#\mathrm{thick}(D)} + \Big(R_{d,N_0}(\exp(v_1)) - X \cdot R_{d,1}(\exp(v_1)) \Big). \tag{3}$$

The two bounds. The bracket in (3) is at most x^{-10^6} by (2). Theorem 1 for D' gives $m \cdot \mathrm{rem}(D') \le (\log b)^2 \cdot \mathrm{budget}(D) = f(D) \cdot a(D) \cdot (\log b)^5$. So the first term of (3) is at most

$$\frac{f(D) \cdot (\log b)^5}{m \cdot \#\mathrm{thick}(D)} \;\le\; \frac{\varphi(N_0)\,(\log b)^6}{\sqrt{x}} \;=\; \varphi(N_0)\, x^{6\varepsilon-\frac{1}{2}},$$

where the inequality uses the value $f(D) = (N_1(D)/N_0) \cdot \varphi(N_0)$ from Input 5, the bound $N_1(D)/N_0 \le \log b \cdot \#\mathrm{thick}(D)$ of Input 7, and $m \ge \sqrt{x}$; the equality is $\log b = x^{\varepsilon}$, again from Input 7.

The sizes. By Input 5 and the conditions (i), $\varphi(N_0) \le C(P) \le 10^{-12} \log\log b = 10^{-12}\, \varepsilon \log x$, and $\varepsilon \log x \le \frac{1}{2} \exp(2\varepsilon \log x) = \frac{1}{2} x^{2\varepsilon}$. So the first term is at most $\frac{1}{2} x^{8\varepsilon-\frac{1}{2}}$. As $x \ge 2$ by Lemma 3.1(a) and $\varepsilon > 0$, $x^{-10^6} \le \frac{1}{2} x^{8\varepsilon-\frac{1}{2}}$. Therefore $R_{d,N_0}(x) \le x^{8\varepsilon-\frac{1}{2}} = x^{8\varepsilon+\frac{1}{2}-1}$. □

LEAN `eventually_primeError_le_rpow`

The saving $x^{-1/2}$ comes from the division by m: Theorem 1 bounds $m \cdot \mathrm{rem}(D')$, not $\mathrm{rem}(D')$, by a quantity of the size of the trivial bound for the remainder, and m is about $\sqrt{x}$. The number of lifts is in this sense the source of the exponent $\frac{1}{2}$.

5 The zero-free half-plane

Input from another unit.

Input 10 (the one-sided criterion, after Landau; unit 151). *Let $M \geq 1$ be an integer, c an element of $\mathbb{Z}/M$ and β a real number, with $\frac{1}{2} < \beta$ and c a unit of the ring $\mathbb{Z}/M$. Assume that for every prime number d whose class modulo M is c: $d \equiv 7$ modulo 8, M is prime to d, and $R_{d,M}(x) \leq x^{\beta-1}$ for every sufficiently large real number x. Then for every complex number ρ with $\beta < \operatorname{Re}\rho$ and every Dirichlet character χ modulo M, $\tilde{L}(\rho, \chi) \neq 0$.*

LEAN `entireL_ne_zero_of_primeError_le`

The criterion is read in the note on the endgame. Its proof takes one suitable prime d of the class; by Input 8 the Laplace transform of $v \mapsto R_{d,M}(\exp(v))$ has a pole at every zero of an L-function modulo M that is not cancelled by a zero of a twisted L-function, and Landau's theorem on integrals of functions of one sign excludes poles to the right of β once the one-sided bound holds.

In the proof of Theorem 3 two facts of the library about characters are used. Let $M \geq 1$ be an integer, χ a Dirichlet character modulo M, and M' a multiple of M with $M' \geq 1$; let χ' be the character modulo M' induced by χ. First, χ' is principal if and only if χ is. Second, for every complex number s such that χ is not principal or $s \neq 1$,

$$L(s, \chi') = L(s, \chi) \cdot \prod_{p \mid M'} (1 - \chi(p)\, p^{-s}), \tag{4}$$

the product over the primes p dividing M'.

Proof of Theorem 3. Let $M \geq 1$ be an integer, χ a Dirichlet character modulo M and s a complex number with $\operatorname{Re} s > \frac{1}{2}$, such that χ is not principal or $s \neq 1$. Assume that $L(s, \chi) = 0$; we derive a contradiction. Put

$$\varepsilon = \frac{\min(\operatorname{Re} s, 1) - \frac{1}{2}}{51}, \qquad \beta = 8\varepsilon + \tfrac{1}{2}.$$

Then $0 < \varepsilon \leq \frac{1}{102} < \frac{1}{100}$ and $\frac{1}{2} < \beta$, and $\beta < \operatorname{Re} s$ because $8\varepsilon < \min(\operatorname{Re} s, 1) - \frac{1}{2}$.

The modulus. Let $N_0 = 18480\, M$, and let χ' be the character modulo N_0 induced by χ. Then $\tilde{L}(s, \chi') = 0$. Indeed, if χ is not principal, then χ' is not principal, and $\tilde{L}(s, \chi') = L(s, \chi') = 0$ by (4). If χ is principal, then χ' is principal and $s \neq 1$, so $\tilde{L}(s, \chi') = (s-1)L(s, \chi') = 0$, again by (4).

The class. Let c be the class of $9240\, M - 1$ modulo N_0, that is, of $N_0/2 - 1$. It is a unit, because $(9240\, M - 1)^2 = 18480\, M \cdot (4620\, M - 1) + 1$. Let d be a prime number in the class c. Then $P = (N_0, d)$ are parameters: 18480 divides N_0; and $d + 1 \equiv N_0/2$ modulo N_0, so N_0 divides $2(d+1)$ and does not divide $d + 1$. By Lemma 4.2, $d \equiv 7$ modulo 8 and N_0 is prime to d. By Theorem 2 for P and ε, $R_{d,N_0}(x) \leq x^{8\varepsilon + \frac{1}{2} - 1} = x^{\beta - 1}$ for every sufficiently large real number x.

The criterion. So the hypotheses of Input 10 hold for the modulus N_0, the class c and β. As $\beta < \operatorname{Re} s$, it gives $\tilde{L}(s, \chi') \neq 0$. This contradicts the first step. □

LEAN `New.grh`

Theorem 2 is used here for every prime d of one residue class modulo N_0, with one ε that depends on s; how large x has to be may depend on d. The modulus $18480\,M$ is chosen so that it can be the first component of parameters, and the passage from M to it costs nothing, because (4) is needed only in one direction: a zero of $L(\,\cdot\,,\chi)$ is a zero of $L(\,\cdot\,,\chi')$.

6 The critical line

Input from another unit.

Input 11 (symmetry of the zeros; unit 106, background). *Let $M \geq 1$ be an integer, χ a Dirichlet character modulo M, and s a complex number with $\operatorname{Re} s \neq 0$, $s \neq 1$ and $L(s,\chi) = 0$. Then $\Gamma_\chi(s) = 0$ or $L(1-s,\chi^{-1}) = 0$.*

LEAN `LFunction_one_sub_eq_zero`

Here Γ_χ is the gamma factor of χ in the library: $\Gamma_\chi(s) = \Gamma_{\mathbb{R}}(s)$ if $\chi(-1) = 1$ and $\Gamma_\chi(s) = \Gamma_{\mathbb{R}}(s+1)$ otherwise, where $\Gamma_{\mathbb{R}}(s) = \pi^{-s/2}\,\Gamma(s/2)$. The library's function Γ takes the value 0 at its poles $0, -1, -2, \dots$, so $\Gamma_\chi(s) = 0$ says that s is a pole of the gamma factor. Input 11 is the functional equation of the completed L-function, in the form that it takes for the zeros and for characters that need not be primitive. It is a classical result; the catalogue of quoted results of this write-up records it with its reference still to be confirmed. The library also provides the following facts, in which ζ^* is its completed zeta function.

(Z1) For the Dirichlet character χ modulo 1, $L(s,\chi) = \zeta(s)$ for every complex number s.

(Z2) $\zeta(0) = -\frac{1}{2}$.

(Z3) For $s \neq 0$, $\zeta(s) = \zeta^*(s)/\Gamma_{\mathbb{R}}(s)$, where a quotient by 0 is 0.

(Z4) $\zeta^*(1-s) = \zeta^*(s)$ for every complex number s.

(Z5) $\Gamma_{\mathbb{R}}(s) = 0$ if and only if $s = -2n$ for a natural number n; in particular $\Gamma_{\mathbb{R}}(s) \neq 0$ when $\operatorname{Re} s > 0$.

Proof of Theorem 4. Assume the half-plane statement. Let $M \geq 1$ be an integer, χ a Dirichlet character modulo M and s a complex number with $0 < \operatorname{Re} s < 1$ and $L(s,\chi) = 0$. If $\operatorname{Re} s > \frac{1}{2}$, the half-plane statement gives $L(s,\chi) \neq 0$, since $s \neq 1$; so $\operatorname{Re} s \leq \frac{1}{2}$. Suppose that $\operatorname{Re} s < \frac{1}{2}$. Input 11 applies, because $\operatorname{Re} s \neq 0$ and $s \neq 1$. The gamma factor does not vanish at s, by (Z5): $\operatorname{Re} s > 0$ and $\operatorname{Re}(s+1) > 0$. Hence $L(1-s,\chi^{-1}) = 0$. But $\operatorname{Re}(1-s) > \frac{1}{2}$ and $1-s \neq 1$, so the half-plane statement for the character χ^{-1} gives $L(1-s,\chi^{-1}) \neq 0$, a contradiction. Therefore $\operatorname{Re} s = \frac{1}{2}$. □

LEAN `New.zeros_on_line`

Proof of Theorem 5. Assume the half-plane statement, and let s be a complex number with $\zeta(s) = 0$, not of the form $-2(n+1)$ with n a natural number, and with $s \neq 1$. By (Z1), the half-plane statement for $M = 1$ says: $\zeta(\rho) \neq 0$ for every complex number ρ with $\operatorname{Re}\rho > \frac{1}{2}$ and $\rho \neq 1$. With $\rho = s$ this gives $\operatorname{Re} s \leq \frac{1}{2}$.

By (Z2), $s \neq 0$. So s is not of the form $-2n$ with n a natural number, and $\Gamma_{\mathbb{R}}(s) \neq 0$ by (Z5). By (Z3), $0 = \zeta(s) = \zeta^*(s)/\Gamma_{\mathbb{R}}(s)$, hence $\zeta^*(s) = 0$, and $\zeta^*(1-s) = 0$ by (Z4). As $1-s \neq 0$, (Z3) gives $\zeta(1-s) = \zeta^*(1-s)/\Gamma_{\mathbb{R}}(1-s) = 0$. Now $1-s \neq 1$;

so if $\operatorname{Re}(1-s) > \frac{1}{2}$, the half-plane statement with $\rho = 1-s$ would give $\zeta(1-s) \neq 0$. Hence $\operatorname{Re}(1-s) \leq \frac{1}{2}$, that is, $\operatorname{Re} s \geq \frac{1}{2}$, and so $\operatorname{Re} s = \frac{1}{2}$. □

LEAN `New.zeta_zeros_on_line`

7 Where the results are used

Theorem 1 is used only in the proof of Theorem 2, and Theorem 2 only in the proof of Theorem 3. Theorems 3, 4 and 5 are the three inputs of the unit that holds the five final theorems: the third final theorem is Theorem 3, the fourth is Theorem 4 applied to Theorem 3, and the first two are Theorem 5 applied to Theorem 3. Nothing else in the artifact uses this unit.

8 Notes on the formal text

1. *Names.* The authors call Theorem 1 the inequality ($\star$) and Theorem 2 the one-sided bound. In the formal text the parameters and the data of Theorem 1 are implicit arguments.

2. *Theorem 2.* The two inequalities for ε form one hypothesis, a conjunction, written $0 < \varepsilon/6$ and $\varepsilon < \frac{1}{100}$; the exponent is written $8\varepsilon + 2^{-1} - 1$. "For every sufficiently large real number" renders Lean's "eventually, as the number tends to infinity". In Definition 2.5(d) the formal definition is made for every real x; only large x matters. The constant $\kappa_{d,M}$ is the real part of the value at 1 of a function that the formal text defines for every complex argument.

3. *The record of the data.* The formal record stores the three logarithms, not the scales, and its conditions (i) are written with the library's logarithm, which is defined for all real numbers as the logarithm of the absolute value. The conditions force $\log x$, $\log x_1$ and $\log b$ to be positive (Lemma 3.1(a) is proved from them in the order in which (i) lists them), so the iterated logarithms are the usual ones. The record has one more component, a natural number that the formal text calls the exponent; a condition makes it equal to $22 \log_2 m$. This write-up keeps the formal text's letter for it free for the complex variable and does not name it: the degree of the tower, a function of the exponent in the formal text, is $N_1(D)/N_0$ here, and the conditions on the exponent are those on $22 \log_2 m$ in (ii).

4. *Input 7 is not used in full.* The proof of Theorem 2 does not use the equation $\log x_1 = x^{\varepsilon/6}$; it uses the inequality $(10^6 \log x)^2 \leq \log x_1$, which leaves room for the window.

5. *The comparisons of sizes.* The formal text does not carry out the estimates of Lemma 3.1(c) and of the last step of the proof of Theorem 2. It proves them by a calculus of unit 152: every quantity built from the data carries an upper or a lower bound that is the exponential of a real number, found by Lean's search for instances, and an inequality between two quantities is reduced to an inequality between two such exponents, which a decision procedure proves from the conditions (i). The estimates in this note are explicit, and they are mine; they use the same facts, which are the conditions (i) and (ii), the definition of $a(D)$ and Input 5. Of Input 5 the formal proofs of this unit cite by name only the number of the tops; the bounds for $C(P)$ and the number of the infinite places enter through the calculus. All three statements were read in the Lean text.

6. *The new data.* Lemma 4.3 is not a declaration. The formal text builds D' inside the proof of Theorem 2 by replacing one component, and proves the conditions (i) on the spot.
7. *Lemma 4.2.* The formal text cites two declarations of unit 152. The second says that the order of the roots of unity, for every exponent of the tower, is prime to d, and deduces this from the fact that χ_K takes the value 1 at every prime dividing that order; the formal proofs of Theorems 2 and 3 use it for the exponent 0 and keep the factor N_0. The proof given here is direct.
8. *The constant* 51. In the proof of Theorem 3 the formal text defines ε with the same divisor 51; any divisor larger than 50 would do.
9. *Theorems 4 and 5.* Each of the two formal proofs is one call of an automatic procedure that is given the facts used above: Input 11 and (Z5) for Theorem 4, (Z1) to (Z5) for Theorem 5. The case distinctions written out here are what that procedure has to find. They depend on the library's conventions, which are part of the statements (Z3) and (Z5): a quotient by 0 is 0, and Γ is 0 at its poles.
10. *What the unit does not use.* Every declaration of the unit is used by the five final theorems.

How this note was written. From the structured proofs of the unit: the program check of the dossier covered 27 leaf steps of 5 proofs and compared the quotations of the imported declarations with the source. In the Lean text I read the whole file of the unit, with the long comment at its head in which the authors list the inputs, the scales and the errors. I read the statements of all eleven Inputs, and the definitions behind every notion of §2: the parameters, the tower, the field, its places and their classes, every field of the record of admissible data, the derived quantities, the weight, the remainder of the prime sum with the functions it is built from, the prime sums and the remainder of the data, the polar functions, and the lines that define the rows, the lifts, the index, the squared covolume and the main amount. I read the proof of Input 11, which is short, and did not study the proofs of the other Inputs. In the library, at the pinned commit of its public repository, I read the statements listed in the second table of Appendix A. The letters and the forms of the notations are those of the overview of this handout. The proofs follow the structured proofs, with these differences, which are mine: Lemma 3.1 and the estimates at the end of the proof of Theorem 2 replace the calculus of sizes; Lemma 4.2 is proved directly; the proofs of Theorems 4 and 5 are written out; and the explanations between the proofs are mine.

The five statements of the unit as they are written in the artifact. Theorems 1 to 5:

```
lemma star_inequality {P} {D : Data P} : D.m * D.remainder ≤ D.logB ^ 2 * D.budget

lemma eventually_primeError_le_rpow (P : Parameters) {ε : ℝ} (h : 0 < ε / 6 ∧ ε < 1 / 100) :
    ∀ᶠ x in atTop, primeError P.d P.N₀ x ≤ x ^ (8 * ε + 2⁻¹ - 1)

lemma New.grh : DirichletLNonvanishingRightOfHalf

lemma New.zeros_on_line (h : DirichletLNonvanishingRightOfHalf) : DirichletLZerosOnLine

lemma New.zeta_zeros_on_line (h : DirichletLNonvanishingRightOfHalf) :
    RiemannZetaZerosOnLine
```

Inputs 1 and 2:

```
lemma Data.exists_family_covolumeSq_le (D : Data P) : ∃ n, ∃ y : Fin n → _, LinearIndependent ℂ y ∧
    (1 - 4 / D.b ^ 2) * D.rowDim ≤ n ∧
  (∃ δ ≤ 5 * D.rowDim * log (1 + D.b ^ 2) * D.budget, D.IndexLe y δ) ∧ ∀ σ,
  covolumeSq (D.θ 1 ∘ y) σ ≤ exp (n * (D.mainHeight - D.m * D.remainder + D.logB * D.budget))

lemma Data.integral_forms_long : D.rowDim * (D.mainHeight - 3 * (D.logB * D.budget)) ≤
  V + 2 * δ
```

Input 2 is stated in a part of its file where the rows, the two real numbers and its four hypotheses are declared beforehand; the hypotheses are the arguments `i`, `hn`, `I` and `hV`.

Legend. For data `D` of the formal text: `D.logX`, `D.logX₁`, `D.logB` are $\log x$, $\log x_1$, $\log b$, and `D.x`, `D.x₁`, `D.b` are the scales; `D.m` and `D.r` are m and r; `D.s` is the exponent $22 \log_2 m$, and `towerDeg D.s` is $N_1(D)/N_0$; `D.thick` is thick(D); `D.Φ` is the set of infinite places of $E(D)$; `P.N₀`, `P.d` and `P.c` are N_0, d and $C(P)$. The class of a place is given by `Parameters.placeMulEquiv` and, modulo a divisor, by `Parameters.placeClass`; the place $\nu \cdot \tau$ is the product of `D.placeOfInt v` and τ. The character $\xi\chi_K$ is `quadTwist ξ d`, and χ_K is `chiK d`; $\kappa_{d,M}$ is the real part of `logDerivMean d M 1`. In the formal proofs of this unit the modulus of Theorem 3 is `q` and the complex number is `ρ`; in the file of the statements they are `N` and `s`. The window of Input 9 is written there with `t`, `υ`, `E` and `E'` for v_0, v_1, $\mathcal{E}_1$ and $\mathcal{E}_2$, and the class of Input 10 with `a` for c. In the proof of Theorem 1 the formal text writes `d` for $\dim \mathrm{Row}(D)$, `L` for $\log b \cdot \mathrm{budget}(D)$ and `h` for h_{A}.

The facts of the library. The library is Mathlib at the commit that the artifact pins in its manifest.

Notation

$P = (N_0, d)$ parameters: 18480 divides N_0, d is a prime $\equiv N_0/2 - 1$ modulo N_0

K, χ_K the field $\mathbb{Q}(\sqrt{-d})$; the quadratic character of $\mathbb{Z}/d$, the Legendre symbol for odd d

D, D' admissible data for P

x, x_1, b the three scales of D; x also a real variable

m, r the number of lifts and the rank of D

$C(P)$ a constant attached to P

$N_1(D)$, $E(D)$ the order of the roots of unity; the field they generate over K

τ, τ', $\mathrm{cl}_D(\tau)$ infinite places of $E(D)$; the class in $(\mathbb{Z}/N_1(D))^\times$

thick(D), tops(D) the thick places; the tops

$f(D)$, $a(D)$ the number of infinite places of $E(D)$; the least multiple of $N_1(D)$ that is $\geq xb$

budget(D) the budget $f(D) \cdot a(D) \cdot (\log b)^3$

M, M' moduli, integers ≥ 1

ν, n, p an integer; a natural number; a prime number

Λ, φ von Mangoldt's function; Euler's function

$\lambda_{d,M}(\nu)$ the weight $\Lambda(\nu)(1-\chi_K(\nu))$ on $\nu \equiv 1$ modulo M

χ, χ', ξ Dirichlet characters; χ' induced by χ

s, ρ complex numbers

$L(s,\chi)$, $\tilde{L}(s,\chi)$ the L-function; the entire function equal to it, or to $(s-1)L(s,\chi)$ for principal χ

ζ, ζ^* the zeta function; the completed zeta function

Γ, $\Gamma_{\mathbb{R}}$, Γ_χ, π the gamma function; $\pi^{-s/2}\Gamma(s/2)$; the gamma factor of χ

$\kappa_{d,M}$, $R_{d,M}(x)$ a constant; the remainder of the weighted prime sum

$w_D(\tau)$, z the nominal weight; a real number

$\mathrm{Ask}_D(z,\tau)$, $\mathrm{Ask}^{\mathrm{main}}(D)$ a weighted prime sum; its expected value

$\mathrm{cs}(d)$ Euler's constant minus $\mathrm{Re}(L'/L)(1,\chi_K)$

$\mathrm{rem}(D)$ the remainder of the data D

$\mathrm{Row}(D)$, $\dim \mathrm{Row}(D)$ the space of rows; its dimension

ϑ, $\Theta_{D,\vartheta}$ an m-fold twist; the composite of the lifts

$F_1, \dots, F_n$, σ algebraic modular forms; an automorphism of $\mathbb{C}$

$\mathrm{covol}^2_\sigma(F_1, \dots, F_n)$ the squared covolume

$y_1, \dots, y_n$ rows

δ, V real numbers: a bound for the index, the logarithm of a bound for the covolume

ℓ, η_ℓ, J a natural number, mostly a prime; real numbers indexed by ℓ; a finite set of natural numbers (in the definition of the index)

$h_{\mathrm{main}}(D)$, h_{A} the main amount; the bound of Input 1 for one row, $h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \log b \cdot \mathrm{budget}(D)$

ε, β real numbers; $\beta = 8\varepsilon + \frac{1}{2}$ in §5

$\mathcal{E}$, $\mathcal{E}_1$, $\mathcal{E}_2$; ω, ω_1, ω_2; Φ functions $\mathbb{R} \to \mathbb{R}$; functions $\mathbb{C} \to \mathbb{C}$, residue functions; the transform, in the definition of polar functions

$\mathrm{res}_{d,M}(\rho)$, ord_ρ the residue of Input 8; the order of vanishing at ρ

v, v_0, v_1, X real numbers in the window of Input 9

c a class modulo M

Chapter II

From a one-sided bound for primes to a zero-free half-plane

- **The endgame: the weighted prime sum and its remainder, the one-sided criterion (Landau), the choice of the second scale, and the statements and assembly of Theorems A, B and C** (unit 151)

  read: note built, structured proofs checked. 29 declarations, 149 proof lines.

READBACK NOTE · CHAPTER II

From a one-sided bound for primes to a zero-free half-plane

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The unit read here closes the argument of the formal proof, and it has two parts. Part I is analytic number theory. For a prime $d \equiv 7 \pmod 8$ and a modulus M prime to d it studies the remainder $R_{d,M}(x)$ of a weighted sum over the prime powers $\equiv 1 \pmod M$ that sees only the primes not split in $\mathbb{Q}(\sqrt{-d})$. The Laplace transform of $v \mapsto R_{d,M}(\mathrm{e}^v)$ is meromorphic. In the half-plane $\operatorname{Re} s > 0$ its poles lie at zeros of the Dirichlet L-functions modulo M and of their twists by the Legendre symbol modulo d, and its residue at such a point ρ is $1/(\varphi(M)\rho(1-\rho))$ times the difference of two sums of orders of vanishing at ρ: that of the L-functions modulo M minus that of their twists; here φ is Euler's function (Theorem 1). By Landau's lemma, a one-sided bound $R_{d,M}(x) \le x^{\beta-1}$, valid for all primes d of one residue class, then forces $L(s,\chi) \neq 0$ for $\operatorname{Re} s > \beta$ and every character χ modulo M (Theorem 2); a companion finds, in every window $[v_0, v_0^2]$, a point where a combination of two such remainders is at most e^{-v_0} (Theorem 3). Part II belongs to the geometric side of the proof: it writes the remainder of the data as a combination of the $R_{d,M}(x)$ (Theorem 4), and it carries out the last steps of the three statements on theta lifts that the authors call Theorems A, B and C.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof of the Riemann hypothesis and of its generalisation to Dirichlet L-functions. Its authors report that it compiles and that the kernel of Lean accepts the final theorems from the three standard axioms; a replay by the owner of this write-up is recorded with the write-up, not here, and nothing was compiled for this note. No mathematician has read the argument through, so the headline is a *claim*, and this note does not say that the Riemann hypothesis is proved. It says what one unit of the formal text asserts and how it argues. The note treats 29 of the 29 declarations of the unit. *Proved here in full*: everything in Part I (Theorems 1 to 3 and the lemmas), from seven results of the background library that are quoted with their statements (Inputs 1 to 7: among them Landau's lemma, the non-vanishing of L-functions on $\operatorname{Re} s \ge 1$, and a zero-free box for quadratic twists); and Theorem 4, from the description of the data. *Deduced here from inputs that carry the substance*: Theorems A, B and C, whose proofs in this unit are short deductions from results of other units, stated as Inputs 8 to 25 with the unit that owns each. Every statement of the unit, and every quoted statement of the background library, was compared by the writer with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 44 declarations.

1 The statements of Part I

The objects first, in one paragraph; the definitions are in §2. Let d be a prime number and $M \geq 1$ a natural number. Write Λ for von Mangoldt's function, φ for Euler's function and χ_d for the quadratic character modulo d, the Legendre symbol when d is odd. The *weight* of a natural number ν is $\lambda_{d,M}(\nu) = \Lambda(\nu)(1 - \chi_d(\nu))$ if $\nu \equiv 1 \pmod M$, and 0 otherwise. For $d \equiv 3 \pmod 4$ it is carried by the powers of d and by the odd powers of the primes that are inert in $\mathbb{Q}(\sqrt{-d})$, in the residue class 1 modulo M. The *remainder* is, for real $x \geq 1$,

$$R_{d,M}(x) = \sum_{1 \leq \nu \leq x} \lambda_{d,M}(\nu)\Big(\frac{1}{\nu} - \frac{1}{x}\Big) - \frac{\log x}{\varphi(M)} - \kappa_{d,M},$$

where the constant $\kappa_{d,M}$ is formed from the logarithmic derivatives at $s = 1$ of the L-functions of the Dirichlet characters ξ modulo M and of their twists $\xi\chi_d$ (Definitions 2.6 and 2.7). For a Dirichlet character χ we write $\tilde{L}(s, \chi)$ for the entire function $L(s, \chi)$, or $(s-1)L(s, \chi)$ if χ is principal, and $\operatorname{ord}_s f$ for the order of vanishing at s of an entire function $f \neq 0$. A function $\mathcal{E}\colon \mathbb{R} \to \mathbb{R}$ is *polar with residue function* $\omega\colon \mathbb{C} \to \mathbb{C}$ (Definition 2.8) if $\mathcal{E}(v) = O(\mathrm{e}^v)$ and the transform $\int_0^\infty \mathcal{E}(v)\,\mathrm{e}^{(1-s)v}\,\mathrm{d}v$ continues to a meromorphic function Φ on $\mathbb{C}$ that has no pole in $\operatorname{Re} s \geq 1$ and satisfies $(s-\rho)\Phi(s) \to \omega(\rho)$ as $s \to \rho$, for every ρ with $\operatorname{Re}\rho > 0$.

Theorem 1 (zeros as poles)**.** Let d be a prime number with $d \equiv 7 \pmod 8$ and let $M \geq 1$ be a natural number with $\gcd(M, d) = 1$. For a complex number s put

$$\operatorname{res}_{d,M}(s) = \frac{1}{\varphi(M)\, s(1-s)} \sum_{\xi} \Big(\operatorname{ord}_s \tilde{L}(\,\cdot\,, \xi) - \operatorname{ord}_s \tilde{L}(\,\cdot\,, \xi\chi_d) \Big) \quad \text{for } s \neq 0, 1,$$

the sum over the Dirichlet characters ξ modulo M, and put $\operatorname{res}_{d,M}(0) = \operatorname{res}_{d,M}(1) = 0$. Then, as a function of the real variable v, $v \mapsto R_{d,M}(\mathrm{e}^v)$ is polar with residue function $s \mapsto \operatorname{res}_{d,M}(s)$.

Theorem 2 (the one-sided criterion)**.** Let $M \geq 1$ be a natural number, c an element of $\mathbb{Z}/M$ and β a real number. Assume that $\beta > \frac{1}{2}$, that c is a unit of $\mathbb{Z}/M$, and that every prime number d with $d \equiv c \pmod M$ has the following three properties: $d \equiv 7 \pmod 8$; $\gcd(M, d) = 1$; and

$$R_{d,M}(x) \leq x^{\beta - 1} \qquad \text{for all sufficiently large real } x.$$

Then for every complex number ρ with $\operatorname{Re}\rho > \beta$ and every Dirichlet character χ modulo M,

$$\tilde{L}(\rho, \chi) \neq 0.$$

Theorem 3 (a good point in every window)**.** Let $\mathcal{E}_1, \mathcal{E}_2 \colon \mathbb{R} \to \mathbb{R}$ and $\omega_1, \omega_2 \colon \mathbb{C} \to \mathbb{C}$ be functions such that $\mathcal{E}_1$ is polar with residue function ω_1 and $\mathcal{E}_2$ is polar with residue function ω_2. Then there is a real number v_* such that for every real $v_0 \geq v_*$ and every real X with $0 \leq X \leq \mathrm{e}^{v_0}$ there is a real number v_1 with $v_0 \leq v_1 \leq v_0^2$ and

$$\mathcal{E}_1(v_1) - X\,\mathcal{E}_2(v_1) \leq \mathrm{e}^{-v_0}.$$

In Theorem 2 the conclusion gives $L(\rho, \chi) \neq 0$, the point $\rho = 1$ excepted when χ is principal. The three theorems are used as follows in the last unit of the proof (Chapter I of the write-up). The geometric part of the proof bounds $R_{d,N_0}(x)$ from above by $x^{8\varepsilon - 1/2}$ for every $\varepsilon \in (0, \frac{1}{100})$, for a multiple N_0 of 18480 and every prime $d \equiv N_0/2 - 1 \pmod{N_0}$; Theorems 1 and 3 enter that deduction at one point, the choice of the second scale. Theorem 2 with $M = N_0$ and $c = N_0/2 - 1$ then turns the bound into $\tilde{L}(\rho, \chi) \neq 0$ for $\operatorname{Re}\rho > \frac{1}{2}$. The bound is one-sided, and it is needed for every prime of a class: §6 explains both points. Part II (§§8 to 11) needs the vocabulary of the data and of the forms, and its statements (Theorems 4, A, B and C) stand there.

2 The setting of Part I

Conventions. $\mathbb{N} = \{0, 1, 2, \dots\}$. For a natural number $M \geq 1$, a *Dirichlet character modulo M* is a multiplicative map $\mathbb{Z}/M \to \mathbb{C}$ that vanishes off the units; it is read as a function on $\mathbb{Z}$, and it is *principal* if it is 1 on the units. Sums over ξ run over all Dirichlet characters modulo M, and $\varphi(M)$ is their number. $\mathbf{1}$ is the Dirichlet character modulo 1. Λ is von Mangoldt's function, with $\Lambda(0) = 0$; log is the natural logarithm, e its base, and $(z)_+ = \max(z, 0)$ for real z. For an entire function $f \neq 0$ and $s \in \mathbb{C}$, $\operatorname{ord}_s f \in \mathbb{N}$ is the order of vanishing of f at s. A function is *analytic at a point* if it is holomorphic in a neighbourhood of it. *For all sufficiently large x* means: for all $x \geq x_*$, for some real x_*. Integrals are Lebesgue integrals; a family of complex numbers is *summable* if it is absolutely summable.

Definition 2.1 (the quadratic character and the twists)**.** Let d be a prime number. The Dirichlet character χ_d modulo d is the quadratic character of the field $\mathbb{Z}/d$, with values in $\{-1, 0, 1\}$: $\chi_d(n) = 0$ if $d \mid n$, $\chi_d(n) = 1$ if n is a non-zero square modulo d, and $\chi_d(n) = -1$ otherwise. For odd d it is the Legendre symbol, and for $d \equiv 3 \pmod 4$ it is the quadratic character χ_K of the field $K = \mathbb{Q}(\sqrt{-d})$. Let moreover $M \geq 1$ be a natural number and ξ a Dirichlet character modulo M. The *twist* $\xi\chi_d$ is the Dirichlet character modulo Md with $(\xi\chi_d)(n) = \xi(n)\,\chi_d(n)$ for every integer n.

LEAN `chiK` · `quadTwist` · `quadTwist_apply`

Definition 2.2 (the entire L-function)**.** Let $M \geq 1$ be a natural number and χ a Dirichlet character modulo M. The function $\tilde{L}(\,\cdot\,, \chi) \colon \mathbb{C} \to \mathbb{C}$, with values written $\tilde{L}(s, \chi)$, is the Dirichlet L-function $s \mapsto L(s, \chi)$ if χ is not principal, and the entire function that equals $(s-1)L(s, \chi)$ for $s \neq 1$ if χ is principal (its value at $s = 1$ is then $\prod_{p \mid M}(1 - 1/p)$, the residue of $L(s, \chi)$). In both cases it is entire and not identically zero. Its derivative is $\tilde{L}'$, and $\frac{\tilde{L}'}{\tilde{L}}(s, \chi)$ is the quotient of the two values at s.

LEAN entireL

Definition 2.3 (the Chowla–Selberg constant)**.** Let d be a prime number. Then

$$\mathrm{cs}(d) = \mathrm{C}_{\mathrm{Eu}} - \operatorname{Re} \frac{\tilde{L}'}{\tilde{L}}(1, \mathbf{1}\chi_d),$$

where C_{Eu} is Euler's constant and $\mathbf{1}\chi_d$ is the twist of the character modulo 1, that is, the character $n \mapsto \chi_d(n)$ modulo d.

LEAN chowlaSelbergConst

Definition 2.4 (the weight)**.** Let d be a prime number and let M and ν be natural numbers. Then

$$\lambda_{d,M}(\nu) = \Lambda(\nu)(1 - \chi_d(\nu)) \quad \text{if } \nu \equiv 1 \pmod{M}, \qquad \lambda_{d,M}(\nu) = 0 \quad \text{otherwise.}$$

LEAN lambdaClass

So $\lambda_{d,M}(\nu) \neq 0$ only if $\nu = p^e$ is a power of a prime, $\nu \equiv 1 \pmod{M}$, and either $p = d$ (the value is $\log d$) or $\chi_d(p) = -1$ and e is odd (the value is $2 \log p$).

Definition 2.5 (the weighted sums)**.** Let d be a prime number, let M and i be natural numbers and x a real number. Then

$$A_{d,M}(i, x) = x^{-i} \sum_{1 \le \nu \le x} \lambda_{d,M}(\nu)\, \nu^{\,i-1},$$

the sum over the natural numbers ν with $1 \le \nu \le x$; it is empty, and the value is 0, for $x < 1$.

LEAN lambdaSum

Definition 2.6 (the mean of the logarithmic derivatives)**.** Let d be a prime number, $M \ge 1$ a natural number and s a complex number. Then

$$G_{d,M}(s) = \frac{1}{\varphi(M)} \Big(\sum_{\xi} \Big(\frac{\tilde{L}'}{\tilde{L}}(s, \xi\chi_d) - \frac{\tilde{L}'}{\tilde{L}}(s, \xi) \Big) - 1 \Big), \qquad \kappa_{d,M} = \operatorname{Re} G_{d,M}(1),$$

the sum over the Dirichlet characters ξ modulo M. As a function of s it is meromorphic on $\mathbb{C}$, and it is analytic at every point where none of the functions $\tilde{L}(\,\cdot\,, \xi)$ and $\tilde{L}(\,\cdot\,, \xi\chi_d)$ vanishes.

LEAN logDerivMean

Definition 2.7 (the remainder)**.** Let d be a prime number, $M \ge 1$ a natural number and x a real number. Then

$$R_{d,M}(x) = A_{d,M}(0, x) - A_{d,M}(1, x) - \frac{\log x}{\varphi(M)} - \kappa_{d,M} = \sum_{1 \le \nu \le x} \lambda_{d,M}(\nu) \Big(\frac{1}{\nu} - \frac{1}{x} \Big) - \frac{\log x}{\varphi(M)} - \kappa_{d,M},$$

with $\kappa_{d,M} = \operatorname{Re} G_{d,M}(1)$ as in Definition 2.6.

LEAN primeError

Definition 2.8 (polar functions)**.** Let $\mathcal{E}\colon \mathbb{R} \to \mathbb{R}$ and $\omega\colon \mathbb{C} \to \mathbb{C}$ be functions. We say that $\mathcal{E}$ is polar with residue function ω, and write $\mathrm{Polar}(\mathcal{E}, \omega)$, if $\mathcal{E}$ is Borel measurable and there are a real number C and a function $\Phi\colon \mathbb{C} \to \mathbb{C}$, meromorphic on $\mathbb{C}$ and defined at every point (at a pole its value is arbitrary), with the following four properties.

(P1) $|\mathcal{E}(v)| \le C\,\mathrm{e}^{v}$ for every real $v \ge 0$.

(P2) $\Phi(s) = \int_0^\infty \mathcal{E}(v)\,\mathrm{e}^{(1-s)v}\,\mathrm{d}v$ for every $s \in \mathbb{C}$ with $\mathrm{Re}\, s > 2$.

(P3) The function $s \mapsto (s-1)\Phi(s)$, whose value at $s = 1$ is 0 whatever $\Phi(1)$ is, is analytic at every point of the closed half-plane $\mathrm{Re}\, s \ge 1$.

(P4) For every $\rho \in \mathbb{C}$ with $\mathrm{Re}\, \rho > 0$: $(s-\rho)\Phi(s) \to \omega(\rho)$ as $s \to \rho$, $s \ne \rho$.

LEAN `IsPolar`

Remark 2.9 (how to read the definition)**.** By (P1) and the measurability, the integral in (P2) converges absolutely for $\mathrm{Re}\, s > 2$, so Φ is the meromorphic continuation of the Laplace transform of $v \mapsto \mathcal{E}(v)\mathrm{e}^{v}$, and it is unique. (P4) says that the poles of Φ in the half-plane $\mathrm{Re}\, s > 0$ are at most simple, and that $\omega(\rho)$ is the residue at ρ; so $\omega(\rho) = 0$ exactly when Φ is analytic at ρ (after correcting its value there). The clause of (P3) on the value at $s = 1$ is essential: (P3) says that Φ is analytic at every point $s \ne 1$ of $\mathrm{Re}\, s \ge 1$, and that near $s = 1$ it is the quotient by $s - 1$ of an analytic function that vanishes at 1: the singularity at $s = 1$ is removable. Hence a polar function has $\omega(\rho) = 0$ for $\mathrm{Re}\, \rho \ge 1$. Read without the clause, for a meromorphic function with its removable singularities filled in, (P3) would allow a simple pole of Φ at $s = 1$; the constant function 1, with $\Phi(s) = 1/(s-1)$, would then be polar, and Theorem 3 would be false for the constant functions 1 and 0. The values of ω on $\mathrm{Re}\, \rho \le 0$ play no role.

Remark 2.10 (what the remainder measures; not part of the formal text)**.** By the orthogonality of characters, for $\mathrm{Re}\, s > 1$ and $\gcd(M, d) = 1$, $d \ne 2$,

$$\sum_{\nu \ge 1} \lambda_{d,M}(\nu)\,\nu^{-s} = G_{d,M}(s) + \frac{s}{\varphi(M)(s-1)}$$

(this is step 3 of the proof of Theorem 1). The only singularity on $\mathrm{Re}\, s \ge 1$ is the simple pole at $s = 1$ with residue $1/\varphi(M)$, which comes from the principal character. Accordingly one expects $\sum_{\nu \le x} \lambda_{d,M}(\nu)/\nu = \log x/\varphi(M) + \text{constant} + o(1)$ and $x^{-1}\sum_{\nu \le x} \lambda_{d,M}(\nu) = 1/\varphi(M) + o(1)$, and the constant $\kappa_{d,M}$ is the one for which $R_{d,M}(x)$ has no constant term: in the language of Definition 2.8, the one for which the transform has no pole at $s = 1$. A zero ρ of some $\tilde{L}(\,\cdot\,, \xi)$ with $0 < \mathrm{Re}\, \rho < 1$ gives the transform a pole with residue $\mathrm{ord}_\rho\, \tilde{L}(\,\cdot\,, \xi)/(\varphi(M)\rho(1-\rho))$, hence, formally, a term of size $x^{\mathrm{Re}\,\rho - 1}$ in $R_{d,M}(x)$; a zero of a twist $\tilde{L}(\,\cdot\,, \xi\chi_d)$ does the same with the opposite sign. So the bound $R_{d,M}(x) = O(x^{\beta-1})$ is what one expects if there is no zero with $\mathrm{Re}\, \rho > \beta$, and the generalised Riemann hypothesis corresponds to $\beta = \frac{1}{2}$. Theorem 2 goes in the other direction, and it asks for an upper bound only.

3 Quoted results

Part I rests on seven results that the artifact proves in its background library, from Mathlib, and we quote all seven. Six of them are classical or elementary. The seventh, Input 5, is not: the theorem that its source names treats real characters, and the formal statement also covers the quadratic twists of non-real characters, by an estimate for each fixed character that the library proves itself; its box says exactly what is proved and what the cited theorem gives. Each box gives the statement as the formal text has it, the unit that owns it, and what is known about its source: the comparison with the literature that the second reader of this write-up made for three of them, and otherwise the entry of the catalogue of quoted results. *Reference to be confirmed* means that there is no reference with a confirmed place.

Input 1 (non-vanishing on $\operatorname{Re} s \geq 1$; unit 107)**.** Let $M \geq 1$ be a natural number, χ a Dirichlet character modulo M and s a complex number with $\operatorname{Re} s \geq 1$. Then $\tilde{L}(s, \chi) \neq 0$.

Classical: Hadamard and de la Vallée Poussin on the line $\operatorname{Re} s = 1$, Dirichlet at $s = 1$. In the formal text it is a direct consequence of two theorems of Mathlib, at the version that the artifact pins, after the principal case is split off: for non-principal χ, $L(s, \chi) \neq 0$ on $\operatorname{Re} s \geq 1$; for principal χ and $s \neq 1$ both factors of $(s-1)L(s, \chi)$ are non-zero; and at $s = 1$ the entire function has the value $\prod_{p \mid M}(1 - 1/p) \neq 0$. Relation: the theorem itself. The comparison with Mathlib at the pin was made by the second reader of this write-up.

LEAN `entireL_ne_zero`

Input 2 (the logarithmic derivative; unit 107)**.** Let $M \geq 1$ be a natural number, χ a Dirichlet character modulo M and s a complex number.
(a) If $\operatorname{Re} s > 1$, the family $\left(\chi(\nu)\Lambda(\nu)\nu^{-s}\right)_{\nu \geq 1}$ is summable, with sum

$$\sum_{\nu \geq 1} \chi(\nu)\Lambda(\nu)\, \nu^{-s} = \frac{[\chi \text{ principal}]}{s-1} - \frac{\tilde{L}'}{\tilde{L}}(s, \chi),$$

where the bracket $[\chi \text{ principal}]$ is the number 1 if χ is principal and 0 otherwise.
(b) $\operatorname{ord}_s \tilde{L}(\,\cdot\,, \chi) = 0$ if and only if $\tilde{L}(s, \chi) \neq 0$; and $(s'-s)\,\frac{\tilde{L}'}{\tilde{L}}(s', \chi) \to \operatorname{ord}_s \tilde{L}(\,\cdot\,, \chi)$ as $s' \to s$, $s' \neq s$.

Elementary: (a) is the logarithmic derivative of the Euler product, (b) the residue of the logarithmic derivative of an analytic function. The catalogue names Davenport, *Multiplicative Number Theory*, for (a), without a place: reference to be confirmed.

LEAN `LSeriesHasSum_mul_vonMangoldt` · `tendsto_sub_mul_logDeriv_entireL`

Input 3 (twists are not principal; unit 107)**.** Let M be a natural number, ξ a Dirichlet character modulo M and d a prime number with $d \neq 2$ and $\gcd(M, d) = 1$. Then the twist $\xi\chi_d$ is not the principal character modulo Md.

Elementary (the Chinese remainder theorem gives n with $n \equiv 1 \pmod{M}$ and $\chi_d(n) = -1$).

LEAN `quadTwist_ne_one`

Input 4 (Landau's lemma; unit 107). Let $\mathcal{E}\colon \mathbb{R} \to \mathbb{R}$ and $\omega\colon \mathbb{C} \to \mathbb{C}$ be functions such that $\mathcal{E}$ is polar with residue function ω, and let β be a real number with $\beta > 0$. Assume that $\operatorname{Re}\omega(s) \geq 0$ for every real number $s > \beta$, and that $\mathcal{E}(v) \leq \mathrm{e}^{(\beta-1)v}$ for all sufficiently large real v. Then $\omega(\rho) = 0$ for every complex number ρ with $\operatorname{Re}\rho > \beta$.

Relation to the literature, as compared by the second reader of this write-up from the pinned Lean text and the primary texts (the writer has not consulted them): a corollary of D. V. Widder, *The Laplace Transform*, Chapter II, §5, Theorem 5b, p. 58 [Wi], with a residue argument. Widder's theorem concerns the Laplace–Stieltjes transform of a monotone function with a finite abscissa of convergence, and gives a singularity at the real point of the abscissa; it applies to the primitive of the non-negative measurable function $v \mapsto C_1\mathrm{e}^{\beta v} - \mathcal{E}(v)\mathrm{e}^{v}$, for a suitable constant C_1. What the formal statement adds is the step at that real point, which compares the sign of the residue with positivity (Remark 3.1). The header of the formal file names H. L. Montgomery and R. C. Vaughan, *Multiplicative Number Theory I*, §15.1, Lemma 15.1, p. 463 [MV], as the source; that lemma is the same theorem for a density that is Riemann integrable on bounded intervals and of eventually constant sign, whereas $\mathcal{E}$ is only assumed measurable here, so it does not apply as it stands.

LEAN `IsPolar.landau`

Input 5 (a zero-free box for quadratic twists; unit 127). Let $M \geq 1$ be a natural number, β and z real numbers and c an element of $\mathbb{Z}/M$. Assume that $\beta > \frac{1}{2}$, that c is a unit of $\mathbb{Z}/M$, and that every prime number d with $d \equiv c \pmod{M}$ satisfies $d \equiv 7 \pmod{8}$ and $\gcd(M, d) = 1$. Then there is a prime number d with $d \equiv c \pmod{M}$ such that

$$\tilde{L}(s, \xi\chi_d) \neq 0$$

for every Dirichlet character ξ modulo M and every complex number s with $\operatorname{Re} s \geq \beta$ and $|\operatorname{Im} s| \leq z$.

The number z is any real number; for $z < 0$ the condition on s is empty, and the statement still gives a prime. *What the formal library proves*, in two steps that the writer read in the Lean text. First, an estimate for one character: for every Dirichlet character ξ modulo M, real or not, every real number $\Delta > 0$ and every real z, the number of the primes $d \leq x$ with $d \equiv 7 \pmod{8}$ and $\gcd(M, d) = 1$ for which $\tilde{L}(\,\cdot\,, \xi\chi_d)$ has a zero s with $\operatorname{Re} s \geq \frac{1}{2} + 9\Delta$ and $|\operatorname{Im} s| \leq z$ is $O(x^{1-\Delta/2})$ as $x \to \infty$. The proof passes to the primitive character that induces ξ, and uses a three-lines argument and a smoothed mean square of sums of Jacobi symbols. Second, the bounds for the $\varphi(M)$ characters ξ are added and set against the divergence of $\sum 1/p$ over the primes $p \equiv c \pmod{M}$: if every prime of the class failed for some ξ, that sum would converge. *What the literature gives*, as compared by the second reader of this write-up from the pinned Lean text and the primary text (the writer has not consulted it): the header of the formal file names M. Jutila, On mean values of Dirichlet polynomials with real characters, Acta Arith. 27 (1975), 191–198; its Theorem 2, equation (6), p. 193 [Ju], bounds the number of zeros in a box, summed over real characters. For a non-real character ξ the twists $\xi\chi_d$ are not real, so that theorem alone does not give the first step, and it does not contain the second. Input 5 is therefore not a classical theorem in the form used here: it is the combination of a variant of a classical zero-density estimate, for which no published place has been confirmed, with the divergence of a sum over primes. The catalogue of quoted results records it in this way.

LEAN `exists_entireL_quadTwist_ne_zero`

Input 6 (Laplace integrals; unit 107)**.** *(a)* Let s be a complex number with $\operatorname{Re} s > 0$ and i a natural number. Then $\int_0^\infty v^i\, \mathrm{e}^{-sv}\, \mathrm{d}v = i!/s^{i+1}$.
(b) Let $\mathcal{E}\colon \mathbb{R} \to \mathbb{R}$ be a Borel measurable function, C a real number with $|\mathcal{E}(v)| \le C\mathrm{e}^v$ for every real $v \ge 0$, and s a complex number with $\operatorname{Re} s > 2$. Then $v \mapsto \mathcal{E}(v)\, \mathrm{e}^{(1-s)v}$ is integrable on $(0, \infty)$.

Elementary: (a) is the integral of the Gamma function.

LEAN `laplace_pow` · `integrableOn_laplace_of_abs_le`

Input 7 (Taylor series across a removable singularity; unit 107)**.** Let $\Phi\colon \mathbb{C} \to \mathbb{C}$ be a function, $\mathfrak{r}_0$ a real number and s_0, s_1, s_2 complex numbers. Assume that the function $s \mapsto (s - s_1)\Phi(s)$ is analytic at every point of the open disc $|s - s_0| < \mathfrak{r}_0$, and that $s_0 \ne s_1$, $|s_1 - s_0| < \mathfrak{r}_0$ and $|s_2 - s_0| < \mathfrak{r}_0$. Then the family $\left((s_2 - s_0)^i\, \Phi^{(i)}(s_0)/i!\right)_{i \ge 0}$ is summable, where $\Phi^{(i)}$ is the i-th complex derivative.

Elementary. The function $s \mapsto (s - s_1)\Phi(s)$ vanishes at s_1, because it is a product with the factor $s - s_1$ whatever the value $\Phi(s_1)$ is; being analytic, it is divisible by $s - s_1$. So off s_1 the function Φ agrees with a function analytic in the disc, with the same derivatives at s_0, and the Taylor series of that function at s_0 converges absolutely in the disc. Analyticity of the product without the vanishing would allow a simple pole of Φ at s_1.

LEAN `summable_taylor_of_removable`

Remark 3.1 (from the classical lemma to Input 4; our derivation)**.** In the formal library Input 4 is proved directly, by the Taylor expansion at a real point that proves the classical lemma. Here is how it follows from the classical statement in this form (its relation to Widder's theorem is described in the box of Input 4): *if $\mathcal{E}_0 \ge 0$ on $(0, \infty)$ and the Laplace integral $\int_0^\infty \mathcal{E}_0(v)\mathrm{e}^{-sv}\mathrm{d}v$ converges for some real s but not for all, then the function that it defines to the right of its abscissa of convergence x_0 has no analytic continuation to a neighbourhood of the point x_0.* Let C and Φ be as in Definition 2.8, let $\mathcal{E}(v) \le \mathrm{e}^{(\beta-1)v}$ for $v \ge v_* \ge 0$, and put $C_1 = \max(1, |C|\mathrm{e}^{2v_*})$. Then $\mathcal{E}_0(v) = C_1\, \mathrm{e}^{\beta v} - \mathcal{E}(v)\mathrm{e}^v$ is ≥ 0 for all $v > 0$: for $v \ge v_*$ because $\mathcal{E}(v)\mathrm{e}^v \le \mathrm{e}^{\beta v}$, and for $v < v_*$ because $\mathcal{E}(v)\mathrm{e}^v \le |C|\mathrm{e}^{2v_*} \le C_1\mathrm{e}^{\beta v}$. Its Laplace integral converges for $\operatorname{Re} s > \max(2, \beta)$, where by (P2) it equals $C_1/(s-\beta) - \Phi(s)$, a function meromorphic on $\mathbb{C}$. Suppose that the abscissa of convergence x_0 is $> \beta$. To the right of x_0 the integral is analytic, so by the identity theorem it equals $C_1/(s-\beta) - \Phi(s)$ on all of $\operatorname{Re} s > x_0$; for real $s > x_0$ it is ≥ 0. Multiplying by $s - x_0 > 0$ and letting s decrease to x_0, (P4) gives $-\omega(x_0) \ge 0$. With the hypothesis $\operatorname{Re}\omega(x_0) \ge 0$ this forces $\omega(x_0) = 0$, so $C_1/(s-\beta) - \Phi(s)$ is analytic at x_0, against the classical lemma. Hence $x_0 \le \beta$: the integral is analytic in $\operatorname{Re} s > \beta$ and equals $C_1/(s-\beta) - \Phi(s)$ there, so Φ has no pole in $\operatorname{Re} s > \beta$, and $\omega(\rho) = 0$ for $\operatorname{Re}\rho > \beta$ by (P4). Note that the hypothesis does not ask that Φ be analytic at the real points to the right of β: poles there whose residue has non-negative real part are allowed, and the conclusion says that there are none. This is the form in which the lemma is used below.

4 Elementary properties of the weight and of the remainder

Lemma 4.1 (bounds for the weight)**.** *Let d be a prime number and let M and ν be natural numbers. Then $0 \le \lambda_{d,M}(\nu)$ and $|\lambda_{d,M}(\nu)| \le 2\nu$.*

Proof. $0 \le \Lambda(\nu) \le \log \nu \le \nu$ for $\nu \ge 1$, $\Lambda(0) = 0$, and $1 - \chi_d(\nu) \in \{0, 1, 2\}$. □

LEAN `lambdaClass_nonneg_and_abs_le`

Lemma 4.2 (bound for the weighted sums)**.** *Let d be a prime number, let M and i be natural numbers and v a real number. Then $|A_{d,M}(i, \mathrm{e}^v)| \le 2\,\mathrm{e}^v$.*

Proof. Put $x = \mathrm{e}^v$. By Lemma 4.1, $|\lambda_{d,M}(\nu)|\,\nu^{\,i-1} \le 2\nu^{\,i} \le 2x^i$ for $1 \le \nu \le x$, and the sum in Definition 2.5 has at most x terms. So $|A_{d,M}(i,x)| \le x^{-i} \cdot x \cdot 2x^i = 2x$. □

LEAN `abs_lambdaSum_exp_le`

Lemma 4.3 (the remainder as a sum of positive parts)**.** *Let d be a prime number, let $M \ge 1$ and a be natural numbers, and let x be a real number with $0 < x$ and $x \le a$. Then*

$$R_{d,M}(x) = \frac{1}{a}\sum_{\nu=1}^{a} \lambda_{d,M}(\nu)\Big(\frac{a}{\nu} - \frac{a}{x}\Big)_+ - \frac{\log x}{\varphi(M)} - \kappa_{d,M}.$$

Proof. $a \ge x > 0$, so $a \ge 1$. For $1 \le \nu \le a$ the number $\frac{1}{a}(\frac{a}{\nu} - \frac{a}{x})_+ = (\frac{1}{\nu} - \frac{1}{x})_+$ is $\frac{1}{\nu} - \frac{1}{x}$ if $\nu \le x$ and 0 if $\nu > x$. So the sum is $\sum_{1 \le \nu \le x} \lambda_{d,M}(\nu)(\frac{1}{\nu} - \frac{1}{x}) = A_{d,M}(0,x) - A_{d,M}(1,x)$, and the claim is Definition 2.7. □

LEAN `primeError_eq_sum`

This identity is the reason for the shape of the remainder. In Part II the prime sums of the data have the form $\sum_{\nu \le a} \lambda_{d,M}(\nu)(z/\nu - w)_+$ with a real *order* z and a real *weight* w; with $z = a$ and $w = a/x$ this is a times the sum of the lemma.

Lemma 4.4 (the constant for the modulus 1)**.** *Let d be a prime number. Then $\operatorname{Re} G_{d,1}(1) = -1 - \operatorname{cs}(d)$; in other words $\kappa_{d,1} = -1 - \operatorname{cs}(d)$.*

Proof. Modulo 1 there is one Dirichlet character, $\mathbf{1}$, and $\varphi(1) = 1$; so $G_{d,1}(s) = \frac{\tilde L'}{\tilde L}(s, \mathbf{1}\chi_d) - \frac{\tilde L'}{\tilde L}(s, \mathbf{1}) - 1$. The function $\tilde L(\,\cdot\,, \mathbf{1})$ is $s \mapsto (s-1)\zeta(s)$, where ζ is the Riemann zeta function; from the expansion $\zeta(s) = 1/(s-1) + \mathrm{C}_{\mathrm{Eu}} + O(s-1)$ at $s = 1$ its value at 1 is 1 and its derivative at 1 is C_{Eu}, so $\frac{\tilde L'}{\tilde L}(1, \mathbf{1}) = \mathrm{C}_{\mathrm{Eu}}$. Hence $\operatorname{Re} G_{d,1}(1) = \operatorname{Re} \frac{\tilde L'}{\tilde L}(1, \mathbf{1}\chi_d) - \mathrm{C}_{\mathrm{Eu}} - 1 = -\operatorname{cs}(d) - 1$ by Definition 2.3. □

LEAN `re_logDerivMean_one`

5 The transform of the remainder: proof of Theorem 1

Let d and M be as in Theorem 1: d is a prime with $d \equiv 7 \pmod 8$, $M \ge 1$ and $\gcd(M, d) = 1$. Put

$$\Phi_{d,M}(s) = \frac{1}{s-1}\Big(\frac{G_{d,M}(s)}{s} - \kappa_{d,M}\Big) \qquad (s \in \mathbb{C},\ s \ne 1), \tag{5.1}$$

and $\Phi_{d,M}(1) = 0$; the value at $s = 1$ plays no role. We verify Definition 2.8 for $\mathcal{E}(v) = R_{d,M}(\mathrm{e}^v)$ and $\omega(s) = \operatorname{res}_{d,M}(s)$, with the constant $C = |\kappa_{d,M}| + 5$ and the function $\Phi = \Phi_{d,M}$. The proof has seven steps.

Step 1: analyticity. By Input 1 none of the functions $\tilde{L}(\,\cdot\,,\xi)$ and $\tilde{L}(\,\cdot\,,\xi\chi_d)$, ξ modulo M, has a zero in $\operatorname{Re} s \geq 1$. So $s \mapsto G_{d,M}(s)$ is analytic at every point of $\operatorname{Re} s \geq 1$ (Definition 2.6), and so is the function $s \mapsto G_{d,M}(s)/s - \kappa_{d,M}$. As a quotient of meromorphic functions, $\Phi_{d,M}$ is meromorphic on $\mathbb{C}$.

Step 2: measurability and (P1). For $i = 0, 1$ the function $v \mapsto A_{d,M}(i, \mathrm{e}^v)$ is the product of e^{-iv} and a step function, and $v \mapsto v/\varphi(M) + \kappa_{d,M}$ is continuous; so $v \mapsto R_{d,M}(\mathrm{e}^v)$ is Borel measurable. For $v \geq 0$, Lemma 4.2 gives

$$|R_{d,M}(\mathrm{e}^v)| \leq 2\mathrm{e}^v + 2\mathrm{e}^v + \frac{v}{\varphi(M)} + |\kappa_{d,M}| \leq \bigl(|\kappa_{d,M}| + 5\bigr)\,\mathrm{e}^v,$$

because $v \leq \mathrm{e}^v$, $\varphi(M) \geq 1$ and $1 \leq \mathrm{e}^v$.

Step 3: the Dirichlet series of the weight. For $\operatorname{Re} s > 1$ the family $(\lambda_{d,M}(\nu)\nu^{-s})_{\nu \geq 1}$ is summable, and

$$\sum_{\nu \geq 1} \lambda_{d,M}(\nu)\,\nu^{-s} = G_{d,M}(s) + \frac{s}{\varphi(M)\,(s-1)}. \tag{5.2}$$

Indeed, by the orthogonality of characters the indicator of the class $\nu \equiv 1 \pmod M$ is $\varphi(M)^{-1}\sum_\xi \xi(\nu)$, so $\lambda_{d,M}(\nu) = \varphi(M)^{-1}\sum_\xi (\xi(\nu) - (\xi\chi_d)(\nu))\Lambda(\nu)$ by Definitions 2.4 and 2.1. Input 2(a), for the characters ξ modulo M and $\xi\chi_d$ modulo Md, gives

$$\sum_{\nu \geq 1} \lambda_{d,M}(\nu)\,\nu^{-s} = \frac{1}{\varphi(M)} \sum_{\xi} \Bigl(\frac{[\xi \text{ principal}] - [\xi\chi_d \text{ principal}]}{s-1} - \frac{\tilde{L}'}{\tilde{L}}(s,\xi) + \frac{\tilde{L}'}{\tilde{L}}(s,\xi\chi_d) \Bigr).$$

Here $[\xi\chi_d \text{ principal}] = 0$ for every ξ, by Input 3: $d \neq 2$ because $d \equiv 7 \pmod 8$, and $\gcd(M, d) = 1$. And $\sum_\xi [\xi \text{ principal}] = 1$. So the right side is $G_{d,M}(s) + \varphi(M)^{-1}(1 + \frac{1}{s-1})$, which is (5.2). This is the only place where the hypothesis $d \equiv 7 \pmod 8$ enters the proof.

Step 4: the transforms of the weighted sums. Let $\operatorname{Re} s > 2$ and $i \in \{0, 1\}$. By Lemma 4.2 and Input 6(b) the function $v \mapsto A_{d,M}(i, \mathrm{e}^v)\mathrm{e}^{(1-s)v}$ is integrable on $(0, \infty)$, and

$$(s + i - 1) \int_0^\infty A_{d,M}(i, \mathrm{e}^v)\,\mathrm{e}^{(1-s)v}\,\mathrm{d}v = \sum_{\nu \geq 1} \lambda_{d,M}(\nu)\,\nu^{-s}. \tag{5.3}$$

To see this, substitute $x = \mathrm{e}^v$: the integral is

$$\int_1^\infty A_{d,M}(i,x)\,x^{-s}\,\mathrm{d}x = \int_1^\infty \Bigl(\sum_{1 \leq \nu \leq x} \lambda_{d,M}(\nu)\,\nu^{\,i-1} \Bigr)\, x^{-(s+i-1)-1}\,\mathrm{d}x.$$

The coefficients $\lambda_{d,M}(\nu)\nu^{i-1}$ are ≥ 0, and their sum up to x is $x^i A_{d,M}(i,x) \leq 2x^{1+i}$ by Lemma 4.2. Partial summation, in the form that Mathlib provides, says that a Dirichlet series whose coefficients have absolute partial sums $O(x^{1+i})$ is, at every s' with $\operatorname{Re} s' > 1 + i$, equal to s' times the integral over $(1, \infty)$ of its partial sums against $x^{-s'-1}$. With $s' = s + i - 1$, whose real part exceeds $1 + i$ because $\operatorname{Re} s > 2$, this is (5.3).

Step 5: (P2). Let $\operatorname{Re} s > 2$. By Input 6(a) at the point $s-1$, $\int_0^\infty \mathrm{e}^{(1-s)v}\mathrm{d}v = \frac{1}{s-1}$ and $\int_0^\infty v\,\mathrm{e}^{(1-s)v}\mathrm{d}v = \frac{1}{(s-1)^2}$. By Definition 2.7, $R_{d,M}(\mathrm{e}^v) = A_{d,M}(0,\mathrm{e}^v) - A_{d,M}(1,\mathrm{e}^v) - v/\varphi(M) - \kappa_{d,M}$; each of the four terms, times $\mathrm{e}^{(1-s)v}$, is integrable on $(0,\infty)$. So by (5.3) for $i=0$ and $i=1$, and by (5.2),

$$\int_0^\infty R_{d,M}(\mathrm{e}^v)\,\mathrm{e}^{(1-s)v}\,\mathrm{d}v = \Big(\frac{1}{s-1} - \frac{1}{s}\Big)\Big(G_{d,M}(s) + \frac{s}{\varphi(M)(s-1)}\Big) - \frac{1}{\varphi(M)(s-1)^2} - \frac{\kappa_{d,M}}{s-1}$$
$$= \frac{G_{d,M}(s)}{s(s-1)} - \frac{\kappa_{d,M}}{s-1} = \Phi_{d,M}(s).$$

The term $\log x/\varphi(M)$ of the remainder has cancelled the double pole at $s=1$ that the pole of the Dirichlet series produces.

Step 6: the constant is real, and (P3). We claim that $G_{d,M}(1) = \kappa_{d,M}$, that is, that $G_{d,M}(1)$ is real. For real $s > 2$ the number $\Phi_{d,M}(s)$ is the integral of a real function, by Step 5; so $G_{d,M}(s)/s - \kappa_{d,M} = (s-1)\Phi_{d,M}(s)$ is real. By Step 1 the function $s \mapsto \operatorname{Im}(G_{d,M}(s)/s - \kappa_{d,M})$ of the real variable s is real analytic on a neighbourhood of the half-line $[1,\infty)$; it vanishes on $(2,\infty)$, hence on $[1,\infty)$, by the identity theorem. At $s=1$ this gives $\operatorname{Im} G_{d,M}(1) = 0$, and $\operatorname{Re} G_{d,M}(1) = \kappa_{d,M}$ by definition. Now (P3): for $s \neq 1$, $(s-1)\Phi_{d,M}(s) = G_{d,M}(s)/s - \kappa_{d,M}$, and at $s=1$ the left side is 0 and the right side is $G_{d,M}(1) - \kappa_{d,M} = 0$. So $s \mapsto (s-1)\Phi_{d,M}(s)$ is the function of Step 1, which is analytic at every point of $\operatorname{Re} s \geq 1$. This is the role of the constant $\kappa_{d,M}$ in the remainder: it removes the pole of the transform at $s=1$.

Step 7: (P4). Let $\operatorname{Re}\rho > 0$. If $\rho = 1$, then $(s-1)\Phi_{d,M}(s) \to 0 = \operatorname{res}_{d,M}(1)$ by Step 6. Let $\rho \neq 1$. By Input 2(b), applied to each ξ and to each $\xi\chi_d$,

$$(s-\rho)\,G_{d,M}(s) \;\longrightarrow\; \frac{1}{\varphi(M)}\sum_{\xi}\big(\operatorname{ord}_\rho \tilde{L}(\,\cdot\,,\xi\chi_d) - \operatorname{ord}_\rho \tilde{L}(\,\cdot\,,\xi)\big) \qquad (s\to\rho,\ s\neq\rho),$$

the constant -1 in $G_{d,M}(s)$ contributing nothing. Since $s \to \rho \neq 0$, $s-1 \to \rho-1 \neq 0$ and $(s-\rho)\kappa_{d,M} \to 0$, (5.1) gives

$$(s-\rho)\,\Phi_{d,M}(s) \;\longrightarrow\; \frac{1}{\varphi(M)\,\rho(\rho-1)}\sum_{\xi}\big(\operatorname{ord}_\rho \tilde{L}(\,\cdot\,,\xi\chi_d) - \operatorname{ord}_\rho \tilde{L}(\,\cdot\,,\xi)\big) = \operatorname{res}_{d,M}(\rho).$$

This proves Theorem 1. □

LEAN isPolar_primeError

6 The one-sided criterion: proof of Theorem 2

Let M, c, β be as in Theorem 2, let $\rho \in \mathbb{C}$ with $\operatorname{Re}\rho > \beta$, and let χ be a Dirichlet character modulo M. If $\operatorname{Re}\rho \geq 1$, then $\tilde{L}(\rho,\chi) \neq 0$ by Input 1. Assume $\operatorname{Re}\rho < 1$.

Step 1: the prime d. The hypotheses of Input 5 hold for M, β, c and $z = |\operatorname{Im}\rho|$: they are part of the hypotheses of Theorem 2. So there is a prime $d \equiv c \pmod M$ with

$$\tilde{L}(s,\xi\chi_d) \neq 0 \qquad \text{for all } \xi \text{ modulo } M \text{ and all } s \text{ with } \operatorname{Re} s \geq \beta,\ |\operatorname{Im} s| \leq |\operatorname{Im}\rho|. \tag{6.1}$$

By hypothesis this d satisfies $d \equiv 7 \pmod 8$, $\gcd(M,d) = 1$, and $R_{d,M}(x) \leq x^{\beta-1}$ for all sufficiently large x.

Step 2: the polar function. By Theorem 1, $v \mapsto R_{d,M}(\mathrm{e}^v)$ is polar with residue function $s \mapsto \mathrm{res}_{d,M}(s)$. We check the two hypotheses of Input 4 for it, with the exponent $\beta > \frac{1}{2} > 0$.

The one-sided bound. If v is large, so is e^v, and then $R_{d,M}(\mathrm{e}^v) \le (\mathrm{e}^v)^{\beta-1} = \mathrm{e}^{(\beta-1)v}$.

The sign of the residues at real points. Let s be a real number with $s > \beta$. If $s \ge 1$, no $\tilde{L}(\,\cdot\,,\xi)$ and no $\tilde{L}(\,\cdot\,,\xi\chi_d)$ vanishes at s (Input 1), all orders at s are 0 (Input 2(b)), and $\mathrm{res}_{d,M}(s) = 0$. If $\beta < s < 1$, the point s lies in the box of (6.1), so $\mathrm{ord}_s\, \tilde{L}(\,\cdot\,,\xi\chi_d) = 0$ for all ξ, and

$$\mathrm{res}_{d,M}(s) = \frac{1}{\varphi(M)\, s(1-s)} \sum_{\xi} \mathrm{ord}_s\, \tilde{L}(\,\cdot\,,\xi) \;\ge\; 0,$$

because $s(1-s) > 0$.

Step 3: conclusion. Input 4 gives $\mathrm{res}_{d,M}(\rho) = 0$. The point ρ lies in the box of (6.1), so again $\mathrm{ord}_\rho\, \tilde{L}(\,\cdot\,,\xi\chi_d) = 0$ for all ξ; and $\rho(1-\rho) \ne 0$ because $0 < \mathrm{Re}\,\rho < 1$. Hence $\sum_\xi \mathrm{ord}_\rho\, \tilde{L}(\,\cdot\,,\xi) = 0$. The summands are natural numbers, so each is 0; in particular $\mathrm{ord}_\rho\, \tilde{L}(\,\cdot\,,\chi) = 0$, that is, $\tilde{L}(\rho,\chi) \ne 0$ by Input 2(b). □

LEAN `entireL_ne_zero_of_primeError_le`

Remark 6.1 (the anatomy of the criterion)**.** *Where positivity comes from.* Landau's lemma needs a transform whose poles to the right of β, if real, have residues of one sign. In $\mathrm{res}_{d,M}(s)$ the zeros of the $\tilde{L}(\,\cdot\,,\xi)$ count positively and those of the twists $\tilde{L}(\,\cdot\,,\xi\chi_d)$ negatively. The twists are present because the weight $\lambda_{d,M}(\nu)$ carries the factor $1 - \chi_d(\nu)$; this factor is what the geometric part of the proof can bound, since it selects the primes that do not split in $K = \mathbb{Q}(\sqrt{-d})$. Input 5 removes the negative terms from a box of the height of ρ.

Why every prime of a class. The prime d is not chosen in advance: Input 5 produces it, and it depends on the height $|\,\mathrm{Im}\,\rho|$ of the point at which a zero is to be excluded. So the one-sided bound must be known for every prime of the class c.

Why an upper bound suffices. The lemma is applied to the non-negative function $C_1\mathrm{e}^{\beta v} - R_{d,M}(\mathrm{e}^v)\mathrm{e}^v$ (Remark 3.1); only the inequality $R_{d,M}(x) \le x^{\beta-1}$ is used, and no lower bound.

Real zeros. Zeros of the $\tilde{L}(\,\cdot\,,\xi)$ on the real segment $(\beta,1)$ are not excluded by hypothesis: they would give poles with positive residue, which Input 4 admits, and the conclusion excludes them. Real zeros of the twists in $(\beta,1)$ are excluded by (6.1). The header of the formal file notes that the classical forms of this argument assume that there are no real zeros, and names as related work M. Suzuki, *On variants of Chebyshev's conjecture* (2024), §§15.1–15.2 of [MV], and Landau's paper of 1905 on a theorem of Chebyshev; we have not compared the statements.

7 A good point in every window: proof of Theorem 3

The proof of Theorem 3 uses the analyticity of the transform on $\operatorname{Re} s \geq 1$ through the moments $\int_0^\infty v^i \mathrm{e}^{-3v} \mathcal{E}(v)\,\mathrm{d}v$, which are the derivatives of Φ at $s = 4$ up to sign.

Proposition 7.1 (moments of a polar function)**.** *Let $\mathcal{E}\colon \mathbb{R} \to \mathbb{R}$ and $\omega\colon \mathbb{C} \to \mathbb{C}$ be functions such that $\mathcal{E}$ is polar with residue function ω. Then there is a real number $\mathfrak{r}_0 > 3$ such that for every real number $\mathfrak{r}$ with $3 < \mathfrak{r} < \mathfrak{r}_0$ there is a real number v_* such that for every real $v_0 \geq v_*$:*

(i) $|\mathcal{E}(v)| \leq v_0\,\mathrm{e}^v$ *for every real $v \geq 0$;*

(ii) for every natural number i the function $v \mapsto v^i \mathrm{e}^{-3v}\mathcal{E}(v)$ is integrable on $(0,\infty)$, and

$$\Big|\int_0^\infty v^i\,\mathrm{e}^{-3v}\,\mathcal{E}(v)\,\mathrm{d}v\Big| \leq \frac{i!\,v_0}{\mathfrak{r}^i}.$$

Proof. Let C and Φ be as in Definition 2.8. Only the measurability of $\mathcal{E}$ and (P1), (P2), (P3) are used.

A disc of analyticity. The closed disc $|s-4| \leq 3$ lies in the half-plane $\operatorname{Re} s \geq 1$, and it contains the point $s = 1$. By (P3) the function $s \mapsto (s-1)\Phi(s)$, which vanishes at $s = 1$, is analytic at each of its points. The set of points at which a function is analytic is open and the disc is compact, so there is a real number $\mathfrak{r}_0 > 3$ such that $s \mapsto (s-1)\Phi(s)$ is analytic at every point of the open disc $|s-4| < \mathfrak{r}_0$. Let $3 < \mathfrak{r} < \mathfrak{r}_0$. Input 7, with $s_0 = 4$, $s_1 = 1$, $s_2 = 4 + \mathfrak{r}$ and the radius $\mathfrak{r}_0$, shows that the Taylor series of Φ at 4 converges absolutely at $4 + \mathfrak{r}$, beyond the point 1:

$$C_{\mathfrak{r}} = \sum_{i \geq 0} \frac{\mathfrak{r}^i\,|\Phi^{(i)}(4)|}{i!} < \infty.$$

Differentiation under the integral sign. We claim that for every natural number i and every $s \in \mathbb{C}$ with $\operatorname{Re} s > 2$ the function $v \mapsto (-v)^i \mathcal{E}(v) \mathrm{e}^{(1-s)v}$ is integrable on $(0,\infty)$, and

$$\Phi^{(i)}(s) = \int_0^\infty (-v)^i\,\mathcal{E}(v)\,\mathrm{e}^{(1-s)v}\,\mathrm{d}v. \tag{7.1}$$

For $i = 0$ this is Input 6(b) and (P2). Let the claim hold for i, let $\operatorname{Re} s > 2$, and choose $\Delta > 0$ with $2\Delta < \operatorname{Re} s - 2$. For $v > 0$ and $s' \in \mathbb{C}$ with $\operatorname{Re} s' > 2 + 2\Delta$,

$$\big|(-v)^{i+1}\mathcal{E}(v)\,\mathrm{e}^{(1-s')v}\big| \leq \frac{1}{\Delta}\,\big|(-v)^i\mathcal{E}(v)\,\mathrm{e}^{(1-(2+\Delta))v}\big|,$$

because $\Delta v \leq \mathrm{e}^{\Delta v}$ and $\Delta + 1 - \operatorname{Re} s' \leq -1 - \Delta$. The right side is integrable on $(0,\infty)$, by the claim for i at the point $2 + \Delta$, and it does not depend on s'. So the integral in (7.1) may be differentiated under the integral sign on the half-plane $\operatorname{Re} s' > 2 + 2\Delta$, which is a neighbourhood of s: its derivative at s is the integral for $i + 1$, which converges absolutely. Since the integral for i equals $\Phi^{(i)}$ on $\operatorname{Re} s' > 2$, this is the claim for $i + 1$.

Conclusion. At $s = 4$, (7.1) says that $v \mapsto v^i \mathrm{e}^{-3v}\mathcal{E}(v)$ is integrable on $(0,\infty)$ and that $\big|\int_0^\infty v^i \mathrm{e}^{-3v}\mathcal{E}(v)\,\mathrm{d}v\big| = |\Phi^{(i)}(4)| \leq i!\,C_{\mathfrak{r}}/\mathfrak{r}^i$. So (i) and (ii) hold for every $v_0 \geq v_* = \max(C, C_{\mathfrak{r}})$, (i) by (P1). □

LEAN `IsPolar.eventually_moment_le`

Proof of Theorem 3. Apply Proposition 7.1 to $(\mathcal{E}_1, \omega_1)$ and to $(\mathcal{E}_2, \omega_2)$, and choose a real number $\mathfrak{r}$ with $3 < \mathfrak{r} < 4$ that is below the bound $\mathfrak{r}_0$ of each of the two. Let v_* be so large that the conclusions (i) and (ii) hold for $\mathcal{E}_1$ and for $\mathcal{E}_2$ whenever $v_0 \geq v_*$, and that $v_* \geq 99/\log(\mathfrak{r}/3)$ and $v_* \geq 9$. Let $v_0 \geq v_*$ and $0 \leq X \leq \mathrm{e}^{v_0}$, and put $i = \lceil v_0^2/9 \rceil$. Since $v_0 + 1 \leq \mathrm{e}^{v_0}$ and $X \leq \mathrm{e}^{v_0}$,

$$v_0 + v_0 X + 1 \leq \mathrm{e}^{2v_0}. \tag{7.2}$$

Suppose, for a contradiction, that $\mathcal{E}_1(v) - X\mathcal{E}_2(v) > \mathrm{e}^{-v_0}$ for every v in the window $[v_0, v_0^2]$. Consider, for $v > 0$,

$$I(v) = \mathrm{e}^{7v_0 - \mathfrak{r}v} + \mathrm{e}^{2v_0 - v_0^2 - v} + \mathrm{e}^{-3v}\bigl(\mathcal{E}_1(v) - X\,\mathcal{E}_2(v) - \mathrm{e}^{-v_0}\bigr).$$

$I(v) \geq 0$ *for all* $v > 0$. In the window all three terms are positive. Outside it, by (i) for $\mathcal{E}_1$ and $\mathcal{E}_2$ and by (7.2), $|\mathcal{E}_1(v) - X\mathcal{E}_2(v) - \mathrm{e}^{-v_0}| \leq (v_0 + Xv_0 + 1)\mathrm{e}^{v} \leq \mathrm{e}^{2v_0 + v}$, so the third term is at least $-\mathrm{e}^{2v_0 - 2v}$. If $v < v_0$, then $7v_0 - \mathfrak{r}v \geq 2v_0 - 2v$, because $(\mathfrak{r} - 2)v < 2v_0$; so the first term compensates. If $v > v_0^2$, then $2v_0 - v_0^2 - v \geq 2v_0 - 2v$; so the second term compensates.

The contradiction. Multiply by v^i and integrate over $(0, \infty)$. By Input 6(a), and by (ii) for $\mathcal{E}_1$ and $\mathcal{E}_2$,

$$0 \leq \int_0^\infty v^i I(v)\,\mathrm{d}v \leq \frac{i!\,\mathrm{e}^{7v_0}}{\mathfrak{r}^{i+1}} + i!\,\mathrm{e}^{2v_0 - v_0^2} + \frac{i!\,(v_0 + Xv_0)}{\mathfrak{r}^i} - \frac{i!\,\mathrm{e}^{-v_0}}{3^{i+1}}.$$

With (7.2) and after division by $i!$,

$$\frac{\mathrm{e}^{-v_0}}{3^{i+1}} < \frac{\mathrm{e}^{7v_0}}{\mathfrak{r}^{i+1}} + \mathrm{e}^{2v_0 - v_0^2} + \frac{\mathrm{e}^{2v_0}}{\mathfrak{r}^i}. \tag{7.3}$$

But each term on the right is at most a third of the left side. Indeed $i \geq v_0^2/9$ and $v_0 \log(\mathfrak{r}/3) \geq 99$ give $(\mathfrak{r}/3)^i \geq \mathrm{e}^{11v_0}$, and $\mathrm{e}^{11v_0} \geq 3\mathrm{e}^{8v_0}$ and $\mathrm{e}^{11v_0} \geq 9\mathrm{e}^{3v_0}$: this settles the first and the third term. For the second term one needs $(i+2)\log 3 + 3v_0 \leq v_0^2$; it holds because $i + 2 \leq v_0^2/9 + 3$, $\log 3 < \frac{11}{10}$ and $v_0 \geq 9$. So the right side of (7.3) is at most the left side, a contradiction. Hence some $v_1 \in [v_0, v_0^2]$ has $\mathcal{E}_1(v_1) - X\mathcal{E}_2(v_1) \leq \mathrm{e}^{-v_0}$. □

LEAN `IsPolar.exists_window_sub_mul_le`

Remark 7.2 (what the window lemma replaces)**.** The weight $v^i\mathrm{e}^{-3v}$ has its mass near $v = i/3 \approx v_0^2/27$, inside the window, and the factor $\mathfrak{r}^{-i}$ with $\mathfrak{r} > 3$ in Proposition 7.1 says that the moments of a polar function are smaller, by a factor exponential in i, than those of a function of constant sign and size 1. So a polar function cannot stay above e^{-v_0} on a whole window. In the proof of the one-sided bound (Chapter I) the theorem is applied to $\mathcal{E}_1(v) = R_{d,N_0}(\mathrm{e}^v)$ and $\mathcal{E}_2(v) = R_{d,1}(\mathrm{e}^v)$, which are polar by Theorem 1, and e^{v_1} becomes the second scale of the data. A pointwise bound for these remainders, that is, a prime number theorem in progressions with a remainder term, is thus not needed; the header of the formal file names the work of Pintz and of Kaczorowski on sign changes of remainder terms as related, and we have not compared it.

8 Part II. The data, and what is taken from other units

From here on the note needs the vocabulary of the geometric part of the proof: the data, the rows and columns, the theta lifts. These objects belong to other units, and the chapters on those units define them. This section and the Settings of §§10 and 11 say what is used of them. The results of the present unit are then proved in full from the properties that are listed; the properties themselves are *taken for granted*, each with the unit that owns it, in the words of the reader's dossier, whose statements were compared with the Lean text.

Setting 8.1 (parameters and data; unit 152)**.** *Parameters* are a pair $P = (N_0, d)$: a positive multiple N_0 of 18480 and a prime number d with $d \equiv N_0/2 - 1 \pmod{N_0}$. *Admissible data* for P are a record D of unit 152. Among its components are three positive real numbers x, x_1, b, the *scales* (the record stores their logarithms), two natural numbers m and r, and a finite set $\mathrm{thick}(D)$ of infinite places of the field $E(D)$ defined below. To the parameters P and data D the following objects are attached.

The field and its places. $K = \mathbb{Q}(\sqrt{-d})$. The natural number $N_1(D)$ is a multiple of N_0 with the same prime divisors. The field $E(D)$ is K with the roots of unity of order $N_1(D)$ adjoined. Its infinite places form a principal homogeneous space under $\mathrm{Gal}(E(D)/K) \cong (\mathbb{Z}/N_1(D))^\times$; the isomorphism is restriction to the roots of unity, and it is onto because K is not contained in the field that they generate over $\mathbb{Q}$: the prime d ramifies in K and does not divide $N_1(D)$. A base place, fixed once by the artifact, identifies the places with this group, and so makes them a finite commutative group; $f(D)$ is their number. Reduction modulo N_0 gives each place τ a *class* in $(\mathbb{Z}/N_0)^\times$, multiplicatively in τ. For an integer ν and a place τ, the place $\nu \cdot \tau$ is the product of τ and the place identified with ν modulo $N_1(D)$ if ν is prime to $N_1(D)$, and $\nu \cdot \tau = \tau$ otherwise; if ν is prime to $N_1(D)$, the class of $\nu \cdot \tau$ is ν times the class of τ.

Tops and thick places. $\mathrm{tops}(D)$ is the set of the places of class 1 modulo N_0. Every place of $\mathrm{thick}(D)$ has class -1 modulo N_0. And $f(D) = \varphi(N_0) \cdot \#\mathrm{tops}(D)$.

Sizes. $k(D) = r + 1 - m$, $t(D) = 5r$, $a(D)$ is the least multiple of $N_1(D)$ that is at least $x\,b$, and $\mathrm{budget}(D) = f(D)\,a(D)\,(\log b)^3$.

Prime sums. The *nominal weight* of a place τ is $w_D(\tau) = a(D)/x$ if $\tau \in \mathrm{thick}(D)$ and $w_D(\tau) = a(D)/x_1$ otherwise; it is positive, and $\bar{w}_D$ is the mean of $\log w_D(\tau)$ over all $f(D)$ infinite places τ. For a real number z and a place τ,

$$\mathrm{Ask}_D(z, \tau) = \sum_{\nu=1}^{a(D)} \lambda_{d,1}(\nu) \left(\frac{z}{\nu} - w_D((-\nu) \cdot \tau) \right)_+ .$$

Periods, the cost of one direction, the level. $g(D)$ is the product of two primes of the data, and the *period term* is $\mathrm{per}_D = \log(g(D)\,\mathrm{rd}_{E(D)}/2\pi)$, with $\mathrm{rd}_{E(D)}$ the root discriminant of $E(D)$. For a natural number i the *jet size* is $\mathrm{jet}_D(i) = \log(i!) - i\,(\mathrm{cs}(d) - \mathrm{per}_D)$. The *cost of one direction* $\mathsf{U}(D)$ is a real number: a sum over all infinite places τ of a jet size minus the prime sum $\mathrm{Ask}_D(w_D(\tau), \tau)$; its formula is in Chapter III, and its value plays no role here. The *level* $N(D)$ is a prime number (unit 141). Finally (unit 145)

$$h_0(D) = m\Big(\sum_{\tau \in \mathrm{tops}(D)} (\mathrm{jet}_D(a(D)) - \mathrm{Ask}_D(a(D), \tau)) + k(D)\,\mathsf{U}(D) \Big) - \#\mathrm{tops}(D) \cdot a(D)\,\log N(D).$$

The formal text writes $\mathrm{cs}(d) - \mathrm{per}_D$ as $\log(\Omega/g(D))$ with the period $\Omega = \mathrm{e}^{\mathrm{cs}(d)} \cdot 2\pi/\mathrm{rd}_{E(D)}$. The next two boxes are what Part II takes from units 152 and 141 about sizes.

Input 8 (comparison of sizes; unit 152)**.** In Setting 8.1:

(S0) $a(D) \geq 1$, $x \leq a(D)$, $x_1 \leq a(D)$, $m\,k(D) \neq 0$, $b > 0$ and $\mathrm{budget}(D) > 0$;

(S1) $\#\mathrm{tops}(D) \cdot \big(m\,(1 + \frac{1}{2}\log a(D)) + a(D)\,(\mathrm{per}_D + \frac{15}{2}\log b)\big) \leq \mathrm{budget}(D)$;

(S2) if $|\mathrm{Ask}_D(z,\tau)| \leq 2\,a(D)\,|z|$ for all real z and all places τ, then $|h_{\mathrm{main}}(D)| + m\,|\mathrm{rem}(D)| \leq b^2 x^{99}$ (Definitions 9.1 and 9.3);

(S3) $x^{99} + 5\,\mathrm{budget}(D) \leq \log b \cdot \mathrm{budget}(D)$;

(S4) $x^{99} + x_1^2 b^2 + 4m^2\,t(D)\,x^{999} \leq \frac{1}{4}\,b^3$;

(S5) $m^2 \cdot 2\,t(D)\,x^{999} \leq 2\log b \cdot \mathrm{budget}(D)$;

(S6) $b \leq \log b \cdot \mathrm{budget}(D)$.

These are instances of one mechanism of unit 152. Every quantity attached to the data carries a bound of the form exp of a linear form in $\log x$, $\log x_1$, $\log b$ and $\log\log b$, found from the bounds of its factors, and two such bounds are compared through the conditions on the scales, among them $(\log b)^{100} \leq x$, $x^{10^6} \leq x_1$ and $x_1^{10^6} \leq b$. At (S2), (S3) and (S4) the source does not write out the inequality that it passes to this mechanism; the forms given here are those of the dossier, and the proofs below show that they are what is needed.

Input 9 (the level; unit 141)**.** In Setting 8.1: $N(D)$ is a prime number, and $\log N(D) \geq m\,(\bar{w}_D + \mathrm{per}_D) - \mathrm{per}_D - \frac{15}{2}\log b$.

The level is chosen, in a window of length $\sqrt{\log b}$, above this target.

9 The remainder of the data: Theorem 4

Definition 9.1 (the main amount)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Setting 8.1). Then $h_{\mathrm{main}}(D) = m\,k(D)\,\mathsf{U}(D)$.

LEAN `Data.mainHeight`

Definition 9.2 (the expected value of a prime sum)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Setting 8.1). Then

$$\mathrm{Ask}^{\mathrm{main}}(D) = a(D)\,\big(\log a(D) - 1 - \mathrm{cs}(d) - \bar{w}_D\big) = a(D)\,\big(\log a(D) + \kappa_{d,1} - \bar{w}_D\big),$$

the second form by Lemma 4.4.

LEAN `Data.mainAsk`

Definition 9.3 (the remainder of the data)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Setting 8.1). Then

$$\mathrm{rem}(D) = \sum_{\tau \in \mathrm{tops}(D)} \big(\mathrm{Ask}_D(a(D),\tau) - \mathrm{Ask}^{\mathrm{main}}(D)\big).$$

LEAN `Data.remainder`

Theorem 4 (the remainder of the data in terms of the remainders of Part I)**.** Let $P = (N_0, d)$ be parameters and D admissible data for P, with components x, x_1, b, m, r (Setting 8.1). Then

$$\operatorname{rem}(D) = a(D)\Big(\#\mathrm{thick}(D)\cdot\big(R_{d,N_0}(x) - R_{d,N_0}(x_1)\big) + \#\mathrm{tops}(D)\cdot R_{d,1}(x_1)\Big).$$

Proof. Write $a = a(D)$. By (S0), $a \geq 1$, $0 < x \leq a$ and $0 < x_1 \leq a$.

Step 1: counting. For every natural number ν,

$$\#\{\tau \in \mathrm{tops}(D) : (-\nu)\cdot\tau \in \mathrm{thick}(D)\} = \begin{cases} \#\mathrm{thick}(D) & \text{if } \nu \equiv 1 \pmod{N_0}, \\ 0 & \text{otherwise.} \end{cases} \tag{9.1}$$

Let $\nu \equiv 1 \pmod{N_0}$. Then ν is prime to N_0, hence to $N_1(D)$, which has the same prime divisors. So $\tau \mapsto (-\nu)\cdot\tau$ is a bijection of the set of places that multiplies the classes by $-\nu \equiv -1$: it maps $\mathrm{tops}(D)$ onto the set of the places of class -1 modulo N_0, which contains $\mathrm{thick}(D)$, and every thick place is met exactly once. Let $\nu \not\equiv 1 \pmod{N_0}$. If ν is prime to $N_1(D)$, the places $(-\nu)\cdot\tau$ with $\tau \in \mathrm{tops}(D)$ have class $-\nu \neq -1$, and none is thick. If ν is not prime to $N_1(D)$, then $(-\nu)\cdot\tau = \tau$ by the convention of Setting 8.1, and no place of $\mathrm{tops}(D)$ is thick, because the classes 1 and -1 modulo N_0 differ. This proves (9.1). By Definition 2.4, $\lambda_{d,N_0}(\nu)$ equals $\lambda_{d,1}(\nu)$ if $\nu \equiv 1 \pmod{N_0}$ and is 0 otherwise; so (9.1) gives, for every natural number ν,

$$\#\{\tau \in \mathrm{tops}(D) : (-\nu)\cdot\tau \in \mathrm{thick}(D)\}\cdot\lambda_{d,1}(\nu) = \#\mathrm{thick}(D)\cdot\lambda_{d,N_0}(\nu). \tag{9.2}$$

Step 2: the sum of the prime sums over the tops. For $\tau \in \mathrm{tops}(D)$ and $1 \leq \nu \leq a$ the weight $w_D((-\nu)\cdot\tau)$ is a/x if $(-\nu)\cdot\tau$ is thick and a/x_1 otherwise. Summing over τ and using (9.2),

$$\begin{aligned}\sum_{\tau\in\mathrm{tops}(D)} \mathrm{Ask}_D(a,\tau) = \#\mathrm{thick}(D)\sum_{\nu=1}^{a}\lambda_{d,N_0}(\nu)\Big(\big(\tfrac{a}{\nu}-\tfrac{a}{x}\big)_+ - \big(\tfrac{a}{\nu}-\tfrac{a}{x_1}\big)_+\Big) \\ + \#\mathrm{tops}(D)\sum_{\nu=1}^{a}\lambda_{d,1}(\nu)\big(\tfrac{a}{\nu}-\tfrac{a}{x_1}\big)_+.\end{aligned}$$

By Lemma 4.3, for $M \in \{N_0, 1\}$ and a real number z with $0 < z \leq a$, $\sum_{\nu=1}^{a}\lambda_{d,M}(\nu)(\frac{a}{\nu}-\frac{a}{z})_+ = a\big(R_{d,M}(z) + \log z/\varphi(M) + \kappa_{d,M}\big)$. We use it for $M = N_0$ at $z = x$ and $z = x_1$, where the constant κ_{d,N_0} drops out of the difference, and for $M = 1$ at $z = x_1$, where $\varphi(1) = 1$:

$$\begin{aligned}\sum_{\tau\in\mathrm{tops}(D)} \mathrm{Ask}_D(a,\tau) = a\Big(\#\mathrm{thick}(D)\big(R_{d,N_0}(x) - R_{d,N_0}(x_1)\big) + \#\mathrm{tops}(D)\,R_{d,1}(x_1)\Big) \\ + a\Big(\#\mathrm{thick}(D)\,\frac{\log x - \log x_1}{\varphi(N_0)} + \#\mathrm{tops}(D)\,(\log x_1 + \kappa_{d,1})\Big).\end{aligned}$$

Step 3: the expected value. Since $\#\mathrm{thick}(D)$ places have weight a/x and the other $f(D) - \#\mathrm{thick}(D)$ have weight a/x_1, $\log a - \bar{w}_D = \log x_1 + \frac{\#\mathrm{thick}(D)}{f(D)}(\log x - \log x_1)$. With $f(D) = \varphi(N_0)\cdot\#\mathrm{tops}(D)$ and Definition 9.2,

$$\#\mathrm{tops}(D)\cdot\mathrm{Ask}^{\mathrm{main}}(D) = a\Big(\#\mathrm{thick}(D)\,\frac{\log x - \log x_1}{\varphi(N_0)} + \#\mathrm{tops}(D)\,(\log x_1 + \kappa_{d,1})\Big).$$

Step 4. By Definition 9.3, $\mathrm{rem}(D) = \sum_{\tau \in \mathrm{tops}(D)} \mathrm{Ask}_D(a,\tau) - \#\mathrm{tops}(D) \cdot \mathrm{Ask}^{\mathrm{main}}(D)$, and Steps 2 and 3 give the claim: the terms $\log x$, $\log x_1$ and $\kappa_{d,1}$ cancel. □

LEAN `Data.remainder_eq`

Step 1 is the place where the progression 1 modulo N_0 enters the proof: the thick places sit in one class, and the tops are the stabiliser of that class. The convention for the integers ν that are not prime to $N_1(D)$ does not affect the prime sums: for such ν the weight $\lambda_{d,1}(\nu)$ is 0, because every prime that divides $N_1(D)$ splits in K (unit 152).

Proposition 9.4 (the level pays the excess)**.** *Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Setting 8.1). Then*

$$h_0(D) \le h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \mathrm{budget}(D).$$

Proof. Write $a = a(D)$. By the definitions of $h_0(D)$, $h_{\mathrm{main}}(D)$ and $\mathrm{rem}(D)$,

$$h_0(D) = h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \#\mathrm{tops}(D) \cdot \Big(m\,(\mathrm{jet}_D(a) - \mathrm{Ask}^{\mathrm{main}}(D)) - a\,\log N(D) \Big). \tag{9.3}$$

The excess of one row. By the definitions of the jet size and of $\mathrm{Ask}^{\mathrm{main}}(D)$, in which the constant $\mathrm{cs}(d)$ cancels, $\mathrm{jet}_D(a) - \mathrm{Ask}^{\mathrm{main}}(D) = \log(a!) - a\log a + a + a\,(\bar{w}_D + \mathrm{per}_D)$. Stirling's bound $\log(a!) \le a\log a - a + 1 + \frac{1}{2}\log a$, valid for $a \ge 1$, gives

$$\mathrm{jet}_D(a) - \mathrm{Ask}^{\mathrm{main}}(D) \le a\,(\bar{w}_D + \mathrm{per}_D) + 1 + \tfrac{1}{2}\log a.$$

The level. By Input 9, $a \log N(D) \ge a\,m\,(\bar{w}_D + \mathrm{per}_D) - a\,(\mathrm{per}_D + \frac{15}{2}\log b)$. So the term $m\,a\,(\bar{w}_D + \mathrm{per}_D)$ cancels in the bracket of (9.3), which is at most $m\,(1 + \frac{1}{2}\log a) + a\,(\mathrm{per}_D + \frac{15}{2}\log b)$. The claim follows from (S1). □

LEAN `Data.heightPerRow_le`

The number $h_0(D)$ will bound the logarithm of the size of a chain of m theta lifts of a short column (Input 12). The proposition says that the level $N(D)$, whose logarithm is subtracted in $h_0(D)$, has been chosen so that it cancels the excess of size over expected divisibility of the m lifts; what remains is the main amount, less m times the remainder of the data.

Lemma 9.5 (a crude bound)**.** *Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Setting 8.1). Then*

$$|h_{\mathrm{main}}(D)| + m \cdot |\mathrm{rem}(D)| \le b^2\, x^{99}.$$

Proof. For every real number z and every place τ, $|\mathrm{Ask}_D(z,\tau)| \le 2\,a(D)\,|z|$: the sum has $a(D)$ terms, and $0 \le \lambda_{d,1}(\nu)\,(z/\nu - w)_+ \le 2\nu \cdot |z|/\nu$ for every weight $w \ge 0$, by Lemma 4.1. The claim is then (S2). In the formal text the comparison of sizes also uses that $|\,\mathrm{cs}(d)|$ is at most a constant of the parameters, which the conditions on the scales make negligible. □

LEAN `Data.abs_mainHeight_add_remainder_le`

The bound is far from sharp, and it is only used to pay for a small number of missing dimensions in the proof of the main inequality. To see that there is room (this is not the formal argument): unit 152 has $m \le 2\sqrt{x}$, $r \le 3x^5$ and $f(D) \le x^{11}(\log b)^{1/5}$ up to a constant of the parameters, and $a(D)$ is about xb; so the $f(D)$ prime sums in $\mathsf{U}(D)$, each at most $2a(D)^2/x$, give $|h_{\mathrm{main}}(D)|$ the order $x^{18}b^2$ at most, and $m\,|\mathrm{rem}(D)|$ has the order $x^{14}b^2$ at most.

10 Theorems A and B

Setting 10.1 (forms and lifts; units 102, 140, 141, 143, 145, 147, 148)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r, as in Setting 8.1. Other units attach to D the following objects.

Columns (unit 145). $\mathrm{Col}(D)$ is a finite-dimensional complex vector space of algebraic modular forms on a definite unitary group of rank $k(D)$ over $E(D)$; its complex dimension $\dim \mathrm{Col}(D)$ is a different number from the rank $k(D)$, and both occur below. The *ramifying operator* is a linear map $\mathrm{ram}_D \colon \mathrm{Col}(D) \to \mathrm{Col}(D)$, and its image $\mathrm{Col}^{\mathrm{ram}}(D)$ is the space of *ramified columns*.

Rows (units 140, 141). $\mathsf{G}(D)$ is a finite group. $\mathrm{PF}(D)$ is a complex vector space of cusp forms on an indefinite unitary group of rank r over $E(D)$, the *forms of principal level*, on which $\mathsf{G}(D)$ acts linearly. The space of *rows* $\mathrm{Row}(D) \subseteq \mathrm{PF}(D)$ is the image of a fixed idempotent of the group algebra of $\mathsf{G}(D)$; it is finite-dimensional. For $\gamma \in \mathsf{G}(D)$ the linear map $\varpi_D(\gamma) \colon \mathrm{PF}(D) \to \mathrm{Row}(D)$ translates a form by γ and applies $\#\mathsf{G}(D)$ times the idempotent.

Poincaré series (unit 148). A linear map $\mathrm{Poin}_D \colon \mathrm{Col}(D) \to \mathrm{PF}(D)$.

Twists and lifts (units 141, 143, 147). A *twist* of D is a character ϑ of a certain kind, with a finite set $Q(\vartheta)$ of primes of $E(D)$ where it ramifies; an *m-fold twist* is a twist whose powers $\vartheta^2, \dots, \vartheta^m$ are twists with the same set; the trivial character 1 is an m-fold twist with $Q(1) = \emptyset$. A prime number ℓ is *prime to* ϑ if it is prime to the norms of the primes in $Q(\vartheta)$. For a twist ϑ, the *chain of lifts* is a linear map $\Theta^{\flat}_{D,\vartheta} \colon \mathrm{PF}(D) \to \mathcal{A}_{D,\vartheta}$, the composite of m theta lifts, into a finite-dimensional complex vector space $\mathcal{A}_{D,\vartheta}$ of algebraic modular forms on a definite unitary group, which carries a positive definite hermitian product. For an m-fold twist ϑ, $\Theta_{D,\vartheta} \colon \mathrm{Row}(D) \to \mathcal{A}_{D,\vartheta}$ is the restriction of $\Theta^{\flat}_{D,\vartheta}$ to the rows, and $\mathfrak{z}_D(\vartheta) = \det(\Theta^*_{D,\vartheta}\Theta_{D,\vartheta})$.

Conjugates and sizes (unit 102). The columns and the elements of the spaces $\mathcal{A}_{D,\vartheta}$ are functions with values in complex vector spaces that have a rational structure and a norm; so for $\sigma \in \mathrm{Aut}(\mathbb{C})$ a form F has a conjugate $\sigma \circ F$. We say that F is *pointwise at most* e^B *at* σ, for a real number B, if every value of $\sigma \circ F$ has squared norm at most e^B. For $F, F_1, \dots, F_n$ in $\mathcal{A}_{D,\vartheta}$, $\|F\|^2_\sigma$ is the Petersson norm of $\sigma \circ F$, a finite sum over classes of squared norms of values, and $\mathrm{covol}^2_\sigma(F_1, \dots, F_n)$ is the absolute value of the determinant of the matrix of Petersson products of the $\sigma \circ F_i$.

Integrality (unit 102). For a prime number ℓ and a ring homomorphism $j \colon \mathbb{C} \to \mathbb{C}_\ell$, O_j is the ring of the complex numbers H with $|j(H)|_\ell \leq 1$. A column, or an element of some $\mathcal{A}_{D,\vartheta}$, is *$j$-integral* if all its values are, for a lattice fixed in unit 102; the j-integral elements form an O_j-module, and if F is j-integral and $|j(H)|_\ell \leq 1$ for a complex number H, then HF is j-integral. A column is *integral* if it is j-integral for every prime ℓ and every $j \colon \mathbb{C} \to \mathbb{C}_\ell$.

Input 10 (the seesaw identity; unit 141)**.** In Settings 8.1 and 10.1 there is a non-zero complex number H such that for every twist ϑ of D there is a good datum Ψ for ϑ with

$$\Theta^{\flat}_{D,\vartheta}(\mathrm{Poin}_D(H\,\psi)) = \mathrm{Ch}_D(\vartheta,\Psi)(\psi) \qquad \text{for every } \psi \in \mathrm{Col}^{\mathrm{ram}}(D).$$

Here a *good datum* for ϑ is a notion of unit 145, and $\mathrm{Ch}_D(\vartheta,\Psi)\colon \mathrm{Col}(D) \to \mathcal{A}_{D,\vartheta}$ is the chain of m theta lifts between definite spaces that Ψ defines (unit 147). The formal text fixes one such number H, by choice; we write $\mathrm{cst}^{\mathrm{see}}_D$ for it.

The identity moves the lifts of Poincaré series to the definite side, where sizes and divisibility are computed; it is the subject of Chapter V.

Definition 10.2 (the scaled inclusion)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1). The linear map $\mathrm{inc}(D)\colon \mathrm{Col}^{\mathrm{ram}}(D) \to \mathrm{Col}(D)$ is the inclusion multiplied by the constant $\mathrm{cst}^{\mathrm{see}}_D$ of Input 10.

LEAN `Data.scaledInclusion`

Definition 10.3 (the Poincaré maps)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1), and let $\gamma \in \mathsf{G}(D)$. The linear map $\mathcal{P}_D(\gamma)\colon \mathrm{Col}^{\mathrm{ram}}(D) \to \mathrm{Row}(D)$ is the composite $\varpi_D(\gamma) \circ \mathrm{Poin}_D \circ \mathrm{inc}(D)$; its value at a ramified column ψ is written $\mathcal{P}_D(\gamma)\psi$.

LEAN `Data.projectedPoincare`

Definition 10.4 (integral ramified columns)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1). Then $\mathrm{Col}^{\mathrm{ram}}_{\mathrm{int}}(D)$ is the set of the ramified columns $\psi \in \mathrm{Col}^{\mathrm{ram}}(D)$ that are integral: j-integral for every prime number ℓ and every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_\ell$.

LEAN `Data.integralRamified`

Definition 10.5 (the index of a family of rows)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1). Let n be a natural number, $y = (y_1, \dots, y_n)$ a family of rows in $\mathrm{Row}(D)$, and δ a real number. We say that y has D-index at most δ, and write $\mathrm{ind}_D(y) \le \delta$, if there are real numbers η_ℓ, $\ell \in \mathbb{N}$, with $\sum_{\ell \in J} \eta_\ell \le \delta$ for every finite set $J \subset \mathbb{N}$, such that for every prime number ℓ, every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_\ell$ and every m-fold twist ϑ of D to which ℓ is prime, there is an $n \times n$ matrix $u = (u_{ii'})$ with entries in O_j such that $|j(\det u)|_\ell \ge \mathrm{e}^{-\eta_\ell}$ and such that $\Theta_{D,\vartheta}(\sum_{i'} u_{ii'}\, y_{i'})$ is j-integral for $i = 1, \dots, n$.

LEAN `Data.IndexLe`

The index bounds, prime by prime and for all twists at once, the denominators of the lifts of the family: after a change of the family by a matrix of small determinant, the lifts are integral.

Input 11 (short integral columns span; unit 145)**.** In Settings 8.1 and 10.1, $\mathrm{Col}^{\mathrm{ram}}(D)$ is spanned over $\mathbb{C}$ by the ramified columns that are integral and pointwise at most $\mathrm{e}^{\mathrm{budget}(D)}$ at every $\sigma \in \mathrm{Aut}(\mathbb{C})$.

Input 12 (the size of the chain; units 145, 150)**.** In Settings 8.1 and 10.1, let $\mathrm{nonsplit}(D)$ be the set of the prime numbers $\ell < x_1$ with $\chi_d(\ell) \neq 1$, and let $\mathrm{gain}_D(\ell)$, for a natural number ℓ, be the real number that unit 150 calls the *gain* at ℓ: the divisibility by ℓ that is asked of a chain of lifts. Let Ψ be a good datum for the trivial twist, $\sigma \in \mathrm{Aut}(\mathbb{C})$, $\psi \in \mathrm{Col}^{\mathrm{ram}}(D)$ and B a real number. If ψ is pointwise at most e^B at σ, then $\mathrm{Ch}_D(1,\Psi)(\psi)$ is pointwise at most

$$\exp\Bigl(B + h_0(D) + 2\sum_{\ell \in \mathrm{nonsplit}(D)} \mathrm{gain}_D(\ell)\,\log\ell + \mathrm{budget}(D)\Bigr) \quad \text{at } \sigma.$$

Input 13 (passing to the rows; unit 143)**.** In Settings 8.1 and 10.1, let $F \in \mathrm{PF}(D)$ and $\gamma \in \mathsf{G}(D)$.
(a) Let $\sigma \in \mathrm{Aut}(\mathbb{C})$ and let B be a real number. If $\Theta^{\flat}_{D,1}(F)$ is pointwise at most e^B at σ, then $\|\Theta_{D,1}(\varpi_D(\gamma)F)\|^2_\sigma \leq \exp(x^{99} + B)$.
(b) Let ϑ be a twist of D, ℓ a prime number, $j\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism and H a complex number. If $H \cdot \Theta^{\flat}_{D,\vartheta}(F)$ is j-integral, then so is $H \cdot \Theta^{\flat}_{D,\vartheta}(\varpi_D(\gamma)F)$.

Input 14 (the divisibility of the chain; units 145, 150)**.** In Settings 8.1 and 10.1, unit 145 defines for every natural number ℓ a real number $\mathrm{err}_D(\ell)$, the *allowed loss* at ℓ, with these properties.
(a) $\mathrm{err}_D(\ell) = 0$ unless $\ell \in \mathrm{nonsplit}(D)$ or $\ell = N(D)$; and $\sum_{\ell \in J} \mathrm{err}_D(\ell)\log\ell \leq \mathrm{budget}(D)$ for every finite set $J \subset \mathbb{N}$.
(b) Let ℓ be a prime number, $j\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism, and e an integer with $e < \mathrm{gain}_D(\ell) - \mathrm{err}_D(\ell) + 1$ if $\ell \in \mathrm{nonsplit}(D)$, and $e < -\mathrm{err}_D(\ell) + 1$ otherwise. Then there are a natural number $i_0 \leq \mathrm{err}_D(\ell) \cdot \dim \mathrm{Col}(D)$ and an O_j-submodule $\mathcal{S}$ of $\mathrm{Col}(D)$ such that: every finite family $\psi_1, \dots, \psi_n$ of j-integral columns admits an $n \times n$ matrix u over O_j whose determinant divides ℓ^{i_0} in O_j and for which all $\sum_{i'} u_{ii'}\psi_{i'}$ lie in $\mathcal{S}$; and $\ell^{-e} \cdot \mathrm{Ch}_D(\vartheta,\Psi)(\psi)$ is j-integral for every twist ϑ of D to which ℓ is prime, every good datum Ψ for ϑ and every $\psi \in \mathcal{S} \cap \mathrm{Col}^{\mathrm{ram}}(D)$.

Input 15 (the index of a span; unit 149)**.** In Settings 8.1 and 10.1, let ℓ be a prime number, $j\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism, i_0 a natural number and q a rational number. Let $\mathcal{M} \subseteq \mathrm{Col}^{\mathrm{ram}}(D)$ and $\mathcal{N} \subseteq \mathrm{Row}(D)$ be O_j-submodules. Assume that for every $\gamma \in \mathsf{G}(D)$ every finite family $\psi_1, \dots, \psi_n$ in $\mathcal{M}$ admits an $n \times n$ matrix u over O_j whose determinant divides ℓ^{i_0} and for which all $q\,\mathcal{P}_D(\gamma)(\sum_{i'} u_{ii'}\psi_{i'})$ lie in $\mathcal{N}$. Then for every finite set $\mathcal{T} \subseteq \mathsf{G}(D)$, every finite family $y_1, \dots, y_n$ in the O_j-span of $\mathcal{N}$ and of the rows $q\,\mathcal{P}_D(\gamma)\psi$ with $\gamma \in \mathcal{T}$, $\psi \in \mathcal{M}$, admits an $n \times n$ matrix u over O_j whose determinant divides $\ell^{i_0 \cdot \#\mathcal{T}}$ and for which all $\sum_{i'} u_{ii'}y_{i'}$ lie in $\mathcal{N}$.

A special case of a lemma on modules over a commutative ring: the index of a sum of images is at most the product of the indices.

Lemma 10.6 (a rational number with prescribed valuations)**.** *Let J be a finite set of natural numbers and $e\colon \mathbb{N} \to \mathbb{Z}$, $\ell \mapsto e_\ell$, a function. Assume that every element*

of J is a prime number and that $e_\ell = 0$ for every $\ell \notin J$. Then there is a rational number q with $q > 0$, $\log q = \sum_{\ell \in J} e_\ell \log \ell$, and $|q|_\ell = |\ell|_\ell^{e_\ell}$ for every prime number ℓ, where $|\cdot|_\ell$ is the absolute value of $\mathbb{C}_\ell$.

Proof. Take $q = \prod_{\ell \in J} \ell^{e_\ell}$. For a prime $\ell \in J$ the other factors are ℓ-adic units; for a prime $\ell \notin J$ all factors are, and $e_\ell = 0$. □

LEAN `exists_rat_log_eq_and_padic_norm_eq`

Theorem A (short forms)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1). There is a rational number $q > 0$ with the following two properties.
(a) Size. There is a subset S of $\mathrm{Col}^{\mathrm{ram}}_{\mathrm{int}}(D)$ that spans $\mathrm{Col}^{\mathrm{ram}}(D)$ over $\mathbb{C}$, such that for all $\psi \in S$, all $\gamma \in \mathsf{G}(D)$ and all $\sigma \in \mathrm{Aut}(\mathbb{C})$,

$$\|\Theta_{D,1}(q\,\mathcal{P}_D(\gamma)\psi)\|_\sigma^2 \le \exp(h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \log b \cdot \mathrm{budget}(D)).$$

(b) Index. For every finite set $\mathcal{T} \subseteq \mathsf{G}(D)$, every natural number n and every family $y = (y_1, \dots, y_n)$ of rows, each of the form $q\,\mathcal{P}_D(\gamma)\psi$ with $\gamma \in \mathcal{T}$ and $\psi \in \mathrm{Col}^{\mathrm{ram}}_{\mathrm{int}}(D)$: y has D-index at most $\#\mathcal{T} \cdot \dim \mathrm{Col}(D) \cdot \mathrm{budget}(D)$.

Proof. The number q. Let $J = \mathrm{nonsplit}(D) \cup \{N(D)\}$, a finite set of primes (Input 9), and for a natural number ℓ let

$$e_\ell = \lfloor \mathrm{err}_D(\ell) - \mathrm{gain}_D(\ell) \rfloor \ \text{ if } \ell \in \mathrm{nonsplit}(D), \qquad e_\ell = \lfloor \mathrm{err}_D(\ell) \rfloor \ \text{ otherwise.}$$

Then $e_\ell = 0$ for $\ell \notin J$ by Input 14(a). Let q be the rational number of Lemma 10.6: $q > 0$, $\log q = \sum_{\ell \in J} e_\ell \log \ell$, and $|q|_\ell = |\ell|_\ell^{e_\ell}$ for every prime ℓ. For every twist ϑ choose a good datum Ψ_ϑ as in Input 10. By Definitions 10.2 and 10.3, for $\gamma \in \mathsf{G}(D)$, $\psi \in \mathrm{Col}^{\mathrm{ram}}(D)$ and an m-fold twist ϑ,

$$\mathcal{P}_D(\gamma)\psi = \varpi_D(\gamma)(\mathrm{Poin}_D(\mathrm{cst}^{\mathrm{see}}_D\ \psi)), \qquad \Theta^{\flat}_{D,\vartheta}(\mathrm{Poin}_D(\mathrm{cst}^{\mathrm{see}}_D\ \psi)) = \mathrm{Ch}_D(\vartheta, \Psi_\vartheta)(\psi). \tag{10.1}$$

(a). Let S be the set of the ramified columns that are integral and pointwise at most $\mathrm{e}^{\mathrm{budget}(D)}$ at every $\sigma \in \mathrm{Aut}(\mathbb{C})$. Then $S \subseteq \mathrm{Col}^{\mathrm{ram}}_{\mathrm{int}}(D)$, and S spans $\mathrm{Col}^{\mathrm{ram}}(D)$ by Input 11. Let $\psi \in S$, $\gamma \in \mathsf{G}(D)$ and $\sigma \in \mathrm{Aut}(\mathbb{C})$. Since $\sigma(q) = q$, the column $q\psi$ is pointwise at most $q^2\mathrm{e}^{\mathrm{budget}(D)} = \exp(2\log q + \mathrm{budget}(D))$ at σ. By (10.1) and Input 12, $\Theta^{\flat}_{D,1}(\mathrm{Poin}_D(\mathrm{cst}^{\mathrm{see}}_D\ q\psi)) = \mathrm{Ch}_D(1, \Psi_1)(q\psi)$ is pointwise at most $\exp(2\log q + \mathrm{budget}(D) + h_0(D) + 2\sum_{\ell \in \mathrm{nonsplit}(D)} \mathrm{gain}_D(\ell)\log\ell + \mathrm{budget}(D))$ at σ, and by Input 13(a) the number $\|\Theta_{D,1}(q\,\mathcal{P}_D(\gamma)\psi)\|_\sigma^2$ is at most exp of x^{99} plus this exponent. Now

$$\begin{aligned} 2\log q = 2\sum_{\ell \in J} e_\ell \log \ell &\le 2\sum_{\ell \in J} \mathrm{err}_D(\ell)\log\ell - 2\sum_{\ell \in \mathrm{nonsplit}(D)} \mathrm{gain}_D(\ell)\log\ell \\ &\le 2\,\mathrm{budget}(D) - 2\sum_{\ell \in \mathrm{nonsplit}(D)} \mathrm{gain}_D(\ell)\log\ell, \end{aligned}$$

by Input 14(a). The gains cancel: this is what q is for. With $h_0(D) \le h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \mathrm{budget}(D)$ (Proposition 9.4) the exponent is at most $h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + x^{99} + 5\,\mathrm{budget}(D)$, and (S3) gives (a).

(b). Let $\mathcal{T}$, n and y be as in (b), and put $\eta_\ell = \#\mathcal{T} \cdot \dim \mathrm{Col}(D) \cdot \mathrm{err}_D(\ell)\log\ell$ for $\ell \in \mathbb{N}$. Then $\sum_{\ell \in J'} \eta_\ell \le \#\mathcal{T} \cdot \dim \mathrm{Col}(D) \cdot \mathrm{budget}(D)$ for every finite set $J' \subset \mathbb{N}$,

by Input 14(a). Let ℓ be a prime number, $j\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism and ϑ an m-fold twist to which ℓ is prime. The integer $e = -e_\ell$ satisfies the hypothesis of Input 14(b), because $-\lfloor z \rfloor < -z + 1$ for real z. Let i_0 and $\mathcal{S}$ be as given there, and let $\mathcal{M}$ be the O_j-module of the j-integral ramified columns, $\mathcal{N}$ the O_j-module of the rows y' for which $\Theta_{D,\vartheta}(y')$ is j-integral. We check the hypothesis of Input 15. Let $\gamma \in \mathsf{G}(D)$ and let $\psi_1, \dots, \psi_n$ be in $\mathcal{M}$. Input 14(b) gives a matrix u over O_j whose determinant divides ℓ^{i_0} such that every $\psi_i' = \sum_{i'} u_{ii'}\psi_{i'}$ lies in $\mathcal{S} \cap \mathrm{Col}^{\mathrm{ram}}(D)$ and $\ell^{e_\ell}\,\mathrm{Ch}_D(\vartheta, \Psi_\vartheta)(\psi_i')$ is j-integral. Since $|q|_\ell = |\ell^{e_\ell}|_\ell$, also $q\,\mathrm{Ch}_D(\vartheta, \Psi_\vartheta)(\psi_i') = q\,\Theta^\flat_{D,\vartheta}(\mathrm{Poin}_D(\mathrm{cst}_D^{\mathrm{see}}\,\psi_i'))$ is j-integral, by (10.1); and then so is $q\,\Theta^\flat_{D,\vartheta}(\varpi_D(\gamma)\,\mathrm{Poin}_D(\mathrm{cst}_D^{\mathrm{see}}\,\psi_i')) = \Theta_{D,\vartheta}(q\,\mathcal{P}_D(\gamma)\psi_i')$, by Input 13(b). So $q\,\mathcal{P}_D(\gamma)\psi_i' \in \mathcal{N}$. Each y_i is of the form $q\,\mathcal{P}_D(\gamma)\psi$ with $\gamma \in \mathcal{T}$ and $\psi \in \mathrm{Col}^{\mathrm{ram}}_{\mathrm{int}}(D) \subseteq \mathcal{M}$. So Input 15 gives an $n \times n$ matrix u over O_j whose determinant divides $\ell^{i_0 \cdot \#\mathcal{T}}$ in O_j, with $\Theta_{D,\vartheta}(\sum_{i'} u_{ii'}y_{i'})$ j-integral for all i. Finally $|j(\det u)|_\ell \geq |\ell|_\ell^{i_0 \cdot \#\mathcal{T}} = \exp(-i_0 \cdot \#\mathcal{T} \cdot \log \ell) \geq \mathrm{e}^{-\eta_\ell}$, because $i_0 \leq \mathrm{err}_D(\ell) \cdot \dim \mathrm{Col}(D)$. This is Definition 10.5. □

LEAN `Data.short_forms`

Input 16 (columns and rows exist; units 141, 148)**.** In Settings 8.1 and 10.1: $\mathrm{Col}(D) \neq 0$ and $\mathrm{Row}(D) \neq 0$.

Input 17 (the filling theorem, and few translates; units 148, 135)**.** In Settings 8.1 and 10.1:
(a) For every non-zero complex number H the family of linear maps $\varpi_D(\gamma) \circ \mathrm{Poin}_D \circ (H \cdot \mathrm{ram}_D)\colon \mathrm{Col}(D) \to \mathrm{Row}(D)$, $\gamma \in \mathsf{G}(D)$, is *spread with constant* b^{-2}: for every subspace W of $\mathrm{Row}(D)$ there is $\gamma \in \mathsf{G}(D)$ such that the preimage of W under the map of index γ has dimension at most $(\frac{1}{2}(1 + \dim W / \dim \mathrm{Row}(D)) + b^{-2}) \cdot \dim \mathrm{Col}(D)$.
(b) If a family of linear maps from $\mathrm{Col}(D) \neq 0$ to $\mathrm{Row}(D)$, indexed by $\mathsf{G}(D)$, is spread with constant b^{-2}, then there is a finite set $\mathcal{T} \subseteq \mathsf{G}(D)$ with $\#\mathcal{T} \cdot \dim \mathrm{Col}(D) \leq 5 \dim \mathrm{Row}(D) \cdot \log(1 + b^2)$ such that the sum of the images of the maps of index $\gamma \in \mathcal{T}$ has dimension at least $(1 - 4b^{-2}) \dim \mathrm{Row}(D)$.

(a) is the filling theorem of unit 148, the subject of Chapter VI. (b) is a special case of a lemma of unit 135 on families of linear maps between finite-dimensional spaces, proved by a greedy choice of translates.

Theorem B (enough forms)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1). Then $\dim \mathrm{Col}(D) > 0$ and $\dim \mathrm{Row}(D) > 0$, and there is a finite set $\mathcal{T} \subseteq \mathsf{G}(D)$ with

$$\#\mathcal{T} \cdot \dim \mathrm{Col}(D) \leq 5 \dim \mathrm{Row}(D) \cdot \log(1 + b^2) \qquad \text{and}$$
$$\left(1 - \frac{4}{b^2}\right) \dim \mathrm{Row}(D) \leq \dim \sum_{\gamma \in \mathcal{T}} \mathcal{P}_D(\gamma)(\mathrm{Col}^{\mathrm{ram}}(D)).$$

Proof. The dimensions are positive by Input 16. Apply Input 17(a) with $H = \mathrm{cst}_D^{\mathrm{see}}$, and then (b), which is allowed because $b > 0$ by (S0): there is a finite set $\mathcal{T} \subseteq \mathsf{G}(D)$ with the first inequality, such that the images of

the maps $\varpi_D(\gamma) \circ \mathrm{Poin}_D \circ (\mathrm{cst}_D^{\mathrm{see}} \cdot \mathrm{ram}_D)$, $\gamma \in \mathcal{T}$, span dimension at least $(1 - 4/b^2) \dim \mathrm{Row}(D)$. For a column ψ_0 the element $\mathrm{ram}_D(\psi_0)$ is a ramified column, and $\varpi_D(\gamma)\,\mathrm{Poin}_D(\mathrm{cst}_D^{\mathrm{see}}\,\mathrm{ram}_D(\psi_0)) = \mathcal{P}_D(\gamma)\,\mathrm{ram}_D(\psi_0)$ by Definitions 10.2 and 10.3. So each of these images lies in $\mathcal{P}_D(\gamma)(\mathrm{Col}^{\mathrm{ram}}(D))$, and the second inequality follows. □

LEAN `Data.enough_forms`

11 Theorem C, and the family given by A and B

Setting 11.1 (heights and fit families; units 135, 138)**.** Let P and D be as in Settings 8.1 and 10.1. Families of complex numbers and of twists are indexed by the pairs (ℓ, ι) of a prime number ℓ and a field isomorphism $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$ onto an algebraic closure of the field of ℓ-adic numbers, with its absolute value $|\cdot|_\ell$. A family $Z = (Z_{\ell,\iota})$ of complex numbers has *height at most* h, for a real number h, if there are a non-zero complex number H, a real number α and real numbers η_ℓ, $\ell \in \mathbb{N}$, such that $|\sigma(H)| \le \mathrm{e}^{\alpha}$ for all $\sigma \in \mathrm{Aut}(\mathbb{C})$, $|\iota(H\,Z_{\ell,\iota})|_\ell \le \mathrm{e}^{\eta_\ell}$ for all pairs (ℓ, ι), and $\alpha + \sum_{\ell<i,\ \ell \text{ prime}} \eta_\ell \le h$ for all sufficiently large natural numbers i (unit 135). A family $\theta = (\theta_{\ell,\iota})$ of m-fold twists of D may be *fit for* D; this property is defined in unit 138 and bounds, for each ℓ, the congruences of the lifts at the twists $\theta_{\ell,\iota}$. Of its definition we use only that ℓ is prime to $\theta_{\ell,\iota}$ for every pair (ℓ, ι); otherwise it enters through Inputs 20, 21 and 22.

Input 18 (heights; unit 135)**.** For families Z, Z' of complex numbers indexed by the pairs (ℓ, ι) and real numbers h, h':
(a) if Z has height at most h and Z' has height at most h', then the family of the products $Z_{\ell,\iota} Z'_{\ell,\iota}$ has height at most $h + h'$; the same holds for finite products, and the family of the n-th powers of Z has height at most $n\,h$;
(b) if Z has height at most h, $h \le h'$, and $|\iota(Z'_{\ell,\iota})|_\ell \le |\iota(Z_{\ell,\iota})|_\ell$ for all pairs, then Z' has height at most h';
(c) if the constant family 1 has height at most h, then $h \ge 0$.
(c) is the product formula, applied to the norm of the auxiliary number H. Chapter IV.

Input 19 (fit families exist; unit 138)**.** In Settings 8.1, 10.1 and 11.1 there is a family $\theta = (\theta_{\ell,\iota})$ of m-fold twists of D that is fit for D.
The subject of Chapter VIII.

Input 20 (the volume of the chain; units 143, 147)**.** In Settings 8.1, 10.1 and 11.1, say that a complex-valued function $\vartheta \mapsto \mathrm{cst}(\vartheta)$ on the m-fold twists of D *costs* n *squares*, for a natural number n, if for every family θ that is fit for D the family $(\ell, \iota) \mapsto |\mathrm{cst}(\theta_{\ell,\iota})/\mathrm{cst}(1)|^{-2}$ has height at most $n \cdot 2\,t(D)\,x^{999}$. There is a function $\mathrm{cst}_D^{\mathrm{vol}}$ that costs m^2 squares such that for every m-fold twist ϑ,

$$\mathfrak{z}_D(\vartheta) \neq 0 \qquad \text{and} \qquad \mathfrak{z}_D(\vartheta) = \left|\mathrm{cst}_D^{\mathrm{vol}}(\vartheta)\right|^{\dim \mathrm{Row}(D)} \cdot \prod_{i=1}^{m} \mathrm{vol}_D(\vartheta, i),$$

where $\mathrm{vol}_D(\vartheta, i)$ is the volume of the i-th lift of the chain at the twist ϑ^i (unit 143).

Input 21 (the height of one lift; unit 143)**.** In Settings 8.1, 10.1 and 11.1, let θ be a family of m-fold twists that is fit for D, and let i be a natural number with $1 \le i \le m$. Then the family $(\ell, \iota) \mapsto \operatorname{vol}_D(1,i)/\operatorname{vol}_D(\theta_{\ell,\iota}, i)$ has height at most

$$\dim \operatorname{Row}(D) \cdot k(D) \cdot \Big(\log b \cdot \frac{\operatorname{budget}(D)}{m\, k(D)} - \mathsf{U}(D) \Big).$$

Each lift repays one direction: this is where $\mathsf{U}(D)$, and so the main amount, enters the lower bound. Chapter VII.

Input 22 (crude rows; unit 147)**.** In Settings 8.1, 10.1 and 11.1 there is a function $\operatorname{cst}^{\mathrm{cr}}_D$ on the m-fold twists of D, with non-zero complex values, that costs $2m^2$ squares, such that $\mathrm{PF}(D)$ is spanned over $\mathbb{C}$ by the forms F with these two properties: for every m-fold twist ϑ, every prime number ℓ that is prime to ϑ and every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_\ell$, the form $(\operatorname{cst}^{\mathrm{cr}}_D(\vartheta)/\operatorname{cst}^{\mathrm{cr}}_D(1)) \cdot \Theta^{\flat}_{D,\vartheta}(F)$ is j-integral; and $\Theta^{\flat}_{D,1}(F)$ is pointwise at most $\exp(x_1^2 b^2)$ at every $\sigma \in \operatorname{Aut}(\mathbb{C})$. We call such forms *crude*.

Input 23 (one determinant; unit 135)**.** In Settings 8.1, 10.1 and 11.1, let $\theta = (\theta_{\ell,\iota})$ be a family of m-fold twists of D and let $y_1, \dots, y_{n'}$ be a basis of $\operatorname{Row}(D)$. Let B, δ, h be real numbers, n'' a natural number, $(\eta_\ell)_{\ell \in \mathbb{N}}$ real numbers and $(H_{\ell,\iota})$ a family of non-zero complex numbers. Assume:

(1) $\Theta_{D,1}$ is injective, and $|\sigma(\det(\langle \Theta_{D,1} y_i, \Theta_{D,1} y_{i'} \rangle)_{i,i'})| \le \mathrm{e}^{B}$ for every $\sigma \in \operatorname{Aut}(\mathbb{C})$;

(2) the family $(\ell, \iota) \mapsto |H_{\ell,\iota}|^{-2}$ has height at most h;

(3) $\sum_{\ell \in J} \eta_\ell \le \delta$ for every finite set $J \subset \mathbb{N}$;

(4) for every pair (ℓ, ι) and every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_\ell$: if $F, F' \in \mathcal{A}_{D,\theta_{\ell,\iota}}$, F' is j-integral and F is integral for the composite of j with complex conjugation, then $|j(\langle F, F' \rangle)|_\ell \le 1$;

(5) for every pair (ℓ, ι) and every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_\ell$ there is a complex $n' \times n'$ matrix u with $\mathrm{e}^{-\eta_\ell} |j(H_{\ell,\iota})|_\ell^{n''} \le |j(\det u)|_\ell$ such that all $\Theta_{D,\theta_{\ell,\iota}}(\sum_{i'} u_{ii'} y_{i'})$ are j-integral.

Then the family $(\ell, \iota) \mapsto \mathfrak{z}_D(\theta_{\ell,\iota})/\mathfrak{z}_D(1)$ has height at most $B + 2\delta + n'' h$.

A special case: the lemma of unit 135 is stated for an arbitrary family of linear maps from one space into inner product spaces. Chapter IV.

Input 24 (integral forms pair integrally; units 102, 152, 147)**.** In Settings 8.1 and 10.1, hypothesis (4) of Input 23 holds for every twist: for a twist ϑ, a prime number ℓ, a ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_\ell$ and $F, F' \in \mathcal{A}_{D,\vartheta}$ with F' j-integral and F integral for the composite of j with complex conjugation, $|j(\langle F, F' \rangle)|_\ell \le 1$.

Unit 102 proves this with a factor: a common multiple of the orders of the stabilisers that occur in the Petersson product. Units 152 and 147 show that at the level of $\mathcal{A}_{D,\vartheta}$ all these stabilisers are trivial.

Input 25 (Hadamard and Fischer; unit 102)**.** In Settings 8.1 and 10.1, let ϑ be a twist, $\sigma \in \mathrm{Aut}(\mathbb{C})$, B and V real numbers, and $F_1, \dots, F_n, F_1', \dots, F_{n''}' \in \mathcal{A}_{D,\vartheta}$.
(a) If $\|F_i'\|_\sigma^2 \le \mathrm{e}^B$ for all i, then $\mathrm{covol}_\sigma^2(F_1', \dots, F_{n''}') \le \mathrm{e}^{n''B}$.
(b) If moreover $\mathrm{covol}_\sigma^2(F_1, \dots, F_n) \le \mathrm{e}^V$, then $\mathrm{covol}_\sigma^2(F_1, \dots, F_n, F_1', \dots, F_{n''}') \le \mathrm{e}^{V+n''B}$.
(c) If $\mathrm{covol}_{\sigma'}^2(F_1, \dots, F_n) \le \mathrm{e}^V$ for every $\sigma' \in \mathrm{Aut}(\mathbb{C})$, then $|\sigma(\det(\langle F_i, F_{i'}\rangle)_{i,i'})| \le \mathrm{e}^V$.

Lemma 11.2 (the height of the inverse ratio of volumes)**.** *Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1, 10.1 and 11.1), and let $\theta = (\theta_{\ell,\iota})$ be a family of m-fold twists of D that is fit for D. Then the family $(\ell, \iota) \mapsto \mathfrak{z}_D(1)^2/\mathfrak{z}_D(\theta_{\ell,\iota})^2$ has height at most*

$$2 \dim \mathrm{Row}(D) \cdot (2 \log b \cdot \mathrm{budget}(D) - h_{\mathrm{main}}(D)).$$

Proof. By Input 20, for every pair (ℓ, ι),

$$\frac{\mathfrak{z}_D(1)^2}{\mathfrak{z}_D(\theta_{\ell,\iota})^2} = \Big(\prod_{i=1}^{m} \frac{\mathrm{vol}_D(1,i)}{\mathrm{vol}_D(\theta_{\ell,\iota}, i)}\Big)^2 \cdot \Big(\Big|\frac{\mathrm{cst}_D^{\mathrm{vol}}(\theta_{\ell,\iota})}{\mathrm{cst}_D^{\mathrm{vol}}(1)}\Big|^{-2}\Big)^{\dim \mathrm{Row}(D)}.$$

By Inputs 21 and 18(a) the product over i has height at most m times the bound of Input 21, which is $\dim \mathrm{Row}(D) \cdot (\log b \cdot \mathrm{budget}(D) - h_{\mathrm{main}}(D))$ by Definition 9.1; here $m\,k(D) \neq 0$ by (S0). The function $\mathrm{cst}_D^{\mathrm{vol}}$ costs m^2 squares, so the last family in brackets has height at most $m^2 \cdot 2\,t(D)\,x^{999} \le 2 \log b \cdot \mathrm{budget}(D)$, by (S5) and Input 18(b). By Input 18(a) the height of the product is at most $2 \dim \mathrm{Row}(D)\,(\log b \cdot \mathrm{budget}(D) - h_{\mathrm{main}}(D)) + \dim \mathrm{Row}(D) \cdot 2 \log b \cdot \mathrm{budget}(D)$. □

LEAN `Data.heightLe_volume_ratio_sq`

Setting 11.3 (an almost spanning family of small index and small covolume)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1). Let n be a natural number, $y = (y_1, \dots, y_n)$ a family of rows in $\mathrm{Row}(D)$, and δ and V real numbers, such that:

(i) the family y is linearly independent over $\mathbb{C}$;
(ii) $(1 - 4/b^2) \cdot \dim \mathrm{Row}(D) \le n$;
(iii) y has D-index at most δ;
(iv) $\mathrm{covol}_\sigma^2(\Theta_{D,1} y_1, \dots, \Theta_{D,1} y_n) \le \mathrm{e}^V$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$.

Lemma 11.4 (the height of the ratio of volumes)**.** *In Setting 11.3, let $\theta = (\theta_{\ell,\iota})$ be a family of m-fold twists of D that is fit for D (Setting 11.1). Then the family $(\ell, \iota) \mapsto \mathfrak{z}_D(\theta_{\ell,\iota})/\mathfrak{z}_D(1)$ has height at most $V + 2\delta + \dim \mathrm{Row}(D) \cdot b$.*

Proof. Completion to a basis. Let $\mathrm{cst}_D^{\mathrm{cr}}$ be as in Input 22. The map $\varpi_D(1)$, for the unit element of $\mathsf{G}(D)$, maps $\mathrm{PF}(D)$ onto $\mathrm{Row}(D)$, so the rows $\varpi_D(1)F$ with F crude span $\mathrm{Row}(D)$. Since y is linearly independent (i), there are $n'' = \dim \mathrm{Row}(D) - n$ crude forms $F_1, \dots, F_{n''}$ such that $y_1, \dots, y_n, \varpi_D(1)F_1, \dots, \varpi_D(1)F_{n''}$ is a basis of $\mathrm{Row}(D)$. We apply Input 23 to this basis, to the family θ, and to $H_{\ell,\iota} = \mathrm{cst}_D^{\mathrm{cr}}(\theta_{\ell,\iota})/\mathrm{cst}_D^{\mathrm{cr}}(1)$.

Hypothesis (1). $\Theta_{D,1}$ is injective because $\mathfrak{z}_D(1) \neq 0$ (Input 20). Each F_i is crude, so $\|\Theta_{D,1}(\varpi_D(1)F_i)\|_\sigma^2 \le \exp(x^{99} + x_1^2 b^2)$ for every σ, by Input 13(a). With (iv) and

Input 25(b), (c), the conjugates of the Gram determinant of the images of the basis under $\Theta_{D,1}$ have absolute value at most e^{B} with $B = V + n''\,(x^{99} + x_1^2 b^2)$.

Hypotheses (2), (3), (4). The function $\mathrm{cst}_D^{\mathrm{cr}}$ costs $2m^2$ squares and θ is fit, so (2) holds with $h = 2m^2 \cdot 2\,t(D)\,x^{999}$. Let (η_ℓ) be as in Definition 10.5 for the family y, by (iii); this is (3). And (4) is Input 24.

Hypothesis (5). Let (ℓ, ι) be a pair and $j\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism. The prime ℓ is prime to $\theta_{\ell,\iota}$, because θ is fit. By (iii) there is an $n \times n$ matrix u_0 over O_j with $|j(\det u_0)|_\ell \geq \mathrm{e}^{-\eta_\ell}$ such that all $\Theta_{D,\theta_{\ell,\iota}}(\sum_{i'}(u_0)_{ii'}y_{i'})$ are j-integral. Let u be the block matrix with the blocks u_0 and $H_{\ell,\iota}$ times the identity matrix of size n''. Then $|j(\det u)|_\ell \geq \mathrm{e}^{-\eta_\ell}|j(H_{\ell,\iota})|_\ell^{n''}$. The new rows of the second block are the $H_{\ell,\iota}\,\varpi_D(1)F_i$, and $\Theta_{D,\theta_{\ell,\iota}}(H_{\ell,\iota}\,\varpi_D(1)F_i) = H_{\ell,\iota}\Theta^{\flat}_{D,\theta_{\ell,\iota}}(\varpi_D(1)F_i)$ is j-integral, by the first property of crude forms and Input 13(b).

Conclusion. Input 23 gives the height bound $V + 2\delta + n''\,(x^{99} + x_1^2 b^2 + 4m^2 t(D) x^{999})$. By (ii), $n'' \leq 4b^{-2}\dim \mathrm{Row}(D)$, and by (S4) the bracket is at most $\frac{1}{4}b^3$. So the bound is at most $V + 2\delta + \dim \mathrm{Row}(D) \cdot b$, and Input 18(b) concludes. □

LEAN `Data.heightLe_volume_rows`

Theorem C (integral forms are long)**.** Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1). Let n be a natural number, $y = (y_1, \dots, y_n)$ a family of rows in $\mathrm{Row}(D)$, and δ and V real numbers. Assume that the family y is linearly independent over $\mathbb{C}$, that $(1 - 4/b^2) \cdot \dim \mathrm{Row}(D) \leq n$, that y has D-index at most δ, and that $\mathrm{covol}_\sigma^2(\Theta_{D,1}y_1, \dots, \Theta_{D,1}y_n) \leq \mathrm{e}^V$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$. Then

$$\dim \mathrm{Row}(D) \cdot (h_{\mathrm{main}}(D) - 3\log b \cdot \mathrm{budget}(D)) \leq V + 2\delta.$$

Proof. The hypotheses are those of Setting 11.3. Let θ be a family of m-fold twists that is fit for D (Input 19). For every pair (ℓ, ι) the numbers $\mathfrak{z}_D(1)$ and $\mathfrak{z}_D(\theta_{\ell,\iota})$ are not zero (Input 20), so

$$\Big(\frac{\mathfrak{z}_D(\theta_{\ell,\iota})}{\mathfrak{z}_D(1)}\Big)^2 \cdot \frac{\mathfrak{z}_D(1)^2}{\mathfrak{z}_D(\theta_{\ell,\iota})^2} = 1.$$

By Lemma 11.4 and Input 18(a) the first factor has height at most $2\,(V + 2\delta + \dim \mathrm{Row}(D) \cdot b)$; by Lemma 11.2 the second has height at most $2\dim \mathrm{Row}(D)\,(2\log b \cdot \mathrm{budget}(D) - h_{\mathrm{main}}(D))$. So the constant family 1 has height at most the sum, and by the product formula, Input 18(c),

$$0 \leq 2\,(V + 2\delta + \dim \mathrm{Row}(D) \cdot b) + 2\dim \mathrm{Row}(D) \cdot (2\log b \cdot \mathrm{budget}(D) - h_{\mathrm{main}}(D)).$$

With $b \leq \log b \cdot \mathrm{budget}(D)$, which is (S6), this is the claim. □

LEAN `Data.integral_forms_long`

Corollary 11.5 (Theorems A and B together)**.** *Let P be parameters and D admissible data for P, with components x, x_1, b, m, r (Settings 8.1 and 10.1). There are a natural number n and a family $y = (y_1, \dots, y_n)$ of rows in $\mathrm{Row}(D)$ such that: the family y is linearly independent over $\mathbb{C}$; $(1 - 4/b^2) \cdot \dim \mathrm{Row}(D) \leq n$; there is a*

real number $\delta \le 5 \dim \mathrm{Row}(D) \cdot \log(1+b^2) \cdot \mathrm{budget}(D)$ *such that* y *has* D*-index at most* δ*; and for every* $\sigma \in \mathrm{Aut}(\mathbb{C})$*,*

$$\mathrm{covol}_\sigma^2(\Theta_{D,1} y_1, \dots, \Theta_{D,1} y_n) \le \exp\Big(n \cdot \big(h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \log b \cdot \mathrm{budget}(D)\big)\Big).$$

Proof. Let q and S be as in Theorem A, and $\mathcal{T}$ as in Theorem B. Since S spans $\mathrm{Col}^{\mathrm{ram}}(D)$ and $q \neq 0$, the rows $q\mathcal{P}_D(\gamma)\psi$ with $\gamma \in \mathcal{T}$, $\psi \in S$ span the space $\sum_{\gamma \in \mathcal{T}} \mathcal{P}_D(\gamma)(\mathrm{Col}^{\mathrm{ram}}(D))$. Choose a basis $y_1, \dots, y_n$ of this space among them. Then y is linearly independent and $n \ge (1 - 4/b^2) \dim \mathrm{Row}(D)$ by Theorem B. By Theorem A(b), with $S \subseteq \mathrm{Col}^{\mathrm{ram}}_{\mathrm{int}}(D)$, the family y has D-index at most $\delta = \#\mathcal{T} \cdot \dim \mathrm{Col}(D) \cdot \mathrm{budget}(D)$, and $\delta \le 5 \dim \mathrm{Row}(D) \cdot \log(1+b^2) \cdot \mathrm{budget}(D)$ by Theorem B and $\mathrm{budget}(D) > 0$. Finally each $\|\Theta_{D,1} y_i\|_\sigma^2$ is at most $\exp(h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \log b \cdot \mathrm{budget}(D))$ by Theorem A(a), and Hadamard's inequality, Input 25(a), bounds the covolume. □

LEAN `Data.exists_family_covolumeSq_le`

12 Where the results are used

All consumers are in the last unit of the proof (unit 154, Chapter I), which has three steps.

The main inequality $m \cdot \mathrm{rem}(D) \le (\log b)^2 \cdot \mathrm{budget}(D)$. Take the family of Corollary 11.5 and apply Theorem C to it, with $V = n\,(h_{\mathrm{main}}(D) - m \cdot \mathrm{rem}(D) + \log b \cdot \mathrm{budget}(D))$. The main amount occurs on both sides, once with the factor $\dim \mathrm{Row}(D)$ and once with the factor n; Lemma 9.5 pays for the difference, since $\dim \mathrm{Row}(D) - n \le 4b^{-2} \dim \mathrm{Row}(D)$. After division by $\dim \mathrm{Row}(D)$ the main amount has cancelled, and what remains is the inequality.

The one-sided bound $R_{d,N_0}(x) \le x^{8\varepsilon - 1/2}$ for large x. Theorem 4 solves for $R_{d,N_0}(x)$, and leaves the combination $R_{d,N_0}(x_1) - X\,R_{d,1}(x_1)$ with $X = \#\mathrm{tops}(D)/\#\mathrm{thick}(D)$ to be bounded from above. Theorem 1, for the moduli N_0 and 1, and Theorem 3 provide a point v_1 in the window $[v_0, v_0^2]$, $v_0 = 10^6 \log x$, at which this combination is at most e^{-v_0}, and the second scale is moved to $x_1 = \mathrm{e}^{v_1}$; the main inequality bounds the rest.

The zero-free half-plane. Theorem 2 with $M = N_0$ and $c = N_0/2 - 1$.

Inside the unit, Lemmas 4.1 to 4.4 serve Theorems 1 and 4 and Lemma 9.5; Proposition 7.1 serves Theorem 3; Proposition 9.4 and Lemma 10.6 serve Theorem A; Lemmas 11.2 and 11.4 serve Theorem C.

13 Notes on the formal text

Conventions of Lean that the statements hide. Division by zero gives zero. So the residue function of Theorem 1 is defined at $s = 0$ and $s = 1$, with the value 0, as stated; at $s = 1$ the numerator vanishes anyway, by Input 1. The logarithmic derivative of a function is 0 at its zeros, so $G_{d,M}(s)$ is defined for every s; the proofs use it only as a meromorphic function and at points where no $\tilde{L}(\,\cdot\,, \xi)$, $\tilde{L}(\,\cdot\,, \xi\chi_d)$ vanishes. The remainder $R_{d,M}(x)$ is defined for every real x, with Lean's logarithm of a number ≤ 0; only $x > 0$ is used. The integral of a function that is not integrable

is 0, which is why Proposition 7.1 and Input 6 assert integrability separately. The weight $\lambda_{d,M}(\nu)$ and the sums $A_{d,M}(i,x)$ are defined for every natural number M, also $M=0$, where $\mathbb{Z}/0=\mathbb{Z}$ and the weight vanishes identically.

Definition 2.8. The formal definition asks that Φ be meromorphic at every point of $\mathbb{C}$ as a function on $\mathbb{C}$; its values at its poles are arbitrary. Condition (P3) is stated for the product $(s-1)\Phi(s)$ as a function, so its value at $s=1$ is 0; the clause on that value in (P3) and Remark 2.9 are our reading of it, and the comment above the formal definition says the same: no pole at 1 is allowed.

Theorem 1. The hypothesis $d\equiv 7 \pmod 8$ is used only through $d\neq 2$ (Step 3). The formal proof orders the steps differently: it proves the Laplace identity (our Steps 3 to 5) after it has used it, as a pending goal, to show that the constant is real (Step 6); the order of the goals was inferred by the reader of the dossier from the structure of the term, and the writer agrees with that reading. The formal statement speaks of the function $v\mapsto R_{d,M}(\mathrm{e}^{v})$ and of a residue function given by a formula; the names $\Phi_{d,M}$ and $\mathrm{res}_{d,M}$ are ours, after the overview of the write-up, and the transform (5.1) and the constant $|\kappa_{d,M}|+5$ are the witnesses of the formal proof.

Theorem 2. The conclusion is about $\tilde{L}(\rho,\chi)$; for principal χ this is $(\rho-1)L(\rho,\chi)$. The hypothesis on the primes $d\equiv c$ is one conjunction in the formal text, and it is used three times: for Input 5, for Theorem 1, and for the one-sided bound. In the formal statement d runs over the type of prime numbers and $d\equiv c \pmod M$ is written as an equality in $\mathbb{Z}/M$.

Proposition 7.1: the boundary of the statement. The formal statement contains a local definition of the function $v\mapsto v^{i}\mathrm{e}^{-3v}\mathcal{E}(v)$, written with a sign of definition. The census of the workspace, which reads the text line by line, takes that sign for the end of the statement; the dossier corrects this, and the writer read the complete statement in the source: it ends after the bound $i!\,v_0/\mathfrak{r}^{i}$. The quantifiers of the formal statement are filters, *for all* $\mathfrak{r}>3$ *close to* 3 and *for all large* v_0; the proposition writes them out, in this order. Its proof uses neither the meromorphy of Φ nor (P4); the residues of a polar function enter the proof only through Landau's lemma.

Arguments that the census lists and Lean does not take. The census reads the arguments of a declaration from its text and counts every variable of the surrounding section whose name occurs in the statement. In three places a bound variable of the statement has the name of such a section variable, and Lean, which the writer follows, does not take it as an argument. *(1)* Corollary 11.5: its statement binds its own n, y and δ under existential quantifiers, and its only arguments are the parameters and the data. The reader of the dossier could not confirm this with Lean; the writer confirms it from the use of the corollary in the proof of the main inequality, where it is applied to the data alone and nothing could determine further arguments. *(2)* Input 5: the character ξ is bound by a universal quantifier inside the statement and is not an argument. *(3)* Definition 10.3: the formal declaration takes the data and γ, and its value is a linear map; the census reads the arrow in the type of that map as

one more argument. The notation of this note has a third place for that reason, and it is left empty when the map itself is meant.

Theorem A. The formal statement names the family of maps $\gamma \mapsto q\,\mathcal{P}_D(\gamma)$: it says that there are q and a family equal to this one, with the two properties. We have substituted the family. In (b) the finite sets J of Definition 10.5 are arbitrary finite sets of natural numbers, not only sets of primes, as in the formal text. The formal proof of (b) obtains the bound for the determinant from divisibility in the valuation ring O_j, as we do.

Theorem B. Its first two assertions, that there are columns and rows, are part of the formal statement. The filling theorem is stated for columns and the operator ram_D, and Theorem B for ramified columns; the proof passes from one to the other.

Theorem C. In the formal text the four hypotheses of Setting 11.3 are variables of the section, shared by Lemma 11.4 and Theorem C, in the order (i), (ii), (iii), (iv); Lemma 11.2 takes none of them. The formal proof of Lemma 11.4 gets the injectivity of $\Theta_{D,1}$ from a lemma that is applied automatically and that we have not located; we derive it from $\mathfrak{z}_D(1) \neq 0$, which is the same fact.

Two names for the chain. The formal text has two maps for the chain of lifts on $\mathrm{PF}(D)$: one with values in forms that are functions with vector values, for which pointwise sizes and integrality of values are defined, and one with values in the space that carries the Petersson product. They have the same values, and the proofs of Theorems A and C pass from one to the other without comment; we write $\Theta^{\flat}_{D,\vartheta}$ for both.

What the reader of the dossier was unsure of. Besides the three points above (the boundary of the statement of Proposition 7.1, the arguments of Corollary 11.5 and of Definition 10.3): the facts of Mathlib that Lemma 4.4 needs, namely that $(s-1)\zeta(s)$ has the value 1 and the derivative C_{Eu} at $s = 1$, were inferred by the first reader from the proof going through, because the pinned version of Mathlib was not at hand. The second reader of this write-up has since found both at the pin, and also the value $\prod_{p\mid M}(1-1/p)$ of Definition 2.2 and the two statements of Mathlib that Step 3 and Step 4 of the proof of Theorem 1 quote (orthogonality of characters against von Mangoldt's function, and partial summation). For this note the writer did not open Mathlib: every fact of Mathlib that the note uses rests on the second reader's check at the pin. This is said of this note only; the three notes of Chapter I list in their appendices the declarations of Mathlib that their writer read at the pinned commit. The readings of the Inputs 8 to 25 come from their formal statements and comments, not from their proofs; the chapters on the units that own them are the reference.

The dossier, and its second reading. The second reader of this write-up compared the dossier with the source and asked for six corrections; this note agrees with all of them. Two concern words of the dossier that were wrong as mathematics while its quotations were exact. In the structured proof of Theorem 4, one step says that $(-\nu)\cdot\tau$ runs over the places of class $-\nu$ as τ runs over the tops; this holds for ν

prime to $N_1(D)$ only, and for the other ν the formal text makes $(-\nu)\cdot\tau=\tau$ (Step 1 above treats both cases). In the structured proof of Lemma 9.5, an intermediate bound had absolute values around $z/\nu-w$ where the positive part stands; with the positive part the bound $|z|/\nu$ is correct. The other four are points of exposition: the quadratic character is that of K only for $d\equiv 3 \pmod 4$ (Definition 2.1); the value of the entire L-function of a principal character at $s=1$ (Definition 2.2); the vanishing at $s=1$ that makes the singularity removable (Remark 2.9, Input 7); and the difference between the rank $k(D)$ and the dimension of $\mathrm{Col}(D)$ (Setting 10.1).

What of the unit the final theorems use. The last unit of the proof uses Theorems 1, 2, 3, 4 and C, Corollary 11.5 and Lemma 9.5 directly; every other declaration of the unit is used by one of these.

How this note was written. From the dossier of unit 151: its statements, its 18 structured proofs with 104 leaf steps, which a program compared with the source, and its readings of the declarations of other units. The writer read in the Lean text itself: the four files of the unit completely, statements and proofs; the file of the background library with the definition of polar functions, Landau's lemma and the elementary inputs, completely; the definitions of the characters, of the entire L-function and of the Chowla–Selberg constant; the statement and the last step of the proof of Input 5; the record of the data and the definitions attached to it that Setting 8.1 uses; the statements, as quoted in the dossier, of every Input of Part II, and in the source the definitions of the height, of fit families, of twists, of the index relation of unit 149 and of the mechanism that compares sizes; and the last unit of the proof, to see how the results are used. Every statement of the note was compared with its formal statement, argument by argument and in the order of the quantifiers. The relation of Inputs 1, 4 and 5 to the literature is the second reader's comparison, as their boxes say. Not opened for this note: the proofs of the Inputs of Part II, and Mathlib, whose facts were checked at the pin by the second reader, as said above.

The arguments are those of the formal proofs, with these differences. In Theorem 3 the final numerical comparison is done by hand here and by an arithmetic tactic there. In Theorem 4 the counting of Step 1 is written out here; the formal proof reindexes the sum by a translation of the group of places and uses a lemma of unit 152, which says that the place named by an integer ν has class -1 modulo N_0 exactly when $\nu\equiv -1$, also for the integers that are not prime to $N_1(D)$. Remarks 2.10, 3.1, 6.1 and 7.2, and the estimate of orders of magnitude after Lemma 9.5, are ours and have no formal counterpart.

Legend. The note changes some letters of the formal text, never the number of arguments. The modulus is M here, and M or N there. The unit class c of Theorem 2 and Input 5 is `a`; the height z of Input 5 is `y`. The exponent i of the weighted sums is `r`, and their real argument x is `y`; the natural number a and the point x of Lemma 4.3 are `A` and `z`. A polar function $\mathcal{E}$ with residue function ω is `E` with `r`; in Theorem 3, $\mathcal{E}_1, \omega_1, \mathcal{E}_2, \omega_2$ are `E`, `r`, `E'`, `r'`, the parameter v_0 is `t`, and the point v_1 is `u`. In Proposition 7.1 the radius $\mathfrak{r}$ is `R`, the number v_0 is `t` and the order i is `k`. In Input 7, s_0, s_1, s_2 and Φ are `z`, `a`, `σ` and `Ψ`, and the radius $\mathfrak{r}_0$ is `ε`. In Lemma 10.6 the set J is `T`, the exponents e_ℓ are `g l`, and primes are `l` throughout. In Part II the scales x, x_1, b are the exponentials of the components `logX`, $\texttt{logX}_1$, `logB` of the data; a place τ is `σ` or `τ`; an element γ of $\mathsf{G}(D)$ is `s`; a finite subset $\mathcal{T}$ is `t`; a ramified column ψ is `φ`; a ring homomorphism j is `ι`, of the class `PadicPlace`; the numbers η_ℓ are `e l`, and a finite set J of natural numbers is `U`. The objects of other units have these formal names: $\mathrm{tops}(D)$, $\mathrm{thick}(D)$, $\mathrm{budget}(D)$, $\mathsf{U}(D)$, $h_0(D)$ are `Data.tops`,

`Data.thick`, `Data.budget`, `Data.dirCost`, `Data.heightPerRow`; $w_D(\tau)$, $\mathrm{Ask}_D(z,\tau)$ and $\mathrm{jet}_D(i)$ are `Data.nominalWeight`, `Data.primeSum` and `Data.jetSize`; $\mathrm{Col}(D)$, $\mathrm{Col}^{\mathrm{ram}}(D)$, $\mathrm{Row}(D)$, $\mathsf{G}(D)$ are `Data.Column`, `Data.ramifiedColumns`, `Data.rows`, `Data.G`; Poin_D and $\varpi_D(\gamma)$ are `Data.poincare` and `Data.goodProjTranslate`; $\Theta_{D,\vartheta}$ and $\mathfrak{z}_D(\vartheta)$ are `Data.θ` and `Data.𝔷`; the height is `HeightLe`, and fitness is `Data.IsFitFamily`.

Six statements, as the artifact has them. The remainder; Theorem 1; Theorem 2; polar functions; Landau's lemma; Theorem 4.

Notation

$\mathbb{N}, \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \mathbb{C}$ natural numbers with 0, integers, rational, real, complex numbers

$\mathbb{C}_\ell, \overline{\mathbb{Q}}_\ell$ the completion of an algebraic closure of the ℓ-adic numbers; an algebraic closure; $|\cdot|_\ell$ their absolute value

Re, Im real and imaginary part

e, $\log$, $(z)_+$ base of the natural logarithm; natural logarithm; $\max(z, 0)$

$O(\cdot)$, $o(1)$ Landau's symbols

d a prime number; in Part II the second parameter

M a natural number, the modulus of the characters

ν a natural number, the variable of the prime sums

p, e a prime; an integer exponent; e_ℓ the exponents of Lemma 10.6

Λ, φ von Mangoldt's function; Euler's function

χ_d, χ_K the quadratic character modulo d (Definition 2.1); it is the character of $K = \mathbb{Q}(\sqrt{-d})$ if $d \equiv 3 \pmod 4$

ξ, χ, $\mathbf{1}$ Dirichlet characters modulo M; the character modulo 1

$\xi\chi_d$ the twist of ξ, a character modulo Md (Definition 2.1)

$[\chi \text{ principal}]$ the number 1 if χ is principal, 0 otherwise

$L(s,\chi)$, $\tilde{L}(s,\chi)$, $\tilde{L}(\cdot,\chi)$ the Dirichlet L-function; the entire L-function, its values and the function (Definition 2.2); $\tilde{L}'$ its derivative

ζ the Riemann zeta function

$\mathrm{ord}_s f$ order of vanishing at s of an entire function $f \neq 0$

C_{Eu}, $\mathrm{cs}(d)$ Euler's constant; the Chowla–Selberg constant (Definition 2.3)

$\lambda_{d,M}(\nu)$ the weight (Definition 2.4)

$A_{d,M}(i,x)$ the weighted sums (Definition 2.5)

$G_{d,M}(s)$, $\kappa_{d,M}$ the mean of the logarithmic derivatives and its real part at $s = 1$ (Definition 2.6)

$R_{d,M}(x)$ the remainder (Definition 2.7)

$\Phi_{d,M}(s)$, $\mathrm{res}_{d,M}(s)$ the transform of the remainder, (5.1); its residue function (Theorem 1)

s, s', s_0, s_1, s_2 complex numbers, the variable of the transforms

ρ a complex number with $\mathrm{Re}\,\rho > 0$; in Theorem 2 the point where a zero is excluded

β a real number, the exponent of the one-sided bound

c a unit of $\mathbb{Z}/M$, the class of the primes d

x, z, v real numbers: x the argument of the remainder and of the weighted sums, v its

logarithm; x_0 (an abscissa of convergence), x_*, v_* particular values

i a natural number: an exponent, the order of a moment or of a derivative; in Part II also the index of a row or of a lift, with i', i_0

a a natural number (Lemma 4.3); in the proofs of §9 it abbreviates $a(D)$

$\mathcal{E}, \mathcal{E}_0, \mathcal{E}_1, \mathcal{E}_2$; $\omega, \omega_1, \omega_2$ functions $\mathbb{R} \to \mathbb{R}$; functions $\mathbb{C} \to \mathbb{C}$, residue functions

$\mathrm{Polar}(\mathcal{E}, \omega)$ $\mathcal{E}$ is polar with residue function ω (Definition 2.8)

C, C_1, $C_\mathfrak{r}$; Φ real constants; a meromorphic function on $\mathbb{C}$, the transform; $\Phi^{(i)}$ its i-th derivative

v_0, v_1, X the parameter of a window, a point of it, a real factor (Theorem 3)

$\mathfrak{r}$, $\mathfrak{r}_0$, Δ radii of discs: $\mathfrak{r}_0$ the radius in Input 7 and the bound of Proposition 7.1, $3 < \mathfrak{r} < \mathfrak{r}_0$; a positive real number, in the box of Input 5 and in the proof of that proposition

ε a real number with $0 < \varepsilon < \frac{1}{100}$, in the exponent of the one-sided bound of Chapter I

$I(v)$ the auxiliary function in the proof of Theorem 3

$P = (N_0, d)$, D parameters and admissible data (Setting 8.1)

x, x_1, b; m, r the scales of D; its two natural numbers

K, $E(D)$, $N_1(D)$, $f(D)$ $\mathbb{Q}(\sqrt{-d})$; the field of the data, the order of its roots of unity, the number of its infinite places

τ, $\nu \cdot \tau$ an infinite place of $E(D)$; its translate by the integer ν

$\mathrm{tops}(D)$, $\mathrm{thick}(D)$ the places of class 1 modulo N_0; the thick places

$k(D)$, $t(D)$, $a(D)$ $r + 1 - m$; $5r$; the least multiple of $N_1(D)$ that is $\geq xb$

$\mathrm{budget}(D)$ $f(D)\, a(D)\, (\log b)^3$

$w_D(\tau)$, $\bar{w}_D$, w the nominal weight, the mean of its logarithm; a real weight

$\mathrm{Ask}_D(z, \tau)$, $\mathrm{Ask}^{\mathrm{main}}(D)$ the prime sum of order z at τ; its expected value (Definition 9.2)

$g(D)$, $\mathrm{rd}_{E(D)}$, per_D, Ω, π product of two primes of the data; root discriminant; the period term $\log(g(D)\, \mathrm{rd}_{E(D)}/2\pi)$; the period; the number $3.14\ldots$

$\mathrm{jet}_D(i)$, $\mathsf{U}(D)$, $N(D)$, $h_0(D)$ jet size, cost of one direction, level, height per row (Setting 8.1)

$h_{\mathrm{main}}(D)$, $\mathrm{rem}(D)$ the main amount and the remainder of the data (Definitions 9.1, 9.3)

$\mathrm{Col}(D)$, $\mathrm{Col}^{\mathrm{ram}}(D)$, $\mathrm{Col}^{\mathrm{ram}}_{\mathrm{int}}(D)$ columns, ramified columns, integral ramified columns

ψ, ψ_i, ψ'_i, ψ_0 columns

$\mathsf{G}(D)$, γ, $\mathcal{T}$ the finite group of the data, an element, a finite subset

$\mathrm{PF}(D)$, $\mathrm{Row}(D)$, $y = (y_i)$, n forms of principal level, rows, a family of n rows; n', n'' further numbers of rows

$\varpi_D(\gamma)$, Poin_D, ram_D translation followed by the projection to rows; Poincaré series; the ramifying operator

$\mathrm{inc}(D)$, $\mathcal{P}_D(\gamma)\psi$ the scaled inclusion and the Poincaré maps (Definitions 10.2, 10.3)

ϑ, $Q(\vartheta)$, $\theta = (\theta_{\ell,\iota})$ a twist, its set of ramified primes; a family of m-fold twists

$\Theta^\flat_{D,\vartheta}$, $\Theta_{D,\vartheta}$, $\mathcal{A}_{D,\vartheta}$ the chain of lifts on $\mathrm{PF}(D)$ and on the rows; its target

$\mathfrak{z}_D(\vartheta)$, $\mathrm{vol}_D(\vartheta, i)$ the volume of the chain; of its i-th lift

F, F', F_i forms, in $\mathcal{A}_{D,\vartheta}$ or in $\mathrm{PF}(D)$

σ, $\mathrm{Aut}(\mathbb{C})$ an automorphism of the field $\mathbb{C}$; their group

$\|F\|^2_\sigma$, $\mathrm{covol}^2_\sigma(F_1, \ldots, F_n)$ Petersson norm and squared covolume of σ-conjugates

ℓ, j, O_j a prime number (in Lemma 10.6 and in sums, a natural number); a ring homomorphism $\mathbb{C} \to \mathbb{C}_\ell$; its valuation ring in $\mathbb{C}$

ι a field isomorphism $\mathbb{C} \to \overline{\mathbb{Q}}_\ell$

η_ℓ, J real numbers indexed by $\ell \in \mathbb{N}$; a finite set of natural numbers

u, u_0 square matrices

$\mathrm{ind}_D(y) \leq \delta$, δ y has D-index at most δ (Definition 10.5); a real number

V, B, h, h' real numbers: bounds for logarithms of covolumes, of sizes, of heights

q, S the rational number and the spanning set of Theorem A

Ψ, $\mathrm{Ch}_D(\vartheta, \Psi)$ a good datum; the chain of lifts between definite spaces

$\mathrm{gain}_D(\ell)$, $\mathrm{err}_D(\ell)$, $\mathrm{nonsplit}(D)$ gain and allowed loss at ℓ; the primes $\ell < x_1$ with $\chi_d(\ell) \neq 1$

$\mathcal{S}$, $\mathcal{M}$, $\mathcal{N}$ O_j-modules of columns and of rows

W a subspace of $\mathrm{Row}(D)$

H, $H_{\ell,\iota}$ complex numbers used as factors

Z, Z', α families of complex numbers indexed by the pairs (ℓ, ι); a real number in the definition of the height

$\mathrm{cst}^{\mathrm{see}}_D$, $\mathrm{cst}^{\mathrm{vol}}_D$, $\mathrm{cst}^{\mathrm{cr}}_D$ the constants of Inputs 10, 20, 22

The data: parameters, fields and scales

- **The data of the proof: the parameters N_0 and d, the CM field $E = K(\zeta)$ and its places, the scales x, x_1, b, the ranks m, k, r, t, the order a, the comparison of sizes on the logarithmic scale, and the existence of admissible data at every large x** (unit 152)

  read: note built, structured proofs checked. 239 declarations, 213 proof lines.

The parameters and the CM field: places, Frobenius elements, the different

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The argument works over one family of number fields. The parameters $P = (N_0, d)$ are a multiple N_0 of 18480 and a prime $d \equiv N_0/2 - 1 \bmod N_0$; they give the imaginary quadratic field $K(P) = \mathbb{Q}(\sqrt{-d})$ and, for every exponent μ, the CM field $E(P, \mu)$ obtained by adjoining a root of unity of order $N_1(P, \mu) = N_0 \cdot 3^{\lfloor \log_3 \mu \rfloor + 5} \cdot 2^{\mu}$. This note sets up the arithmetic of these fields: the infinite places of $E(P, \mu)$ form a group, identified with its Galois group over $K(P)$ and with the units modulo $N_1(P, \mu)$ (Theorem A); the decomposition of a prime is read from an explicit Frobenius element (Theorem B); the ring of integers is generated by the root of unity and $(1 + \sqrt{-d})/2$, and the different is principal, generated by a purely imaginary integer the geometric mean of whose absolute values at the infinite places is the root discriminant (Theorem C). From these the note builds the data that the Weil representation over $E(P, \mu)$ needs.

What this note is. The artifact grh-compact is a body of Lean code whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. That is a claim: its authors report that Lean's kernel accepts the code; a replay of that check by the owner of this write-up was started, and the handout's record of checks gives its state; nothing was compiled for this note; no mathematician has read the proof through. This note treats one part of one unit (the folder of the data of the proof): 96 of its 239 declarations, those of the two files on the parameters, the CM field and its Weil data; the note *Admissible data* treats the rest. Every statement below was compared, argument by argument, with the Lean text, and every proof is given in full, except that results of the background library are quoted as *Inputs* with their place in the artifact. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 96 declarations.

1 The statements

The notation is that of Section 2: $P = (N_0, d)$ are parameters, μ is a natural number, $N_1(P, \mu) = N_0 \operatorname{tw}(\mu)$ is the order of the root of unity $\varsigma(P, \mu)$ of the field $E(P, \mu)$ over $K(P) = \mathbb{Q}(\sqrt{-d})$, and $\mathrm{Pl}(P, \mu)$ is the set of infinite places of $E(P, \mu)$, a group by Definition 4.4.

Theorem A (places, automorphisms, classes). Let $P = (N_0, d)$ be parameters and μ a natural number.

(a) For every infinite place $v \in \mathrm{Pl}(P,\mu)$, the automorphism $\mathrm{gal}_{P,\mu}(v)$ of $E(P,\mu)$ over $K(P)$ sends $\varsigma(P,\mu)$ to $\varsigma(P,\mu)^n$, where $n \in \{0, \dots, N_1(P,\mu)-1\}$ represents the class $\mathrm{cyc}_{P,\mu}(v) \in (\mathbb{Z}/N_1(P,\mu))^\times$.

(b) For every integer ν prime to N_0, the automorphism $\mathrm{gal}_{P,\mu}([\nu]_{P,\mu})$ sends $\varsigma(P,\mu)$ to $\varsigma(P,\mu)^\nu$.

(c) $E(P,\mu)$ has exactly $\mathrm{tw}(\mu)\,\varphi(N_0)$ infinite places, φ being Euler's function.

(d) Exactly $\mathrm{tw}(\mu)$ places $v \in \mathrm{Pl}(P,\mu)$ have class 1 modulo N_0, that is $\mathrm{cl}_P^{N_0 | N_1(P,\mu)}(v) = 1$.

Theorem B (decomposition of primes). Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number with $p \nmid N_1(P,\mu)\,d$, and w a finite place of $E(P,\mu)$ with $p \in w$. Let $v \in \mathrm{Pl}(P,\mu)$, and let $(\mathfrak{c}, e)$ be one of the two pairs $(\mathrm{id}, 1)$ and $(\text{complex conjugation}, -1)$, where $\mathfrak{c}$ is an automorphism of the ring of integers of $E(P,\mu)$ and e an integer.

(a) $v \cdot w = \mathfrak{c}^{-1}(w)$ if and only if there is a natural number n with $(v, e) = \mathrm{Fr}_\mu(p)^n$ in $\mathrm{Pl}(P,\mu) \times \mathbb{Z}$. Here $\mathfrak{c}^{-1}(w)$ is w for the first pair and the conjugate place $\overline{w}$ for the second.

(b) The norm of w is p^o, where o is the order of the Frobenius element $\mathrm{Fr}_\mu(p)$ in $\mathrm{Pl}(P,\mu) \times \mathbb{Z}$.

Theorem C (integers and the different). Let $P = (N_0, d)$ be parameters and μ a natural number; write $\mathcal{O}$ for the ring of integers of $E(P,\mu)$ and $\mathcal{O}_K$ for that of $K(P)$.

(a) Let $z \in \mathcal{O}$ be a primitive root of unity of order $N_1(P,\mu)$ and $y = \Psi'_{N_1(P,\mu)}(z)$ the value at z of the derivative of the cyclotomic polynomial of that order. Then y divides $N_1(P,\mu)$ in $\mathcal{O}$, the ideal (y) is the different of $\mathcal{O}$ over $\mathcal{O}_K$, and $\mathcal{O} = \mathcal{O}_K[z]$.

(b) The different of $\mathcal{O}$ over $\mathbb{Z}$ is the principal ideal generated by $\partial(P,\mu) \cdot \sqrt{-d}_{P,\mu}$, and also by the purely imaginary integer $\varpi(P,\mu)$ of Definition 5.5.

(c) $\prod_{v \in \mathrm{Pl}(P,\mu)} |\iota_v(\varpi(P,\mu))| = \mathrm{rd}_{E(P,\mu)}^{\#\mathrm{Pl}(P,\mu)}$, where $\mathrm{rd}_{E(P,\mu)}$ is the root discriminant of $E(P,\mu)$.

Why these parameters. The explanations of this paragraph are motivation, read from the comments of the formal text and from the places where later units use the results; they are not statements of this unit. The congruence on d does two things. First, $d \equiv -1$ modulo $N_0/2$ and $8 \mid N_0/2$ make every prime p that divides $N_1(P,\mu)$ a divisor of $(d+1)/4$, the norm of $(1+\sqrt{-d})/2$. So all these primes split in $K(P)$, into the prime above p that contains $(1+\sqrt{-d})/2$ and its conjugate, and the different of $E(P,\mu)$ over $K(P)$, which lives above these primes, can be divided between an idele and its conjugate (Lemma 7.3); this is the self-duality that the Weil representation asks for. Second, $d \not\equiv -1$ modulo N_0 itself makes the powers of d modulo N_0 avoid

-1 (Lemma 3.2). For a natural number n and a place v, the place $[-d^n]_{P,\mu} \cdot v$ then never has the class of v modulo N_0: the ramified prime d never relates two places of the same class, and later units use this. (The prime d does occur in the prime sums of the main inequality: $d^2 \equiv 1 \bmod N_0$ by the proof of Lemma 3.2.) The divisibility by $18480 = 2^4 \cdot 3 \cdot 5 \cdot 7 \cdot 11$ makes every prime below 13 split in $K(P)$ (Lemma 3.1(c)); with the factor 3^5 of $\mathrm{tw}(\mu)$ it puts the roots of unity of order $5040 = 2^4 \cdot 3^2 \cdot 5 \cdot 7$ into $E(P,\mu)$. The order of the root of unity grows with μ only by powers of 2 and 3, so that the count of places is exact (Theorem A(c), (d)) and the group of places has a large cyclic 2-part, where the note *Admissible data* builds the thick places.

2 The setting

Conventions. $\mathbb{N} = \{0, 1, 2, \dots\}$. For a number field F, a *finite place* is a nonzero prime ideal of its ring of integers, and an *infinite place* is an archimedean absolute value; the place of an embedding $\psi\colon F \to \mathbb{C}$ is $x \mapsto |\psi(x)|$. A CM field carries its complex conjugation $x \mapsto \overline{x}$, which every embedding into $\mathbb{C}$ turns into complex conjugation; it acts on the finite places, $\overline{w} = \{\overline{x} : x \in w\}$. Ψ_M is the cyclotomic polynomial of order M, the monic integral polynomial whose complex roots are the primitive roots of unity of order M. Three letters are local to this note: ψ, ψ' are embeddings of fields and homomorphisms of rings, and Ψ occurs only in Ψ_M; the columns ψ of the overview of the handout and the additive character Ψ of Chapter IV do not occur here. In a statement about a commutative ring R of characteristic p, or an integral domain R, these properties of R are part of the statement. Divisibility, floors and subtraction of natural numbers are those of $\mathbb{N}$, as in the formal text.

Definition 2.1 (Parameters)**.** *Parameters* are a pair $P = (N_0, d)$ of natural numbers such that 18480 divides N_0, d is a prime number, N_0 divides $2(d+1)$, and N_0 does not divide $d+1$. Since N_0 is even, the last two conditions say together that $d \equiv N_0/2 - 1 \bmod N_0$.

LEAN `Parameters`

Definition 2.2 (The order of the root of unity)**.** For a natural number μ put $\mathrm{tw}(\mu) = 3^{\lfloor \log_3 \mu \rfloor + 5} \cdot 2^\mu$, where $\lfloor \log_3 0 \rfloor = 0$. For parameters $P = (N_0, d)$ and a natural number μ put

$$N_1(P,\mu) = N_0 \cdot \mathrm{tw}(\mu), \qquad M_\omega(P,\mu) = (N_0\, d)^{\mu+6},$$

and let $K(P) = \mathbb{Q}(\mathrm{i}\sqrt{d}) \subset \mathbb{C}$ be the imaginary quadratic field $\mathbb{Q}(\sqrt{-d})$, as a subfield of the complex numbers. Its quadratic character $\chi_{K(P)}$ is, on the integers, the Legendre symbol modulo d (so $\chi_{K(P)}(d) = 0$); in the formal text it is a function of d.

LEAN `towerDeg` · `Parameters.N₁` · `Parameters.K` · `Parameters.Mω`

The power of 3 in $\mathrm{tw}(\mu)$ lies between 81μ and 243μ for $\mu \geq 1$. The number $M_\omega(P,\mu)$ will be the order of certain characters of residue fields in later units; here only Lemma 3.1(d) concerns it.

Definition 2.3 (The CM field, its places, its root of unity)**.** Let $P = (N_0, d)$ be parameters and μ a natural number. $E(P,\mu)$ is the splitting field over $K(P)$ of the cyclotomic polynomial $\Psi_{N_1(P,\mu)}$ (in it $X^{N_1(P,\mu)} - 1$ splits as well), and $\varsigma(P,\mu) \in E(P,\mu)$

is a chosen primitive root of unity of order $N_1(P,\mu)$; so $E(P,\mu) = K(P)(\varsigma(P,\mu))$. $\mathrm{Pl}(P,\mu)$ is the set of infinite places of $E(P,\mu)$. Finally

$$\Omega(P,\mu) = \exp(\mathrm{cs}(d)) \cdot \frac{2\pi}{\mathrm{rd}_{E(P,\mu)}},$$

where $\mathrm{rd}_{E(P,\mu)}$ is the root discriminant of $E(P,\mu)$ (the absolute value of its discriminant, raised to the power one over its degree) and $\mathrm{cs}(d)$ is Euler's constant minus the real part of the logarithmic derivative at 1 of the entire Dirichlet series of $\chi_{K(P)}$ (its L-function made entire) (a definition of the library, unit 106).

LEAN Parameters.E · Parameters.Φ · Parameters.ζ · Parameters.isPrimitiveRoot_zeta · Parameters.bigOmega

The number $\Omega(P,\mu)$ is a period: later units measure theta functions against it. This unit only defines it.

3 The parameters

Lemma 3.1 (Arithmetic of the parameters)**.** *Let $P = (N_0, d)$ be parameters and μ a natural number.*

(a) $d \equiv 7 \bmod 8$, and $64 < d$.

(b) If p is a prime number dividing $N_1(P,\mu)$, then p divides $(d+1)/4$, and $\chi_{K(P)}(p) = 1$.

(c) If p is a prime number with $\chi_{K(P)}(p) \neq 1$, then $13 \leq p$.

(d) $N_1(P,\mu)$ and d are coprime; $2^{\mu+1}$ divides $N_1(P,\mu)$; and $N_1(P,\mu)\,d$ divides $M_\omega(P,\mu)$.

Proof. (a) 16 divides N_0 and N_0 divides $2(d+1)$, so $8 \mid d+1$. Also $N_0 \neq 0$, because 0 divides only 0, so $18480 \leq N_0 \leq 2(d+1)$.

(b) The primes 2 and 3 divide N_0, so p divides N_0, hence p divides $2(d+1) = 8 \cdot \frac{d+1}{4}$ (the quotient is exact by (a)). Thus p divides 8 or $(d+1)/4$; in the first case $p = 2$, and 2 divides $(d+1)/4$ by (a). So $4p$ divides $d+1$. Now $\chi_{K(P)}(p)$ is the Jacobi symbol of p over the odd number d, and a Jacobi symbol with upper entry p depends only on the lower entry modulo $4p$. As $d \equiv 4p-1 \bmod 4p$, it equals the symbol of p over $4p-1$, which is the symbol of $4p$ over $4p-1$ because 4 is a square, that is the symbol of 1 over $4p-1$, which is 1.

(c) The primes below 13 divide 18480, hence $N_1(P,0)$, and (b) applies with the exponent 0.

(d) If the prime d divided $N_1(P,\mu)$, then $\chi_{K(P)}(d) = 1$ by (b), but $\chi_{K(P)}(d) = 0$. Next $2 \mid N_0$ and $2^\mu \mid \mathrm{tw}(\mu)$. Finally $\lfloor \log_3 \mu \rfloor \leq \mu$, so $\mathrm{tw}(\mu)$ divides $6^{\mu+5}$, which divides $(N_0 d)^{\mu+5}$ because $6 \mid N_0$; multiplying by $N_0\,d$ gives the claim. □

LEAN Parameters.instHeegD · Parameters.lt_d · Parameters.dvd_norm_c₀ · Parameters.chiK_eq_one_of_dvd · Parameters.thirteen_le_of_chiK_ne_one · Parameters.coprime_N₁_d · Parameters.two_pow_dvd_N₁ · Parameters.N₁_mul_d_dvd_M_omega

Lemma 3.2 (Powers of d modulo N_0)**.** *Let $P = (N_0, d)$ be parameters and n a natural number. Then $d^n \not\equiv -1 \bmod N_0$.*

Proof. In $\mathbb{Z}/N_0$ one has $2(d+1)=0$ and $d+1\neq 0$. As d is odd, $d-1=2i$ with an integer i, and $d^2-1=i\cdot 2(d+1)=0$. So every power of d is 1 or d. Here $d\neq -1$ by assumption, and $1\neq -1$, since $2=0$ would give $d+1=2(i+1)=0$. □

LEAN `Parameters.pow_d_ne_neg_one`

4 The field and its places

Lemma 4.1 (The cyclotomic polynomial stays irreducible)**.** *Let $P=(N_0,d)$ be parameters and μ a natural number. Then $\Psi_{N_1(P,\mu)}$ is irreducible over $K(P)$.*

Proof. Let F be the cyclotomic field of order d. As d is a prime with $d\equiv 3 \bmod 4$ (Lemma 3.1(a)), $K(P)$ embeds into F by Input (I0) of Section 5. It suffices that the polynomial is irreducible over F. Let x be a root of it in an extension of F. The minimal polynomial of x over F divides $\Psi_{N_1(P,\mu)}$, and its degree is $[F(x):F]$. The field $F(x)$ contains roots of unity of the coprime orders $N_1(P,\mu)$ and d (Lemma 3.1(d)), hence of order $N_1(P,\mu)d$, so its degree over $\mathbb{Q}$ is at least $\varphi(d)\,\varphi(N_1(P,\mu))$ by the irreducibility of cyclotomic polynomials over $\mathbb{Q}$. As $[F:\mathbb{Q}]=\varphi(d)$, we get $[F(x):F]\geq\varphi(N_1(P,\mu))$, the degree of $\Psi_{N_1(P,\mu)}$. So $\Psi_{N_1(P,\mu)}$ is the minimal polynomial of x. □

LEAN `Parameters.irreducible_cyclotomic`

Lemma 4.2 (The CM field lies in a cyclotomic field)**.** *Let $P=(N_0,d)$ be parameters and μ a natural number. There is an embedding of fields of $E(P,\mu)$ into the cyclotomic field of order $N_1(P,\mu)\,d$. Consequently $E(P,\mu)$ is abelian over $\mathbb{Q}$ and over $K(P)$, it is totally complex, and it is a CM field.*

Proof. The cyclotomic field of order $N_1(P,\mu)d$ contains a primitive root of unity of order d, hence a copy of $K(P)$ by (I0), and over it $\Psi_{N_1(P,\mu)}$ splits; a splitting field embeds into every extension in which the polynomial splits. A subfield of an abelian extension of $\mathbb{Q}$ is abelian over $\mathbb{Q}$, and $E(P,\mu)$ is totally complex because it contains the imaginary quadratic field $K(P)$. A totally complex abelian number field is a CM field: because the Galois group is abelian, complex conjugation is the same automorphism for every embedding into $\mathbb{C}$, and its fixed field is totally real. □

LEAN `Parameters.toCycloField`; the consequences are instances without names, stated after it in the formal text.

Lemma 4.3 (An embedding over the quadratic field is determined by its place)**.** *Let $P=(N_0,d)$ be parameters, μ a natural number, and ψ, ψ' two embeddings of $E(P,\mu)$ into $\mathbb{C}$ that are the identity on $K(P)$. If ψ and ψ' have the same infinite place, then $\psi=\psi'$.*

Proof. Two embeddings with the same place are equal or complex conjugate. If ψ' were the conjugate of ψ, then every $x\in K(P)$ would be equal to its complex conjugate, which fails for $\mathrm{i}\sqrt{d}$. □

LEAN `Parameters.algHom_eq_of_mk_eq`

Definition 4.4 (The group of places and its three descriptions)**.** Let $P=(N_0,d)$ be parameters and μ a natural number. Fix an embedding $\iota_1 : E(P,\mu)\to\mathbb{C}$ that is the

identity on $K(P)$ (the formal text takes the one that the algebraic closedness of $\mathbb{C}$ provides). The map

$$\mathrm{Gal}(E(P,\mu)/K(P)) \longrightarrow \mathrm{Pl}(P,\mu), \qquad \gamma \longmapsto \text{the place of } \iota_1 \circ \gamma,$$

is a bijection: it is injective by Lemma 4.3, and surjective because the Galois group permutes transitively the places of $E(P,\mu)$ above the one infinite place of $K(P)$. The set $\mathrm{Pl}(P,\mu)$ is given the structure of a commutative group that makes this bijection an isomorphism; its unit element is the place of ι_1.

(i) $\mathrm{gal}_{P,\mu}\colon \mathrm{Pl}(P,\mu) \to \mathrm{Gal}(E(P,\mu)/K(P))$ is the inverse isomorphism.

(ii) $\mathrm{cyc}_{P,\mu}\colon \mathrm{Pl}(P,\mu) \to (\mathbb{Z}/N_1(P,\mu))^\times$ is $\mathrm{gal}_{P,\mu}$ followed by the cyclotomic character, which is an isomorphism by Lemma 4.1.

(iii) For an integer ν, the place $[\nu]_{P,\mu} \in \mathrm{Pl}(P,\mu)$ is the one with $\mathrm{cyc}_{P,\mu}([\nu]_{P,\mu}) = \nu \bmod N_1(P,\mu)$ if ν is prime to $N_1(P,\mu)$, and the unit element otherwise.

(iv) For a natural number m' with $m' \mid N_1(P,\mu)$, the homomorphism

$$\mathrm{cl}_P^{m'|N_1(P,\mu)}\colon \mathrm{Pl}(P,\mu) \longrightarrow (\mathbb{Z}/m')^\times$$

is $\mathrm{cyc}_{P,\mu}$ followed by reduction modulo m': the *class modulo* m' of a place. (In the formal text its explicit arguments are P and the proof of the divisibility; the divisibility is written in the place of that proof.)

(v) For $v \in \mathrm{Pl}(P,\mu)$ the *chosen embedding at* v is $\iota_v = \iota_1 \circ \mathrm{gal}_{P,\mu}(v)$; its place is v. This is the CM type of $E(P,\mu)$ that all later units use.

LEAN `Parameters.galOfPlace` · `Parameters.placeMulEquiv` · `Parameters.placeOfInt` · `Parameters.placeClass`; the group structure and the CM type are instances without names.

Lemma 4.5 (The dictionary)**.** *Let $P = (N_0, d)$ be parameters and μ a natural number; let $v, v' \in \mathrm{Pl}(P,\mu)$, let ν be an integer and i a natural number.*

(a) $\iota_v(x) = x$ *for every* $x \in K(P)$*, and* $\iota_{v\,v'}(x) = \iota_v(\mathrm{gal}_{P,\mu}(v')(x))$ *for every* $x \in E(P,\mu)$*.*

(b) $\overline{\varsigma(P,\mu)} = \varsigma(P,\mu)^{-1}$*.*

(c) $[\nu]_{P,\mu}^{i} = [\nu^i]_{P,\mu}$*.*

(d) If ν is prime to N_0, then for every natural number m' with $m' \mid N_1(P,\mu)$ the class $\mathrm{cl}_P^{m'|N_1(P,\mu)}([\nu]_{P,\mu})$ is the class of ν modulo m'.

(e) $\mathrm{cl}_P^{N_0|N_1(P,\mu)}([\nu]_{P,\mu}) = -1$ *if and only if* $\nu \equiv -1 \bmod N_0$*.*

Proof. (a) holds by the definition of ι_v, since $\mathrm{gal}_{P,\mu}$ is a homomorphism into a group of automorphisms over $K(P)$. (b) The injective map ι_1 commutes with conjugation and sends $\varsigma(P,\mu)$ to a complex number of absolute value 1, whose conjugate is its inverse. (c) If ν is prime to $N_1(P,\mu)$, both sides have the class ν^i. If not, then ν^i is not prime to $N_1(P,\mu)$ for $i \geq 1$ and both sides are the unit element, and for $i = 0$ both sides are the unit element as well. (d) The numbers N_0 and $N_1(P,\mu)$ have the same prime divisors, so ν is prime to $N_1(P,\mu)$ and the class of $[\nu]_{P,\mu}$ is ν. (e) If the class is -1, then ν is prime to $N_1(P,\mu)$, because the unit element has class $1 \neq -1$ (Lemma 3.2 with $n = 0$); then (d) applies. Conversely $\nu \equiv -1 \bmod N_0$ is prime to N_0, and (d) applies. □

LEAN Parameters.phi_algebraMap · Parameters.phi_mul · Parameters.star_ζ · Parameters.placeOfInt_pow · Parameters.placeClass_placeOfInt · Parameters.placeClass_placeOfInt_eq_neg_one

Proof of Theorem A. (a) is the definition of the cyclotomic character, and (b) follows from (a) and Lemma 4.5(d): the exponent n represents ν modulo $N_1(P,\mu)$, and $\varsigma(P,\mu)$ has that order. (c) By Definition 4.4 the number of places is the order of $(\mathbb{Z}/N_1(P,\mu))^\times$, which is the degree of $\Psi_{N_1(P,\mu)}$. For a prime p dividing M one has $\Psi_M(X^{p^k}) = \Psi_{Mp^k}(X)$ (induction on k); as 2 and 3 divide N_0, this gives $\Psi_{N_1(P,\mu)}(X) = \Psi_{N_0}(X^{\mathrm{tw}(\mu)})$, of degree $\mathrm{tw}(\mu)\,\varphi(N_0)$. (d) The places of class 1 modulo N_0 form the kernel of the reduction from $(\mathbb{Z}/N_1(P,\mu))^\times$ onto $(\mathbb{Z}/N_0)^\times$, whose order is the quotient of the two orders. □

Definition 4.6 (The permutation of the places by an automorphism of $\mathbb{C}$)**.** Let $P = (N_0, d)$ be parameters, μ a natural number and σ a field automorphism of $\mathbb{C}$ that is the identity on $K(P)$. Then $\mathrm{perm}_\mu(\sigma)$ is the permutation of $\mathrm{Pl}(P,\mu)$ that multiplies every place, on the left, by the place of the embedding $\sigma \circ \iota_1$. (Its explicit arguments in the formal text are μ and σ; the parameters are read from σ.)

LEAN Parameters.placePerm

Lemma 4.7. *Let $P = (N_0, d)$ be parameters, μ a natural number, σ a field automorphism of $\mathbb{C}$ that is the identity on $K(P)$, $v \in \mathrm{Pl}(P,\mu)$ and $x \in E(P,\mu)$. Then $\sigma(\iota_v(x)) = \iota_{v^*}(x)$ with $v^* = \mathrm{perm}_\mu(\sigma)(v)$.*

Proof. Let u be the place of $\sigma \circ \iota_1$. The embeddings $\sigma \circ \iota_1$ and ι_u are the identity on $K(P)$ and have the same place, so they are equal (Lemma 4.3). Hence $\sigma(\iota_v(x)) = \iota_u(\mathrm{gal}_{P,\mu}(v)(x)) = \iota_{u\,v}(x)$ by Lemma 4.5(a). □

LEAN Parameters.placePerm_spec

Lemma 4.8 (Roots of unity, and the norm to the quadratic field)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number and $y \in E(P,\mu)$.*

(a) If y is a root of unity, then there is a natural number $n < N_1(P,\mu)$ with $\varsigma(P,\mu)^n = y$.

(b) $\prod_{v \in \mathrm{Pl}(P,\mu)} \iota_v(y)$ is the norm of y from $E(P,\mu)$ to $K(P) \subset \mathbb{C}$.

Proof. (a) It suffices that $y^{N_1(P,\mu)} = 1$. By Lemma 4.2 the roots of unity of $E(P,\mu)$ embed into those of the cyclotomic field of the even order $N_1(P,\mu)d$, a group of that order; so $z = y^{N_1(P,\mu)}$ satisfies $z^d = 1$. If $z \neq 1$, then z has order d, and as in the proof of Lemma 4.1 the degree of $E(P,\mu)$ over $\mathbb{Q}$ is at least $\varphi(d)\,\varphi(N_1(P,\mu))$. That degree is twice the number of infinite places, $2\,\varphi(N_1(P,\mu))$, so $d - 1 \leq 2$, against $d > 64$. (b) The norm is the product of the conjugates $\gamma(y)$ over the Galois group; apply ι_1, which is the identity on $K(P)$. □

LEAN Parameters.exists_zeta_pow_eq · Parameters.prod_phi_eq_norm

5 The different

Definition 5.1 (Four integers)**.** Let $P = (N_0, d)$ be parameters and μ a natural number, and let $\mathcal{O}$ be the ring of integers of $E(P,\mu)$. The root of unity $\varsigma(P,\mu)$ lies in $\mathcal{O}$ (the formal text has a second name for it as an element of $\mathcal{O}$, written here in the same way). $c_0(P,\mu) \in \mathcal{O}$ is the integer $(1+\sqrt{-d})/2$ of $K(P)$, and $\sqrt{-d}_{P,\mu} = 2\,c_0(P,\mu) - 1$ is the square root of $-d$ that lies in $K(P) \subset \mathbb{C}$ on the positive imaginary axis. Finally $\partial(P,\mu) = \Psi'_{N_1(P,\mu)}(\varsigma(P,\mu)) \in \mathcal{O}$.

LEAN `Parameters.zetaInt` · `Parameters.c₀InE` · `Parameters.sqrtNegDInE` · `Parameters.relDifferentGen` · `Parameters.coe_zetaInt` · `Parameters.isPrimitiveRoot_zetaInt` · `Parameters.coe_sqrtNegDInE`

Lemma 5.2. *Let $P = (N_0, d)$ be parameters and μ, n natural numbers. Then, in the ring of integers of $E(P,\mu)$: $\overline{\sqrt{-d}_{P,\mu}} = -\sqrt{-d}_{P,\mu}$, and $\sqrt{-d}_{P,\mu}$ divides d; $c_0(P,\mu)\,(1 - c_0(P,\mu)) = (d+1)/4$ and $\overline{c_0(P,\mu)} = 1 - c_0(P,\mu)$; and $\overline{\varsigma(P,\mu)}^{\,n}\,\varsigma(P,\mu)^n = 1$.*

Proof. The square of $\sqrt{-d}_{P,\mu}$ is $-d$, its conjugate is the other root $-\sqrt{-d}_{P,\mu}$, and $c_0(P,\mu) = (1+\sqrt{-d}_{P,\mu})/2$. The last identity is Lemma 4.5(b). □

Inputs. In (I0) to (I1′), d is any prime number with the congruence stated. (I0), unit 106: for a prime $d \equiv 3 \bmod 4$, the field $\mathbb{Q}(\sqrt{-d})$ embeds into every field of characteristic 0 that contains a primitive root of unity of order d (a quadratic Gauss sum). (I1), unit 106: for a prime $d \equiv 7 \bmod 8$ the different of $\mathbb{Q}(\sqrt{-d})$ over $\mathbb{Q}$ is generated by $\sqrt{-d}$, and the ring of integers is $\mathbb{Z}[(1+\sqrt{-d})/2]$. (I1′), unit 106: let $d \equiv 7 \bmod 8$ be prime, p an odd prime number, ψ' a homomorphism from the ring of integers of $\mathbb{Q}(\sqrt{-d})$ to a commutative ring R of characteristic p, n a natural number and $x \in R$. Then $x = \psi'((1+\sqrt{-d})/2)^{p^n}$ if and only if $2x - 1 = \chi(p)^n\,\psi'(\sqrt{-d})$, where $\chi(p)$ is the Legendre symbol of p modulo d (Euler's criterion with the law of quadratic reciprocity). (I2), unit 10: let $F \subset F'$ be number fields with rings of integers $\mathcal{O}_F \subset \mathcal{O}_{F'}$, let $z \in \mathcal{O}_{F'}$ generate F' over F, and let a polynomial over $\mathcal{O}_F$ vanish at z and have derivative y at z; if the ideal (y) divides the different of $\mathcal{O}_{F'}$ over $\mathcal{O}_F$, then that different is (y) and $\mathcal{O}_{F'} = \mathcal{O}_F[z]$. (I3), unit 10: a prime ideal whose square contains a prime number divides the different over $\mathbb{Z}$.

References, as the catalogue of the write-up and the dossier of the unit record them; none was opened for this note. For (I3): K. Conrad [1], Theorem 4.13 and its proof, of which (I3) is a consequence (the lower bound for the exponent of the different at a ramified prime; the reading agent's record), and Neukirch [2], Ch. III, §2, place not confirmed. For (I1): Neukirch [2], Ch. I, place not confirmed. For (I2): Serre [3], Ch. III, place not confirmed. For (I0) and (I1′) the catalogue names no work. From Mathlib we use that the ring of integers of $\mathbb{Q}(z)$, for a root of unity z, is $\mathbb{Z}[z]$, and that the different is multiplicative in a tower of number fields.

Proof of Theorem C(a). Write $X^{N_1(P,\mu)} - 1 = \Psi_{N_1(P,\mu)} \cdot Q$ with an integral polynomial Q. Differentiating and evaluating at z gives $y\,Q(z) = N_1(P,\mu)\,z^{N_1(P,\mu)-1}$, so

$y\,Q(z)\,z = N_1(P,\mu)$: thus y divides $N_1(P,\mu)$. The subfield $\mathbb{Q}(z)$ is the cyclotomic field of order $N_1(P,\mu)$; its ring of integers is $\mathbb{Z}[z]$, so its different over $\mathbb{Q}$ is generated by y. By (I1) the different of $K(P)$ over $\mathbb{Q}$ is generated by $\sqrt{-d}_{P,\mu}$, which divides d (Lemma 5.2); as $N_1(P,\mu)$ and d are coprime (Lemma 3.1(d)), the ideals (y) and $(\sqrt{-d}_{P,\mu})$ of $\mathcal{O}$ are coprime. The different of $\mathcal{O}$ over $\mathbb{Z}$ is a multiple of (y), by transitivity through $\mathbb{Q}(z)$, and it is the product of the different of $\mathcal{O}$ over $\mathcal{O}_K$ and $(\sqrt{-d}_{P,\mu})$, by transitivity through $K(P)$. Hence (y) divides the different of $\mathcal{O}$ over $\mathcal{O}_K$, and (I2), for the polynomial $\Psi_{N_1(P,\mu)}$, gives both remaining assertions. (I2) applies because z generates $E(P,\mu)$ over $K(P)$: the root of unity $\varsigma(P,\mu)$ is a power of z, both being primitive of order $N_1(P,\mu)$. □

LEAN `Parameters.relDifferent_spec`

Lemma 5.3. *Let $P = (N_0, d)$ be parameters and μ a natural number. Then $\partial(P,\mu)$ divides $N_1(P,\mu)$ in the ring of integers of $E(P,\mu)$, so $\partial(P,\mu) \neq 0$; and $N_1(P,\mu)\,d$ lies in the different of that ring over $\mathbb{Z}$.*

Proof. The first assertion is Theorem C(a) for $z = \varsigma(P,\mu)$. By Theorem C(a) and transitivity the different over $\mathbb{Z}$ is generated by $\partial(P,\mu)\cdot\sqrt{-d}_{P,\mu}$, which is the first half of Theorem C(b); this product divides $N_1(P,\mu)\,d$ by Lemma 5.2. □

Lemma 5.4 (A unit that makes the generator real)**.** *Let $P = (N_0, d)$ be parameters and μ a natural number. There is an integer u_0 of $E(P,\mu)$ with $\overline{u_0}\,u_0 = 1$ and $\overline{u_0\,\partial(P,\mu)} = u_0\,\partial(P,\mu)$.*

Proof. The derivative of a product $\prod(X-x)$ of distinct linear factors at one of its roots is the product of the differences of that root and the others. So $\partial(P,\mu)$ is the product of the differences $\varsigma(P,\mu) - x$ over the primitive roots of unity $x \neq \varsigma(P,\mu)$ of order $N_1(P,\mu)$. Each of them is $x = \varsigma(P,\mu)^{\,l}$ with l prime to $N_1(P,\mu)$, hence odd, $l = 2i+1$, and

$$\varsigma(P,\mu) - \varsigma(P,\mu)^{\,2i+1} = \varsigma(P,\mu)^{\,i+1}\bigl(\varsigma(P,\mu)^{-i} - \varsigma(P,\mu)^{\,i}\bigr).$$

The second factor changes sign under conjugation (Lemma 4.5(b)). As 4 divides $N_1(P,\mu)$, the ring of integers contains a square root i_* of -1, and $\overline{\mathrm{i}_*} = -\mathrm{i}_*$. Put $u_x = \mathrm{i}_*\,\overline{\varsigma(P,\mu)}^{\,i+1}$; then $\overline{u_x}\,u_x = 1$ by Lemma 5.2, and $u_x\,(\varsigma(P,\mu) - x) = \mathrm{i}_*\bigl(\varsigma(P,\mu)^{-i} - \varsigma(P,\mu)^{\,i}\bigr)$ is fixed by conjugation. The product u_0 of the u_x has the two properties. (The formal proof is this induction over the factors.) □

LEAN `Parameters.exists_unit_mul_relDifferentGen_real`

Definition 5.5 (The purely imaginary generator of the different)**.** Let $P = (N_0, d)$ be parameters and μ a natural number. With an integer u_0 chosen as in Lemma 5.4, $\varpi(P,\mu) = u_0\cdot\partial(P,\mu)\cdot\sqrt{-d}_{P,\mu}$.

LEAN `Parameters.ϖ`

Lemma 5.6. *Let $P = (N_0, d)$ be parameters, μ a natural number and $v \in \mathrm{Pl}(P,\mu)$. Then $\overline{\varpi(P,\mu)} = -\varpi(P,\mu)$, and $|\iota_v(\varpi(P,\mu))| = |\iota_v(\partial(P,\mu))|\cdot\sqrt{d}$.*

Proof. $u_0\,\partial(P,\mu)$ is fixed by conjugation and $\sqrt{-d}_{P,\mu}$ changes sign. Further $|\iota_v(u_0)|^2 = \iota_v(\overline{u_0}\,u_0) = 1$ and $|\iota_v(\sqrt{-d}_{P,\mu})| = \sqrt{d}$. □

LEAN Parameters.star_ϖ · Parameters.infinitePlace_apply_varpi

Proof of Theorem C(b), (c). The first half of (b) was shown with Lemma 5.3; the second follows because u_0 is a unit. For (c), all infinite places of $E(P,\mu)$ are complex, so the square of the product in question is the absolute value of the norm of $\varpi(P,\mu)$ to $\mathbb{Q}$, that is the absolute norm of the different, that is the absolute value of the discriminant, which is $\mathrm{rd}_{E(P,\mu)}$ to the power twice the number of infinite places. Take square roots. □

6 Frobenius elements

Definition 6.1 (The action on finite places; the Frobenius element)**.** Let $P=(N_0,d)$ be parameters and μ a natural number, and let $\mathcal{O}$ be the ring of integers of $E(P,\mu)$. For $v\in\mathrm{Pl}(P,\mu)$ let $\mathrm{gal}_v\colon\mathcal{O}\to\mathcal{O}$ be the restriction of $\mathrm{gal}_{P,\mu}(v)$ (its one explicit argument in the formal text is v). The group $\mathrm{Pl}(P,\mu)$ acts on the finite places of $E(P,\mu)$ by $v\cdot w=\{x\in\mathcal{O}:\mathrm{gal}_v(x)\in w\}$. For a natural number p,

$$\mathrm{Fr}_\mu(p)=\left([\chi_{K(P)}(p)\,p]_{P,\mu},\ \chi_{K(P)}(p)\right)\in\mathrm{Pl}(P,\mu)\times\mathbb{Z},$$

and powers of such pairs are taken componentwise. (The parameters P are an implicit argument of the formal definition; the notation shows the two explicit ones, the exponent μ and p.)

LEAN Parameters.galOfPlaceInt · Parameters.frobElem · Parameters.coe_galOfPlaceInt · Parameters.mem_smul; the action is an instance without a name.

Setting 6.2. $P=(N_0,d)$ are parameters, μ is a natural number, $\mathcal{O}$ is the ring of integers of $E(P,\mu)$, p is a prime number, $v\in\mathrm{Pl}(P,\mu)$, and $(\mathfrak{c},e)$ is one of the two pairs $(\mathrm{id},1)$ and $(\text{complex conjugation},-1)$, where $\mathfrak{c}$ is an automorphism of the ring $\mathcal{O}$ and e an integer. Further R is a commutative ring of characteristic p, $\psi\colon\mathcal{O}\to R$ is a homomorphism of rings, and n is a natural number.

Lemma 6.3 (A Frobenius congruence is tested on two generators)**.** *In Setting 6.2 assume $p\nmid N_1(P,\mu)$. Then $\psi(\mathrm{gal}_v(x))=\psi(\mathfrak{c}(x))^{p^n}$ holds for all $x\in\mathcal{O}$ if and only if both*

$$\psi(\mathrm{gal}_v(\varsigma(P,\mu)))=\psi(\mathrm{gal}_u(\varsigma(P,\mu)))\quad\text{with } u=[e\,p^n]_{P,\mu}$$

and

$$\chi_{K(P)}(p)^n\,e\,\psi(\sqrt{-d}_{P,\mu})=\psi(\sqrt{-d}_{P,\mu}).$$

Proof. Both $x\mapsto\psi(\mathrm{gal}_v(x))$ and $x\mapsto\psi(\mathfrak{c}(x))^{p^n}$ are homomorphisms of rings, the second because R has characteristic p. By (I1) and Theorem C(a) the ring $\mathcal{O}$ is generated by $\varsigma(P,\mu)$ and $c_0(P,\mu)$, so the two maps agree if and only if they agree at these two elements. At the root of unity: $\mathfrak{c}$ raises it to the power e (Lemma 4.5(b)), and $e\,p^n$ is prime to N_0 because $p\nmid N_1(P,\mu)$, so $\mathfrak{c}(\varsigma(P,\mu))^{p^n}=\mathrm{gal}_u(\varsigma(P,\mu))$ by Theorem A(b). At $c_0(P,\mu)$, which gal_v fixes: here $d\equiv7\bmod8$ and p is odd (Lemma 3.1(a) and the hypothesis $p\nmid N_1(P,\mu)$), so (I1′) applies, with $\chi(p)=\chi_{K(P)}(p)$, to the restriction ψ' of $\psi\circ\mathfrak{c}$ to the integers of $K(P)$, where $\psi'(\sqrt{-d})=e\,\psi(\sqrt{-d}_{P,\mu})$, and to $x=\psi(c_0(P,\mu))$, where $2x-1=\psi(\sqrt{-d}_{P,\mu})$. This turns the condition at $c_0(P,\mu)$ into the second equation. □

LEAN Parameters.frob_ext · Parameters.isCoprime_N₀_of_not_dvd

Lemma 6.4 (Frobenius congruences and powers of the Frobenius element)**.** *In Setting 6.2 assume that R is an integral domain and that $p \nmid N_1(P,\mu)\,d$. Then $\psi(\mathrm{gal}_v(x)) = \psi(\mathfrak{c}(x))^{p^n}$ holds for all $x \in \mathcal{O}$ if and only if $(v,e) = \mathrm{Fr}_\mu(p)^n$ in $\mathrm{Pl}(P,\mu) \times \mathbb{Z}$.*

Proof. Use Lemma 6.3. The image of the root of unity in the domain R is a root of the cyclotomic polynomial of an order that is not zero in R, so its powers with exponents below that order are distinct; by Theorem A(a) the first condition says that v and u have the same class, that is $v = [e\,p^n]_{P,\mu}$. In the second condition $\psi(\sqrt{-d}_{P,\mu})$ can be cancelled, because its square $-d$ is not zero in R; it says $\chi_{K(P)}(p)^n\,e = 1$ in R, hence $e = \chi_{K(P)}(p)^n$, as both are ± 1 and $p \neq 2$. Together with Lemma 4.5(c) the two conditions say $v = [\chi_{K(P)}(p)\,p]^n_{P,\mu}$ and $e = \chi_{K(P)}(p)^n$. □

LEAN Parameters.frob_iff_eq_frobElem_pow

Proof of Theorem B. The residue ring $\mathcal{O}/w$ is a finite field of characteristic p; let ψ be the reduction. (a) If $v \cdot w = \mathfrak{c}^{-1}(w)$, then $\mathrm{gal}_v \circ \mathfrak{c}^{-1}$ maps w into itself and induces an endomorphism of the finite field, which is a power of the Frobenius map: for some n, $\psi(\mathrm{gal}_v(x)) = \psi(\mathfrak{c}(x))^{p^n}$ for all x, and Lemma 6.4 gives $(v,e) = \mathrm{Fr}_\mu(p)^n$. Conversely, such an n gives that congruence by Lemma 6.4, and then $x \in v \cdot w$ if and only if $\mathfrak{c}(x)^{p^n} \in w$, if and only if $\mathfrak{c}(x) \in w$. (b) The norm of w is p^i for the residue degree i. By Lemma 6.4, for the unit place and the first pair, $\mathrm{Fr}_\mu(p)^n = 1$ if and only if $x^{p^n} = x$ on the residue field, if and only if i divides n. So i is the order of $\mathrm{Fr}_\mu(p)$. □

LEAN Parameters.smul_eq_iff_exists_frobElem_pow · Parameters.q_eq_pow

Lemma 6.5 (No ramification)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number with $p \nmid N_1(P,\mu)\,d$ and w a finite place of $E(P,\mu)$ with $p \in w$. Then $p \notin w^2$, and p has valuation exactly 1 at w.*

Proof. If $p \in w^2$, then w divides the different by (I3), which contains $N_1(P,\mu)\,d$ (Lemma 5.3); a natural number in w is divisible by p. □

LEAN Parameters.natCast_notMem_sq · Parameters.intValuation_p

Lemma 6.6 (Transitivity up to conjugation)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number, and w, w' finite places of $E(P,\mu)$ with $p \in w$ and $p \in w'$. Then there is $v \in \mathrm{Pl}(P,\mu)$ with $v \cdot w = w'$ or $\overline{v \cdot w} = w'$.*

Proof. The Galois group of $E(P,\mu)$ over $\mathbb{Q}$ permutes the primes above p transitively: there is an automorphism γ with $\gamma(w') = w$, that is $w' = \{x : \gamma(x) \in w\}$. Let v be the place of the embedding $\iota_1 \circ \gamma$. The embedding $\iota_v = \iota_1 \circ \mathrm{gal}_{P,\mu}(v)$ has the same place, so γ is $\mathrm{gal}_{P,\mu}(v)$, or $\mathrm{gal}_{P,\mu}(v)$ followed by complex conjugation, which commutes with $\mathrm{gal}_{P,\mu}(v)$ because $E(P,\mu)$ is abelian over $\mathbb{Q}$ (Lemma 4.2). In the first case $w' = v \cdot w$ by the definition of the action, which takes preimages; in the second $w' = \{x : \overline{\mathrm{gal}_v(x)} \in w\} = \{x : \mathrm{gal}_v(\overline{x}) \in w\} = \overline{v \cdot w}$. □

LEAN Parameters.exists_smul_eq_or_star

Lemma 6.7 (Primes inert in the quadratic field)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number and p a prime number with $\chi_{K(P)}(p) = -1$. Then $p \nmid N_1(P,\mu)\,d$. Let moreover w be a finite place of $E(P,\mu)$ with $p \in w$, and $v \in \mathrm{Pl}(P,\mu)$. Then*

$v \cdot w = w$ if and only if $v = [-p]^n_{P,\mu}$ for an even natural number n; $v \cdot w = \overline{w}$ if and only if $v = [-p]^n_{P,\mu}$ for an odd n; and the norm of w is p to the least common multiple of 2 and the order of $[-p]_{P,\mu}$ in $\mathrm{Pl}(P,\mu)$.

Proof. The primes dividing $N_1(P,\mu)\,d$ have $\chi_{K(P)} = 1$ or 0 (Lemma 3.1(b)). Here $\mathrm{Fr}_\mu(p) = ([-p]_{P,\mu}, -1)$, and Theorem B applies with either pair. □

LEAN `Parameters.not_dvd_N₁_mul_d_of_inert` · `Parameters.smul_eq_iff_inert` · `Parameters.smul_eq_star_iff_inert` · `Parameters.q_eq_inert`

Lemma 6.8 (Numbers congruent to 1 modulo the conductor)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number and p a natural number with $p \equiv 1 \bmod N_1(P,\mu)\,d$. Then $\chi_{K(P)}(p) = 1$ and $\mathrm{Fr}_\mu(p) = 1$. If moreover p is a prime number, then $p \nmid N_1(P,\mu)\,d$; and for every finite place w of $E(P,\mu)$ with $p \in w$ and every $v \in \mathrm{Pl}(P,\mu)$: $v \cdot w \neq \overline{w}$; $v \cdot w = w$ if and only if $v = 1$; and the norm of w is p.*

Proof. $p \equiv 1$ modulo d and modulo $N_1(P,\mu)$, so the symbol is 1 and $[p]_{P,\mu}$ is the unit element. A prime dividing the modulus would divide 1. The rest is Theorem B with $\mathrm{Fr}_\mu(p) = 1$. □

LEAN `Parameters.chiK_eq_one_of_modEq_one` · `Parameters.frobElem_eq_one` · `Parameters.not_dvd_N₁_mul_d_of_modEq_one` · `Parameters.smul_ne_star` · `Parameters.smul_eq_self_iff_eq_one` · `Parameters.q_eq_of_modEq_one`

Lemma 6.9 (An integer of norm p times a number prime to p)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number with $p \equiv 1 \bmod N_1(P,\mu)\,d$, w a finite place of $E(P,\mu)$ with $p \in w$, and a an integer of $E(P,\mu)$ such that $a\,\overline{a} = p\,k$ for a natural number k prime to p. Then $\overline{a} \in w$ if and only if $a \notin w$. If $a \in w$, then a has valuation exactly 1 at w.*

Proof. $a\,\overline{a} \in w$, so one of the two lies in w. If both did, then $p\,k \in w^2$ with $k \notin w$, so $p \in w^2$, against Lemma 6.5. The valuations of a and $\overline{a}$ at w add up to that of $p\,k$, which is 1. □

LEAN `Parameters.star_mem_iff` · `Parameters.intValuation_eq_of_mul_star`

Proposition 6.10 (As many places above p and a as infinite places)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number with $p \equiv 1 \bmod N_1(P,\mu)\,d$, and a an integer of $E(P,\mu)$ such that $a\,\overline{a} = p\,k$ for a natural number k prime to p. Then there is a bijection from $\mathrm{Pl}(P,\mu)$ onto the set of finite places of $E(P,\mu)$ that contain both a and p.*

Proof. Fix a finite place w containing p. Send v to $v \cdot w$ if $a \in v \cdot w$ and to $\overline{v \cdot w}$ otherwise. Both places contain p, and exactly one of them contains a (Lemma 6.9), so the map is well defined. If u and v have the same image, then $u \cdot w$ and $v \cdot w = (u^{-1}v) \cdot (u \cdot w)$ are equal or conjugate; Lemma 6.8 excludes the second and turns the first into $u = v$. A place containing a and p is $v \cdot w$ or $\overline{v \cdot w}$ for some v (Lemma 6.6), and then it is the image of v. □

LEAN `Parameters.nonempty_infinitePlace_equiv_finPlace`

7 Weil data

Lemma 7.1. *Let $P = (N_0, d)$ be parameters, μ a natural number, f an injective endomorphism of the ring of integers of $E(P,\mu)$ and w a finite place of $E(P,\mu)$. Then $f(\partial(P,\mu))$ and $\partial(P,\mu)$ have the same valuation at w.*

Proof. $f(\partial(P,\mu))$ is the derivative of the cyclotomic polynomial at the primitive root $f(\varsigma(P,\mu))$, and by Theorem C(a) it generates the same ideal as $\partial(P,\mu)$. □

LEAN `Parameters.valuation_map_relDifferentGen`

Definition 7.2 (The idele of the different)**.** Let $P = (N_0, d)$ be parameters and μ a natural number. $\alpha(P,\mu)$ is the finite idele of $E(P,\mu)$ whose component is $\partial(P,\mu)^{-1}$ at the finite places that contain $c_0(P,\mu)$, and 1 at all others.

LEAN `Parameters.α`

Lemma 7.3. *Let $P = (N_0, d)$ be parameters, μ a natural number and w a finite place of $E(P,\mu)$. Then the inverse of $\alpha(P,\mu)$ and the product $N_1(P,\mu)\cdot\alpha(P,\mu)$ are integral at every finite place, and the component at w of $\alpha(P,\mu)\cdot\overline{\alpha(P,\mu)}\cdot\partial(P,\mu)$ is a unit.*

Proof. The first two assertions hold because $\partial(P,\mu)$ is an integer that divides $N_1(P,\mu)$. For the third, the component of the conjugate idele at w is $\overline{\partial(P,\mu)}^{-1}$ if $\overline{c_0(P,\mu)} = 1 - c_0(P,\mu)$ lies in w, and 1 otherwise. Not both $c_0(P,\mu)$ and $1-c_0(P,\mu)$ lie in w. If exactly one does, the component in question is 1 or $\partial(P,\mu)/\overline{\partial(P,\mu)}$, a unit by Lemma 7.1 for complex conjugation. If neither does, the component is $\partial(P,\mu)$, and $\partial(P,\mu) \notin w$: otherwise $N_1(P,\mu) \in w$, and as $N_1(P,\mu)$ divides a power of $(d+1)/4 = c_0(P,\mu)(1-c_0(P,\mu))$ by Lemma 3.1(b), one of the two factors would lie in w. □

LEAN `Parameters.inv_α_mem` · `Parameters.v_alpha_mul_relDifferentGen` · `Parameters.N₁_mul_α_mem`

Inputs. In (I4) to (I6), F is a CM field with a chosen embedding ι_v at every infinite place v. (I4), unit 106: *Weil data* for F consist of a primitive root of unity of order 5040 in F, a *splitting character* (a continuous unitary character v of the ideles of F, trivial on $F^\times$, with $v(\overline{x}) = v(x)^{-1}$ for every idele x, and with $v(x) = \prod_v x_v/|x_v|$ for every idele x whose finite components are all local units), an element $\jmath \in F$, and a finite idele, such that: $\overline{\jmath} = -\jmath$; the imaginary part of $\iota_v(\jmath)$ is positive for every infinite place v; the product of $\jmath$, the idele and its conjugate generates the inverse of the different over $\mathbb{Z}$ at every finite place; $(1-\jmath^{-1})/2$ is an algebraic integer; and v takes the value -1 at a uniformiser of every finite place w with $\overline{w} = w$. (I5), unit 104: let F contain a primitive root of unity of order 5040 (the formal text calls such a CM field *stably unramified*: then F contains a square root of -1 and $(1+\sqrt{-7})/2$, so it is unramified over its maximal totally real subfield at every finite place). If every root of unity y of F is $y = u/\overline{u}$ for a unit u of the ring of integers with $\prod_v \iota_v(u) = 1$, then F has a splitting character. (I6), unit 97: every splitting character takes the value -1 at a uniformiser of every finite place w with $\overline{w} = w$.

Proposition 7.4 (Weil data for the CM field)**.** *Let $P = (N_0, d)$ be parameters and μ a natural number. The field $E(P,\mu)$, with the embeddings of Definition 4.4, has Weil data in the sense of (I4), with $\jmath = -1/\sqrt{-d}_{P,\mu}$ and the idele $\alpha(P,\mu)$.*

Proof. As $5040 = 2^4 \cdot 3^2 \cdot 5 \cdot 7$ divides $N_1(P,\mu)$ ($2^4 \cdot 5 \cdot 7$ divides 18480, hence N_0, and 3^2 divides 3^5, hence $\mathrm{tw}(\mu)$), a power of $\varsigma(P,\mu)$ has order 5040: this is the first datum of (I4) and the first hypothesis of (I5). For the second hypothesis of (I5), let y be a root of unity; $y = \varsigma(P,\mu)^n$ by Lemma 4.8(a). Put $i = N_1(P,\mu)/4$, a natural number, and

$$u = \varsigma(P,\mu)^i\,(\varsigma(P,\mu) - 1).$$

Its norm to $K(P)$ is 1: the norm of $\varsigma(P,\mu)$ is 1, and the norm of $\varsigma(P,\mu) - 1$ is the value $\Psi_{N_1(P,\mu)}(1)$, by Lemma 4.1 and because the degree is even; that value is 1 since $N_1(P,\mu)$ is not a power of a prime. So u is a unit, and $\prod_v \iota_v(u) = 1$ by Lemma 4.8(b). Further $\overline{u} = \varsigma(P,\mu)^{-i}(\varsigma(P,\mu)^{-1} - 1) = -\varsigma(P,\mu)^{-i-1}(\varsigma(P,\mu) - 1)$, and $\varsigma(P,\mu)^{2i} = -1$, so $\varsigma(P,\mu)\,\overline{u} = u$; hence $y\,\overline{u^n} = u^n$, and (I5) gives a splitting character. Now $\jmath$: its conjugate is $-\jmath$ by Lemma 5.2; $\iota_v(\jmath) = \mathrm{i}/\sqrt{d}$ for every v, because ι_v is the identity on $K(P)$; and $(1 - \jmath^{-1})/2 = c_0(P,\mu)$. By Lemma 7.3 and Theorem C(b), $\jmath\,\alpha(P,\mu)\,\overline{\alpha(P,\mu)}$ has at every finite place the valuation of the inverse of $\partial(P,\mu) \cdot \sqrt{-d}_{P,\mu}$, a generator of the different. The last condition is (I6). □

LEAN `Parameters.instWeilDataE`

8 Notes on the formal text

Names and arguments. The formal text writes N_0 and d as the two components of P, and every other object of this note as a function of P and the exponent; the note keeps all explicit arguments. Three notations show less than the full list of arguments, and say so where they are defined: the Frobenius element and the permutation of places have P as an implicit argument, and the restriction gal_v has both P and μ implicit. The class map takes P and a proof of a divisibility; the note writes the divisibility. The formal text calls the exponent `s` and the root of unity `ζ`; this write-up keeps those letters for the complex variable and for Riemann's function.

Signatures that the reader of the unit derived. For eleven declarations of this note the list of arguments in the dossier is derived from Lean's rule for section variables and not printed by Lean: Theorem B(a), the statements of Lemmas 6.6, 6.9 and Proposition 6.10, the three statements on places in Lemma 6.8, the two equivalences of Lemma 6.7, and Theorem C(a). I read each of them in the Lean text and agree: where the statement binds a variable itself (the place v in Lemma 6.6, the exponent in Theorem B(a) and Lemma 6.7, the element y of Theorem C(a), the cofactor k of Lemma 6.9), the section variable of the same name is not an argument; and the hypothesis $p \in w$ is an argument of the three statements of Lemma 6.8 that mention w, because the text includes it again after having omitted it. This follows the documented rule; only Lean's own output can confirm it, and nothing was compiled here.

The embedding into the cyclotomic field. The census of the workspace records one explicit argument for the embedding of Lemma 4.2, an element of $E(P,\mu)$. In the Lean text the declaration is a homomorphism of $\mathbb{Q}$-algebras with the two implicit arguments P and μ and no explicit one; the arrow of the homomorphism was read as an argument. The note accounts for the entry by naming the field.

Where the formal statements differ from the natural ones. Theorem A(a) is stated in Lean with the class map for the divisor $N_1(P,\mu)$ of itself, which is $\mathrm{cyc}_{P,\mu}$. Lemma 3.1(b) is stated in Lean with the quotient $(d+1)/4$ of natural numbers; it is exact. In Theorem B and Lemmas 6.3, 6.4 the pair $(\mathfrak{c}, e)$ is a ring automorphism and an integer with the hypothesis that they form one of the two pairs; the group $\mathrm{Pl}(P,\mu)\times\mathbb{Z}$ has the integers as a multiplicative monoid, so the order in Theorem B(b) is the order in a monoid. Valuations are multiplicative in Lean: "valuation exactly 1" is there the value, in the value group of the discrete valuation, that Lean writes `.exp (-1)`, the value of a uniformiser (not the real number e^{-1}). The census of the workspace cuts the statement of Theorem C(a) at the word `let`; the statement runs two lines further, as the reader's corrected list of statement spans records and as the Lean file shows, and for this reason it is not among the statements quoted in Appendix A. In Lemma 6.8 the first two assertions do not assume that p is prime; the formal text removes that hypothesis explicitly. Lemma 4.5(c) and (e) hold for all integers ν, by the convention that an integer not prime to the order names the unit place. Proposition 7.4 is an instance: it provides the data rather than asserting their existence, and it depends on the choices of Lemma 5.4 and of (I5). The formal definition behind (I4) lists the root of unity of order 5040 as the property that (I5) assumes, and it writes $\jmath$ as `j`; in the overview of the handout the letter j with its dot is a homomorphism of rings from $\mathbb{C}$ to a non-archimedean field. The first hypothesis of (I5) cannot be dropped. The field $\mathbb{Q}(\sqrt{3},\sqrt{-2})$ has the roots of unity ±1, and $u=(\sqrt{-2}+\sqrt{-6})/2$ is a unit in it with $u/\overline{u}=-1$ and, for the two embeddings that send $\sqrt{-2}$ to the upper half-plane, with $\prod_v \iota_v(u)=1$. But a splitting character of a CM field restricts to the ideles of the maximal totally real subfield as the quadratic character of the extension, and its values on the ideles with unit finite components show that this character is unramified at every finite place; the field $\mathbb{Q}(\sqrt{3},\sqrt{-2})$ is ramified over $\mathbb{Q}(\sqrt{3})$ above 2. (This example is due to the referee of the note and was checked by hand; it is not in the formal text.)

What is used where. Inside the unit, the note *Admissible data* uses Theorem A, Lemmas 3.1 and 4.5, Lemmas 6.5 and 6.9, and Proposition 6.10. The remaining results serve later units: Lemma 4.7 the conjugates of algebraic parts, Lemmas 6.7 and 3.2 the local analysis at the primes that do not split in $K(P)$, Theorem C and Proposition 7.4 the Weil representation. This was seen from the places of use in the source, not from a kernel export.

How this note was written. From the dossier of the unit: the texts of its members and the structured proofs of the declarations of the two files treated here. I read both Lean files completely and compared every statement of this note with the Lean statement, argument by argument, with the lists of arguments of the census and of the dossier. The proofs follow the structured proofs; those of Lemma 3.1(d), Lemma 4.5(c) and Theorem A(c), (d), which the formal text leaves to automation,

are mine. The Inputs were taken from the dossier's reading of the library and from the library's own comments; I opened the definition (I4) and the statements of (I0), (I1′) and (I5), and none of the proofs behind (I0) to (I6). In the revision of 26 November 2026, after a referee's report, the hypothesis of (I5) on the root of unity of order 5040 was restored from the formal statement, and (I0) and (I1′) were moved from the proofs into the box of Inputs. A second reading of the unit by the reading agent arrived while this note was written; its three corrections that touch this note (the polynomial that defines the field, the direction of the automorphism in Lemma 6.6, the value of a uniformiser) were checked against the Lean text and adopted. The program check of the unit's dossier covered 145 leaf steps of 39 proofs.

Appendix A. Concordance with the Lean artifact

The formal names of the objects: `P.N₀`, `P.d` are N_0, d; `towerDeg` applied to μ is $\mathrm{tw}(\mu)$; the exponent `s` is μ; `P.ζ s` and `P.zetaInt s` are the root of unity; `P.Φ s` is the group of places and `Φ v` the embedding ι_v; `star` is complex conjugation. Three statements as the artifact has them:

```
@[local grind] structure Parameters where
  (N₀ d : ℕ)
  dvd_N₀ : 18480 ∣ N₀
  d_prime : d.Prime
  /-- `d ≡ N₀/2 - 1 mod N₀`. -/
  d_congr : N₀ ∣ 2 * (d + 1) ∧ ¬N₀ ∣ d + 1

lemma prod_varpi_eq_rootDiscr_pow : ∏ v : P.Φ s, v (P.ϖ s).val =
  rootDiscr (P.E s) ^ numInfPlaces (P.E s)

lemma smul_eq_iff_exists_frobElem_pow : v • w = comap c c.surjective w ↔ ∃ n, (v, e) =
  P.frobElem s p ^ n
```

Notation

$P = (N_0, d)$ parameters (Definition 2.1)

μ the exponent, a natural number

$\mathrm{tw}(\mu)$, $N_1(P,\mu)$ the tower degree; the order of the root of unity

$M_\omega(P,\mu)$ the number $(N_0 d)^{\mu+6}$

$K(P)$, $\chi_{K(P)}$ $\mathbb{Q}(\sqrt{-d})$ and its quadratic character

$E(P,\mu)$, $\varsigma(P,\mu)$ the CM field and its chosen root of unity

$\mathrm{Pl}(P,\mu)$ the group of infinite places of $E(P,\mu)$

$\Omega(P,\mu)$, $\mathrm{rd}_{E(P,\mu)}$ the period of Definition 2.3; the root discriminant; $\mathrm{cs}(d)$ as there

$\mathrm{gal}_{P,\mu}$, $\mathrm{cyc}_{P,\mu}$ from places to automorphisms and to classes

$[\nu]_{P,\mu}$ the place named by the integer ν

$\mathrm{cl}_P^{m' \mid N_1(P,\mu)}$ the class of a place modulo a divisor m' of $N_1(P,\mu)$

ι_v, ι_1 the chosen embedding at the place v, at the unit place

$\mathrm{perm}_\mu(\sigma)$ the permutation of places by $\sigma \in \mathrm{Aut}(\mathbb{C})$

Ψ_M the cyclotomic polynomial of order M (the letter Ψ is local to this note); X its variable; Q a cofactor

$\mathcal{O}$, $\mathcal{O}_K$, $\mathcal{O}_F$ rings of integers

$c_0(P,\mu)$, $\sqrt{-d}_{P,\mu}$ $(1+\sqrt{-d})/2$ and $\sqrt{-d}$ in $\mathcal{O}$

$\partial(P,\mu)$, $\varpi(P,\mu)$ generators of the different over $K(P)$ and over $\mathbb{Q}$

gal_v the restriction of $\mathrm{gal}_{P,\mu}(v)$ to $\mathcal{O}$

$v \cdot w$, $\overline{w}$ the action of a place v on a finite place w; the conjugate place

$\mathrm{Fr}_\mu(p)$ the Frobenius element at p

$\alpha(P,\mu)$ the idele of Definition 7.2

p a prime number, or a natural number where said

v, v', u, v^* infinite places

w, w' finite places

$\mathfrak{c}, e$ an automorphism of $\mathcal{O}$ and a sign (Setting 6.2)

R, ψ, ψ' a ring; homomorphisms and embeddings (local to this note)

$\chi(p)$ in (I1′): the Legendre symbol of p modulo d

φ, π, L Euler's function; the circle constant; in "L-function"

F, F' auxiliary number fields

x, y, z, a elements of fields and rings

n, i, l, k, o natural numbers and integers: exponents, orders, degrees, a cofactor

ν an integer naming a place

σ, γ an automorphism of $\mathbb{C}$; an element of a Galois group

$\jmath$ the purely imaginary element of the Weil data

υ a splitting character

f an endomorphism of $\mathcal{O}$

u_0, u_x the unit of Lemma 5.4 and its factors

u also a unit, in (I5) and in the proof of Proposition 7.4

Admissible data: scales, ranks and sizes, and their existence

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The whole argument is run on one record of numbers and places, the *admissible data* D: three scales $x(D)$, $x_1(D)$, $b(D)$ with $\log b(D) \ll x(D) \ll x_1(D) \ll b(D)$, the number of lifts $m(D) \approx \sqrt{x(D)}$ and the rank $r(D) \approx x(D)^5$, a set of *thick* infinite places of the CM field $E(D)$ that satisfies no multiplicative relation with small exponents, and two auxiliary primes. This note states the record, names what the later chapters compute from it (ranks, the order $a(D)$, weights, the prime sum, the budget), and describes the device by which the formal text compares sizes: every quantity carries an upper and a lower exponent, and two quantities are compared by their exponents (Theorem B). It then proves that admissible data exist at every large scale (Theorem A), by a weak form of the Siegel–Walfisz theorem, a pigeonhole in the class group and a construction of Behrend type.

What this note is. The artifact grh-compact is a body of Lean code whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. That is a claim: its authors report that Lean's kernel accepts the code; a replay of that check by the owner of this write-up was started, and the handout's record of checks gives its state; nothing was compiled for this note; no mathematician has read the proof through. This note treats the second part of one unit (the folder of the data of the proof): 98 of its 239 declarations, among them nine definitions recalled from the first part, the note *The parameters and the CM field*. Every statement was compared, argument by argument, with the Lean text. Proofs are complete, with two exceptions that are said where they occur: results of other units and of the background library are quoted as *Inputs*, and the comparisons of exponents that the formal text leaves to a decision procedure are carried out here by hand only in the cases listed in Section 7. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 98 declarations.

1 The statements

Theorem A (admissible data exist). Let $P = (N_0, d)$ be parameters and ε a real number with $0 < \varepsilon/6$ and $\varepsilon < 1/100$. Then for every sufficiently large real number y there are admissible data D for P (Definition 2.3) such that

$$x(D) = y, \qquad \log x_1(D) = y^{\varepsilon/6}, \qquad (10^6 \log y)^2 \le \log x_1(D),$$

$$\log\log b(D) = \varepsilon \log y, \qquad \mathrm{tw}(\mu(D))/\log b(D) \le \#\,\mathrm{thick}(D).$$

By Theorem A(d) of the first part, $\mathrm{tw}(\mu(D))$ is the number of the places of class 1 modulo N_0, the set $\mathrm{tops}(D)$. So the last inequality says that the thick places are at least as many as the tops divided by $\log b(D)$.

Theorem B (comparison by exponents). Let D be admissible data for parameters $P = (N_0, d)$, and let l, l' be real numbers with $l < l'$.

(a) If F, G are real numbers with $\mathrm{Bd}_D^{\top}(F; l)$ and $\mathrm{Bd}_D^{\perp}(G; l')$, that is $|F| \le e^{l}$ and $e^{l'} \le G$, then $F < G$, and so $F \le G$.

(b) If A, B are natural numbers with $\mathrm{Bd}_D^{\top}(A; l)$ and $\mathrm{Bd}_D^{\perp}(B; l')$, then $A < B$, and so $A \le B$.

The statement is immediate. What it stands for is a method. In the formal text the two bounds are found mechanically from the shape of the expressions F and G (Proposition 3.4 and Table 1), and the inequality $l < l'$ between two linear expressions in $\log x(D)$, $\log x_1(D)$, $\log b(D)$, $\log\log b(D)$ is found from the conditions on the scales. All comparisons of sizes of the later chapters are made in this way.

2 The setting

Conventions. log is the natural logarithm and e its base; for natural numbers, subtraction stops at 0 and $\lfloor\ \rfloor$ is the floor, as in the formal text. A *finite place* of a number field is a nonzero prime ideal of its ring of integers, written like the ideal, with norm $\mathrm{N}(w)$; an *infinite place* is an archimedean absolute value. The bar is complex conjugation on a CM field and on its finite places. An index set I is a finite set.

Definition 2.1 (Recalled from the first part)**.** *Parameters* are a pair $P = (N_0, d)$ of natural numbers with $18480 \mid N_0$, d prime, $N_0 \mid 2(d+1)$ and $N_0 \nmid d+1$. For a natural number μ: $\mathrm{tw}(\mu) = 3^{\lfloor \log_3 \mu \rfloor + 5} 2^{\mu}$, $N_1(P,\mu) = N_0\ \mathrm{tw}(\mu)$ and $M_\omega(P,\mu) = (N_0 d)^{\mu+6}$; $K(P) = \mathbb{Q}(\sqrt{-d}) \subset \mathbb{C}$, with quadratic character $\chi_{K(P)}$; $E(P,\mu)$ is $K(P)$ with the roots of unity of order $N_1(P,\mu)$ adjoined, a CM field; $\mathrm{Pl}(P,\mu)$ is the set of its infinite places, a commutative group isomorphic to $(\mathbb{Z}/N_1(P,\mu))^{\times}$; for an integer ν, $[\nu]_{P,\mu} \in \mathrm{Pl}(P,\mu)$ is the place whose class is ν if ν is prime to $N_1(P,\mu)$, and the unit element otherwise; for a natural number m' with $m' \mid N_1(P,\mu)$, $\mathrm{cl}_P^{m' \mid N_1(P,\mu)} \colon \mathrm{Pl}(P,\mu) \to (\mathbb{Z}/m')^{\times}$ is the class modulo m'; and $\Omega(P,\mu) = \exp(\mathrm{cs}(d)) \cdot 2\pi/\mathrm{rd}$, with rd the root discriminant of $E(P,\mu)$ and $\mathrm{cs}(d)$ Euler's constant minus the real part of the logarithmic derivative at 1 of the L-function of $\chi_{K(P)}$.

LEAN towerDeg · Parameters.N₁ · Parameters.Mω · Parameters.K · Parameters.E · Parameters.Φ · Parameters.placeOfInt · Parameters.placeClass · Parameters.bigOmega

Definition 2.2 (The constant of the parameters)**.** For parameters $P = (N_0, d)$,

$$C(P) = C_{\mathrm{jet}} + (2d+6) + \Big(N_0 + |\mathrm{cs}(d)| + \sum_{x} \big|\log|\Psi'_{N_0}(x)|\big|\Big),$$

where x runs over the complex primitive roots of unity of order N_0, Ψ_{N_0} is the cyclotomic polynomial of that order, and C_{jet} is a natural number chosen from an existence statement of unit 150 (there it bounds the size of the conjugates of certain

algebraic numbers of the Weil representation; this unit uses nothing about it). What this unit uses of $C(P)$ is Lemma 3.5.

LEAN `Parameters.c`

Definition 2.3 (Admissible data)**.** Let $P = (N_0, d)$ be parameters. *Admissible data for P* are a record D with the following components and properties. Components: three real numbers, the logarithms $\log x(D)$, $\log x_1(D)$, $\log b(D)$ of the scales of Definition 2.4; natural numbers $\mu(D)$, $m(D)$, $r(D)$; a finite set $\mathrm{thick}(D)$ of infinite places of $E(P, \mu(D))$, the *thick places*; natural numbers $g_0(D)$, $g_1(D)$; and an integer $\pi_g(D)$ of $K(P)$. Properties:

(D1) $10^{12}\, C(P) \le \log\log b(D)$, $100 \log\log b(D) \le \log x(D)$, $10^6 \log x(D) \le \log x_1(D)$, $10^6 \log x_1(D) \le \log b(D)$ and $6 \log\log x_1(D) \le \log\log b(D)$.

(D2) $\mu(D) \le 32 \log x(D)$.

(D3) $\sqrt{x(D)} \le m(D) \le 2\sqrt{x(D)}$, and there is a natural number n with $m(D) = 2^{n+1}$ and $\mu(D) = 22(n+1)$.

(D4) $x(D)^5 \le r(D) \le 3\, x(D)^5$, and there is a natural number n with $r(D) = 3^{n+1}$.

(D5) For every natural number m' with $m' \mid N_1(P, \mu(D))$ that divides $N_0 \cdot 3^{\lfloor \log_3 \mu(D) \rfloor + 5}$, every thick place has class -1 modulo m': $\mathrm{cl}_P^{m' \mid N_1(P,\mu(D))}(\tau) = -1$ for all $\tau \in \mathrm{thick}(D)$.

(D6) Let $\psi = \mathrm{cl}_P^{2^{\mu(D)+1} \mid N_1(P,\mu(D))}$ be the class modulo $2^{\mu(D)+1}$. For all natural numbers i, j with $0 < i < j \le 324\, \mu(D)$ and all $\tau, \tau', \tau'' \in \mathrm{thick}(D)$: if $\psi(\tau'/\tau)^j = \psi(\tau''/\tau)^i$, then $\psi(\tau'/\tau) = 1$.

(D7) $g_0(D) \ne g_1(D)$; and for $i \in \{0, 1\}$: $g_i(D)$ is a prime number, $g_i(D) \equiv 1 \bmod N_1(P, \mu(D))\, d$, the square of $M_\omega(P, \mu(D))$ divides $g_i(D) - 1$, and $b(D)^{10} \le g_i(D) \le b(D)^{11}$.

(D8) $\pi_g(D) \cdot \overline{\pi_g(D)} = g_0(D)\, g_1(D)$.

(D9) For every real number y with $100 \log b(D) \le y \le 2^{\mu(D)}$ there is a prime number p with $p \equiv 1$ modulo the square of $M_\omega(P, \mu(D))$ and $y \le \log p \le y + \sqrt{\log b(D)}$.

LEAN `Data`

Definition 2.4 (The scales)**.** For admissible data D for parameters $P = (N_0, d)$, the three *scales* $x(D)$, $x_1(D)$, $b(D)$ are the exponentials of the three real numbers that D stores. In terms of them (D1) reads

$$\exp(10^{12} C(P)) \le \log b(D), \qquad (\log b(D))^{100} \le x(D), \qquad x(D)^{10^6} \le x_1(D),$$
$$x_1(D)^{10^6} \le b(D), \qquad (\log x_1(D))^6 \le \log b(D).$$

LEAN `Data.x` · `Data.x₁` · `Data.b`

Definition 2.5 (The field and its places)**.** Let D be admissible data for parameters $P = (N_0, d)$. Put $N_1(D) = N_1(P, \mu(D))$, $E(D) = E(P, \mu(D))$ and $\mathrm{Pl}(D) = \mathrm{Pl}(P, \mu(D))$; let $f(D)$ be the number of elements of $\mathrm{Pl}(D)$ and $\mathrm{rd}(D)$ the root discriminant of $E(D)$. The formal text also names the product $N_1(D) \cdot d$, the order of a cyclotomic field that contains $E(D)$. For an integer j, $[j]_D = [j]_{P,\mu(D)}$. The *tops* are the places of class 1 modulo N_0,

$$\mathrm{tops}(D) = \{\tau \in \mathrm{Pl}(D) : \mathrm{cl}_P^{N_0 \mid N_1(P,\mu(D))}(\tau) = 1\},$$

and $g(D) = g_0(D)\, g_1(D)$.

Definition 2.6 (Ranks and gaps)**.** Let D be admissible data for parameters $P = (N_0, d)$, and j a natural number. Put

$$k(D) = (r(D) + 1) - m(D), \qquad t(D) = 5\, r(D),$$

$$n_j(D) = k(D) + j\,(t(D) + 1), \qquad \mathrm{pos}_j(D) = k(D) + j - 1,$$

$$h_2(D) = r(D)^8, \qquad h(D) = 2\, h_2(D), \qquad h_2'(D) = h_2(D) - \lfloor (t(D) + 1)/2 \rfloor.$$

LEAN Data.k · Data.t · Data.n · Data.posRank · Data.h₂ · Data.h · Data.reducedHalfGap

Definition 2.7 (The order and the weights)**.** Let D be admissible data for parameters $P = (N_0, d)$, y a real number, j a natural number and $\tau \in \mathrm{Pl}(D)$. $\lceil y \rceil_D$ is the least natural multiple of $N_1(D)$ that is at least y (it is 0 for $y \le 0$). Put

$$a(D) = \lceil x(D)\, b(D) \rceil_D, \qquad b_1(D) = \lceil a(D)/x(D) \rceil_D, \qquad b_2(D) = \lceil a(D)/x_1(D) \rceil_D.$$

The *nominal weight* $w_D(\tau)$ is $a(D)/x(D)$ if $\tau \in \mathrm{thick}(D)$ and $a(D)/x_1(D)$ otherwise. The *weight* $w_{D,j}(\tau)$ is $b_1(D) + j\, h(D) + h_2(D)$ if $\tau \in \mathrm{thick}(D)$ and $b_2(D) + j\, h(D) + h_2(D)$ otherwise.

Definition 2.8 (The prime sum, the budget, the cost of one direction)**.** Let D be admissible data for parameters $P = (N_0, d)$, y a real number, j a natural number and $\tau \in \mathrm{Pl}(D)$. With $\lambda_{d,1}(\nu) = \Lambda(\nu)\,(1 - \chi_{K(P)}(\nu))$, where Λ is von Mangoldt's function (a definition of unit 151), and $(\ )_+$ the positive part,

$$\mathrm{Ask}_D(y, \tau) = \sum_{\nu=1}^{a(D)} \lambda_{d,1}(\nu) \Big(\frac{y}{\nu} - w_D([-\nu]_D \cdot \tau) \Big)_+,$$

$$\mathrm{budget}(D) = f(D)\, a(D)\, (\log b(D))^3, \qquad \mathrm{jet}_D(j) = \log(j!) - j \log \frac{\Omega(P, \mu(D))}{g(D)},$$

$$\mathsf{U}(D) = \sum_{\tau \in \mathrm{Pl}(D)} \Big(\mathrm{jet}_D(w_{D,0}(\tau)) - \mathrm{Ask}_D(w_D(\tau), \tau) \Big).$$

LEAN Data.primeSum · Data.budget · Data.jetSize · Data.dirCost

Why these choices. This paragraph is motivation, taken from the comments of the formal text and from the places where later units use the data; nothing in it is a statement of this unit. The one-sided bound for primes is proved at the scale $x(D)$, and the saving is $1/m(D)$, about $x(D)^{-1/2}$: $m(D)$ is the number of theta lifts. At the much larger scale $x_1(D)$ a second remainder enters, which Chapter II makes harmless by moving $x_1(D)$ inside a window; the conditions leave room for that. The scale $b(D)$ is the size of the weights, which are orders of vanishing: $a(D) \approx x(D)b(D)$ at the tops and about $b(D)$, or $b(D)x(D)/x_1(D)$, at the other places, according to whether the place is thick. All losses of the argument are powers of $\log b(D)$, the unit of the budget, and $(\log b(D))^{100} \le x(D)$ makes them small against the saving. The ranks grow in $2m(D)$ steps of $t(D) + 1$ from $k(D)$; $m(D)$ is a power of 2 and

$r(D)$ a power of 3 so that the parities of Lemma 3.7 hold and $2^{\mu(D)} = m(D)^{22}$ is about $x(D)^{11}$. The thick places all have class -1 modulo N_0, so for a top τ the place $[-\nu]_D \cdot \tau$ can be thick only for $\nu \equiv 1 \bmod N_0$: this is how the progression 1 modulo N_0 enters the prime sum, with the number of thick places as its coefficient, and why Theorem A must provide many of them. Condition (D6) says that the thick places, seen in the 2-part of the group of places, satisfy no relation $\psi(\tau'/\tau)^j = \psi(\tau''/\tau)^i$ with small exponents; a later unit applies it to $\tau' = [-p]_D^i\tau$ and $\tau'' = [-p]_D^j\tau$ for a prime p, so that the powers of one Frobenius class carry a thick place to at most one other thick place. The primes $g_0(D)$, $g_1(D)$ split completely in $E(D)$; they carry an auxiliary level (Section 5), and (D9) is used in unit 141 to choose a prime level $N(D)$ of prescribed size.

3 The calculus of sizes

Definition 3.1 (Bounds on the logarithmic scale)**.** Let D be admissible data for parameters $P = (N_0, d)$, let F and l be real numbers and $*$ one of the two signs $\top$, $\bot$ (a truth value in the formal text). The statement $\mathrm{Bd}^*_D(F;\, l)$ means $|F| \le e^l$ if $* = \top$, and $e^l \le F$ if $* = \bot$. The two cases are also written $\mathrm{Bd}^\top_D(F;\, l)$ for $\mathrm{Bd}^\top_D(F;\, l)$ and $\mathrm{Bd}^\bot_D(F;\, l)$ for $\mathrm{Bd}^\bot_D(F;\, l)$; in the formal text $\mathrm{Bd}^\top_D$ and $\mathrm{Bd}^\bot_D$ are the relation with its sign fixed. The data D do not occur in the meaning: they are an index, which lets the rules below name the quantities of D. We call l an *upper exponent*, respectively a *lower exponent*, of F.

LEAN `Data.HasLogBound` · `Data.HasLogUpper` · `Data.HasLogLower`

Lemma 3.2 (First rules)**.** *Let D be admissible data for parameters $P = (N_0, d)$, let F, G, l, l' be real numbers and A, B natural numbers.*

(a) If $\mathrm{Bd}^\bot_D(F;\, l)$, then $0 < F$.

(b) If $\mathrm{Bd}^\top_D(F;\, l)$ and $|G| \le F$, then $\mathrm{Bd}^\top_D(G;\, l)$. If $\mathrm{Bd}^\top_D(F;\, l)$, $G \le F$ and $0 \le G$, then $\mathrm{Bd}^\top_D(G;\, l)$.

(c) If $\mathrm{Bd}^\top_D(A;\, l)$ and $B \le A$, then $\mathrm{Bd}^\top_D(B;\, l)$.

(d) If $\mathrm{Bd}^\bot_D(G;\, l')$ and $G \le F$, then $\mathrm{Bd}^\bot_D(F;\, l')$.

Proof. Each is a chain of two inequalities, with $e^l > 0$ in (a). □

LEAN `Data.HasLogBound.pos` · `Data.hasLogUpper_of_abs_le` · `Data.hasLogUpper_of_le_of_nonneg` · `Data.hasLogUpper_of_le` · `Data.hasLogLower_of_le`

Lemma 3.3 (The interval rule)**.** *Let D be admissible data for parameters $P = (N_0, d)$, let F, G, H, l, l', l'' be real numbers with $\mathrm{Bd}^\bot_D(G;\, l)$, $\mathrm{Bd}^\top_D(H;\, l')$ and $G \le F \le H$, and let $*$ be one of the two signs. Assume $l' \le l''$ or $l'' \le l$, according to whether $*$ is $\top$ or $\bot$. Then $\mathrm{Bd}^*_D(F;\, l'')$.*

Proof. $0 < e^l \le G \le F \le H \le e^{l'}$, so $|F| \le e^{l'} \le e^{l''}$ in the first case and $e^{l''} \le e^l \le F$ in the second. □

LEAN `Data.HasLogBound.of_mem_Icc`. In the formal text G and H are F by default, and the two last hypotheses are found by automation.

Proof of Theorem B. $F \le |F| \le e^l < e^{l'} \le G$; in (b) the natural numbers are compared as real numbers. □

LEAN Data.lt_of_hasLogBound · Data.le_of_hasLogBound · Data.nat_lt_of_hasLogBound · Data.nat_le_of_hasLogBound

Proposition 3.4 (The rules, and the exponents of the quantities of the data)**.** *Let D be admissible data for parameters $P = (N_0, d)$. Let F, G be real numbers with upper exponents l, l', or with lower exponents l, l'; in the second case they are positive. Then, in the same sense:*

(a) FG has the exponent $l + l'$, and F^A the exponent $A\,l$ for every natural number A;

(b) $F + G$ has the upper exponent $\max(l, l') + 1$, respectively the lower exponent $\max(l, l')$;

(c) $\sqrt{F}$ has the exponent $l/2$; and if F has the lower exponent l and the upper exponent l', then $1/F$ has the upper exponent $-l$ and the lower exponent $-l'$;

(d) a natural number $A \neq 0$ has the upper exponent A and the lower exponent 0, and e^l has both exponents l.

Moreover every line of Table 1 holds: the quantity in the first column has the upper exponent in the second column and, where one is given, the lower exponent in the third.

quantity	upper exponent	lower exponent

$w_{D,0}(\tau)$	$\log b(D) + 2$	that of $w_D(\tau)$, for every $w_{D,j}(\tau)$
$M_\omega(P, \mu(D))$	$\frac{1}{9}\log b(D)$	
$\log \mathrm{ord}_{\mathrm{ch}}(D)$	$32\log x(D)$	

Table 1. Exponents recorded in the formal text; $\tau \in \mathrm{Pl}(D)$, $i \in \{0, 1\}$, j a natural number; $\mathrm{ord}_{\mathrm{ch}}(D)$ is defined in Definition 5.3.

Proof. (a) to (d) are the rules $e^l e^{l'} = e^{l+l'}$, $2 < e$, and $A \leq e^A$. A line of the table follows from the interval rule, Lemma 3.3, applied to the bounds that the definitions give, and from (a) to (d). For example (D3) gives $e^{\log x(D)/2} \leq m(D) \leq 2\,e^{\log x(D)/2}$, and $2 \leq e^2$. For $\mathrm{tw}(\mu(D))$: the factor $2^{\mu(D)} = m(D)^{22}$ has the exponents $11\log x(D) + 44$ and $11\log x(D)$; the factor $3^{\lfloor \log_3 \mu(D) \rfloor}$ is at most $\mu(D) + 1$ and 3^5 has the upper exponent 15, so an upper exponent is $11\log x(D) + \log\log x_1(D) + 60$, which is below the one in the table because $\log\log x_1(D) \leq \frac{1}{6}\log\log b(D)$ and

$\log\log b(D) \geq 10^{12}\, C(P)$ with $C(P) \geq 64$ (Lemma 3.5). The line for $f(D)$ follows from this one by $f(D) = \mathrm{tw}(\mu(D))\,\varphi(N_0)$ (Theorem A(c) of the first part) and $\varphi(N_0) \leq C(P)$. For $a(D)$ use Lemma 3.6: $x(D)b(D) \leq a(D) \leq x(D)b(D) + N_1(D)$. The remaining lines are verified in the same way; we did not redo all of them by hand (Section 7). □

LEAN `Data.hasLogBound_mul` · `Data.hasLogBound_add` · `Data.hasLogBound_natCast` · `Data.hasLogBound_f`; the other rules and lines are instances without names.

The formal text has a few more rules of the same kind, used rarely: for the natural ceiling, the absolute value, a difference, a finite sum, and for upper bounds of logarithms ($\log F$, $\log(FG)$, $\log F^A$, $\log A!$).

Lemma 3.5. *Let $P = (N_0, d)$ be parameters. Then $64 \leq C(P)$, $N_0 \leq C(P)$, $d \leq C(P)$ and $\varphi(N_0) \leq C(P)$, with φ Euler's function.*

Proof. All summands in Definition 2.2 are nonnegative, $64 < d$, and $\varphi(N_0) \leq N_0$. □

LEAN `Data.c_ge`

Lemma 3.6 (Rounding up)**.** *Let D be admissible data for parameters $P = (N_0, d)$, and let F, l be real numbers with $\mathrm{Bd}^{\perp}_D(F; l)$. Then $F \leq \lceil F \rceil_D \leq F + N_1(D)$.*

Proof. $F > 0$, and the least integer $n \geq F/N_1(D)$ satisfies $n < F/N_1(D) + 1$; multiply by $N_1(D)$. □

LEAN `Data.roundUp_mem_Icc`

Lemma 3.7 (Ranks)**.** *Let D be admissible data for parameters $P = (N_0, d)$. Then:*

(a) $r(D)$ is odd, $m(D)$ is even, $k(D)$ is even and $t(D)$ is odd;

(b) $10000 \leq m(D)$; $r(D) + 1 = k(D) + m(D)$; $k(D) \leq r(D)$; $100\, m(D) \leq k(D)$; $0 < k(D)$;

(c) $r(D) + 6 \leq t(D)$; $k(D) + t(D) + 1 \leq h_2(D)$; and $j \mapsto n_j(D)$ is monotone.

Proof. By (D3) and (D4), $m(D)$ is a power of 2 and $r(D)$ a power of 3, both with positive exponent. From Table 1 and Theorem B: $10000 < m(D)$, because $10000 < \frac{1}{2}\log x(D)$ by (D1) and Lemma 3.5; and $2\, m(D) \leq r(D)$, because $\frac{1}{2}\log x(D) + 4 < 5\log x(D)$. So the subtraction in $k(D)$ is exact, $r(D)/2 \leq k(D) \leq r(D)$, and $100\, m(D) \leq k(D)$ because $\frac{1}{2}\log x(D) + 102 < 5\log x(D) - 2$. The parities follow from $k(D) = r(D) + 1 - m(D)$ and $t(D) = 5\, r(D)$. Finally $r(D) \geq 3$ gives $r(D) + 6 \leq 5\, r(D)$ and $k(D) + t(D) + 1 \leq 6\, r(D) + 1 \leq r(D)^8$. □

Lemma 3.8. *Let D be admissible data for parameters $P = (N_0, d)$, and $\tau \in \mathrm{Pl}(D)$ with $\tau \in \mathrm{thick}(D)$. Then $\mathrm{cl}_P^{N_0 | N_1(P, \mu(D))}(\tau) = -1$.*

Proof. This is (D5) for the divisor N_0. □

LEAN `Data.placeClass_of_thick`

4 Weights

Lemma 4.1 (Nominal weights and weights)**.** *Let D be admissible data for parameters $P = (N_0, d)$, $\tau \in \mathrm{Pl}(D)$ and j a natural number. Then*

(a) $a(D)/x_1(D) \le w_D(\tau) \le a(D)/x(D)$*; in particular* $0 \le w_D(\tau)$*;*

(b) $w_D(\tau) + x(D)^{42} \le 2\,b(D)$*;*

(c) $w_D(\tau) \le w_{D,j}(\tau) - h_2(D)$*;*

(d) if $j \le 2\,m(D)$*, then* $w_{D,j}(\tau) \le w_D(\tau) + x(D)^{42}$*, hence* $w_{D,j}(\tau) \le 2\,b(D)$*, and* $\log w_{D,j}(\tau) \le \log w_D(\tau) + 1/x(D)$*.*

Proof. (a) $x(D) \le x_1(D)$. (b) By (a) and Lemma 3.6, $w_D(\tau) \le (x(D)b(D) + N_1(D))/x(D) = b(D) + N_1(D)/x(D)$, and $N_1(D)/x(D) + x(D)^{42} \le b(D)$ by Theorem B: an upper exponent of the left side is $42\log x(D) + 1$. (c) $b_1(D) \ge a(D)/x(D)$ and $b_2(D) \ge a(D)/x_1(D)$ by Lemma 3.6. (d) By the same lemma the difference $w_{D,j}(\tau) - w_D(\tau)$ is at most $N_1(D) + 2\,m(D)\,h(D) + h_2(D)$, with upper exponent $40.5\log x(D) + 33$, below $42\log x(D)$. With (b) this gives the second inequality. For the third, $w_D(\tau)\,e^{1/x(D)} \ge w_D(\tau) + w_D(\tau)/x(D)$, and $x(D)^{42} \le w_D(\tau)/x(D)$ by Theorem B, since $42\log x(D) < \log b(D) - \log x_1(D) - \log x(D)$. □

5 Chosen places and neat levels

Inputs. Let D be admissible data for parameters $P = (N_0, d)$, and I an index set. (J1), unit 141: a finite place w of $E(D)$ *is chosen* if it contains $\overline{\pi_g(D)}$; for $i \in \{0, 1\}$, $\mathrm{Ch}_i(D)$ is the set of chosen places that contain $g_i(D)$, and every chosen place lies in one of the two. A place containing $g_i(D)$ has norm $g_i(D)$, and $\pi_g(D)\,\overline{\pi_g(D)}$ is $g_i(D)$ times a number prime to $g_i(D)$. (J2), unit 141: the *level* $N(D)$ is a prime number with $N(D) \equiv 1 \bmod N_1(D)\,d$, and $\pi_N(D)$ is an integer of $E(D)$ with $\pi_N(D)\,\overline{\pi_N(D)} = N(D)$. (J3), unit 141: ω_D attaches to every finite place w of $E(D)$ a character $\omega_D(w)$ of its residue field, of order exactly $M_\omega(P, \mu(D))$ if w is chosen, and trivial otherwise. (J4), unit 122: $G_{\mathrm{f}}(D, I)$ is the unitary group of the standard hermitian form with index set I over the finite adeles of $E(D)$, $K_0(D, I)$ its subgroup of matrices that are integral with their inverses, $\Gamma(D, I)$ the image of the unitary group over $E(D)$; for an integer a of $E(D)$ the principal level of a consists of the elements of $K_0(D, I)$ congruent to 1 modulo a. The general linear group with index set I over a finite ring with n elements has at most $n^{(\#I)^2}$ elements. (J5), unit 50, a lemma of Minkowski and Serre: if finitely many distinct finite places of a CM field with more than one infinite place have norms whose product exceeds $2\,\#I$ raised to the degree of the field over $\mathbb{Q}$, then for every subgroup $\mathcal{K}$ of the group of elements of the integral subgroup that reduce to 1 at these places, and every element x of the adelic group, the intersection of the rational group with $x\mathcal{K}x^{-1}$ is trivial. The catalogue of the write-up refers for (J5) to Serre [3] and to Minkowski, as a special case, with the place not confirmed.

Lemma 5.1 (The chosen places)**.** *Let D be admissible data for parameters $P = (N_0, d)$, $i \in \{0,1\}$, and w a finite place of $E(D)$.*

(a) There is a bijection from $\mathrm{Pl}(D)$ onto $\mathrm{Ch}_i(D)$ (the formal text fixes one); so $\mathrm{Ch}_i(D)$ has $f(D)$ elements, and the product of the norms of all chosen places is $g(D)^{f(D)}$.

(b) If $g_i(D) \in w$, then $\overline{w}$ is chosen if and only if w is not. If w is chosen, then $\overline{w}$ is not chosen.

(c) The family of all chosen places, indexed by the pairs of an index i and an element of $\mathrm{Ch}_i(D)$, has as its range the set of chosen places; it is injective, and no member is the conjugate of a member.

Proof. (a) Proposition 6.10 of the first part, for the prime $g_i(D)$, which is $\equiv 1$ mod $N_1(D)\,d$ by (D7), and the integer $\overline{\pi_g(D)}$, with (J1); the places of $\mathrm{Ch}_i(D)$ have norm $g_i(D)$. (b) Lemma 6.9 of the first part, for the same prime and integer; a chosen place contains $g_0(D)$ or $g_1(D)$. (c) Places above $g_0(D) \neq g_1(D)$ have different norms, and (b). □

LEAN `Data.chosenEquiv` · `Data.card_chosenPlace` · `Data.prod_q_chosenPlace` · `Data.isChosen_star_iff` · `Data.IsChosen.not_star` · `Data.range_chosen` · `Data.isConjApart_chosen`

Lemma 5.2 (The level is unramified)**.** *Let D be admissible data for parameters $P = (N_0, d)$ and w a finite place of $E(D)$. If $N(D) \in w$, then $N(D)$ has valuation exactly 1 at w. If $\pi_N(D) \in w$, then $\pi_N(D)$ has valuation exactly 1 at w.*

Proof. Lemmas 6.5 and 6.9 of the first part, for the prime $N(D)$ of (J2), which does not divide $N_1(D)\,d$ because it is $\equiv 1$ mod $N_1(D)\,d$, and for the integer $\pi_N(D)$, whose norm is $N(D)$ times 1. □

LEAN `Data.v_N_eq_exp_neg_one` · `Data.intValuation_pi`

Definition 5.3 (The order and the level of the chosen places)**.** Let D be admissible data for parameters $P = (N_0, d)$. $\mathrm{ord}_{\mathrm{ch}}(D)$ is the order of the product, over all chosen places, of the general linear groups of rank $r(D)\,t(D)$ over the residue fields. For an index set I, which is finite, $K_{\mathrm{ch}}(D, I)$ is the subgroup of the elements of $K_0(D, I)$ that reduce to 1 at every chosen place.

LEAN `Data.chosenGroupOrder` · `Data.chosenLevel`

Lemma 5.4. *Let D be admissible data for parameters $P = (N_0, d)$, and fix a finite index set I. If I has at most $r(D)\,t(D)$ elements, then the order of the product, over all chosen places, of the general linear groups with index set I over the residue fields divides $\mathrm{ord}_{\mathrm{ch}}(D)$. If a is an integer of $E(D)$ divisible by $\overline{\pi_g(D)}$, then the principal level of a is contained in $K_{\mathrm{ch}}(D, I)$.*

Proof. Embed I into a set with $r(D)\,t(D)$ elements and extend matrices by the identity: this is an injective homomorphism of groups, and the order of a subgroup divides the order of the group. Every chosen place contains $\overline{\pi_g(D)}$, hence a. □

LEAN `Data.card_GL_dvd_chosenGroupOrder` · `Data.principalLevel_le_chosenLevel`

Proposition 5.5 (Neat levels, and Minkowski's bound)**.** *Let D be admissible data for parameters $P = (N_0, d)$; fix a finite index set I with at most $2\,n_{m(D)}(D)$ elements and a subgroup $\mathcal{K}$ of $G_{\mathrm{f}}(D, I)$.*

(a) *If $\mathcal{K}$ is contained in $K_{\mathrm{ch}}(D,I)$, then $\Gamma(D,I)\cap x\mathcal{K}x^{-1}$ is trivial for every element x of $G_{\mathrm{f}}(D,I)$.*

(b) *If $\mathcal{K}$ is contained in $K_0(D,I)$, then the order of $\Gamma(D,I)\cap x\mathcal{K}x^{-1}$ divides $\mathrm{ord}_{\mathrm{ch}}(D)$ for every element x of $G_{\mathrm{f}}(D,I)$.*

Proof. (a) is (J5) for the family of chosen places, which is injective (Lemma 5.1). Its hypotheses: $E(D)$ is a CM field with $f(D)=\mathrm{tw}(\mu(D))\,\varphi(N_0)>1$ infinite places (Theorem A(c) of the first part), its degree is $2f(D)$, and the product of the norms is $g(D)^{f(D)}$, so it suffices that $(4\,n_{m(D)}(D))^2<g(D)$, which holds by Theorem B and Table 1: $11\log x(D)+32<20\log b(D)$. (b) Conjugation by x^{-1} followed by reduction at the chosen places is a homomorphism from $\Gamma(D,I)\cap x\mathcal{K}x^{-1}$ to the product of the general linear groups over the residue fields. Its kernel lies in $\Gamma(D,I)\cap x\,K_{\mathrm{ch}}(D,I)\,x^{-1}$, which is trivial by (a). So the order divides that of the product, which divides $\mathrm{ord}_{\mathrm{ch}}(D)$ by Lemma 5.4, since $2\,n_{m(D)}(D)\le r(D)\,t(D)$ by Theorem B: the upper exponent $5.5\,\log x(D)+14$ of $2\,n_{m(D)}(D)$ is below the lower exponent $10\log x(D)$ of $r(D)\,t(D)$. □

LEAN `Data.classAut_eq_bot_of_le_chosenLevel` · `Data.card_classAut_dvd_chosenGroupOrder`

Lemma 5.6 (Powers of the residue characters)**.** *Let D be admissible data for parameters $P=(N_0,d)$ and w a finite place of $E(D)$, and fix an integer ν with $0<|\nu|\le 8\,m(D)$. Then $\omega_D(w)^\nu\neq 1$ if and only if w is chosen.*

Proof. At a place that is not chosen the character is trivial. At a chosen place its order $M_\omega(P,\mu(D))$ is a multiple of $N_1(D)\,d$ (Lemma 3.1(d) of the first part), and $8\,m(D)<N_1(D)\,d$ by Theorem B: $8\,m(D)$ has the upper exponent $\frac12\log x(D)+10$, the number $N_1(D)\,d\ge\mathrm{tw}(\mu(D))$ has the lower exponent $11\log x(D)$, and $\frac12\log x(D)+10<11\log x(D)$. So the order does not divide ν. □

LEAN `Data.omega_zpow_ne_one`. Two instances without names follow in the formal text: the last two lines of Table 1.

For the line of $\log\mathrm{ord}_{\mathrm{ch}}(D)$ in Table 1: by (J4) and Lemma 5.1(a),

$$\mathrm{ord}_{\mathrm{ch}}(D)\le g(D)^{\,f(D)\,(r(D)\,t(D))^2},$$

and the exponent times $\log g(D)$ has an upper exponent below $32\log x(D)$.

6 Existence of admissible data

Proposition 6.1 (A construction of Behrend type)**.** *Let Γ_1, Γ_2 be commutative groups, $\psi\colon\Gamma_1\to\Gamma_2$ a homomorphism, $\tau_0,\gamma\in\Gamma_1$, and n, M, L natural numbers with $L>0$ and $(LM)^n\le o$, where o is the order of $\psi(\gamma)$ (it is 0 in the formal text if that order is infinite). Then there is a finite subset $T\subseteq\Gamma_1$ such that*

(i) *every element of T is $\tau_0\gamma^{\,i}$ for a natural number i;*

(ii) *$M^n/(n\,M^2)\le\#T$;*

(iii) *for all natural numbers i, j with $0<i<j\le L$ and all $\tau,\tau',\tau''\in T$: if $\psi(\tau'/\tau)^j=\psi(\tau''/\tau)^i$, then $\psi(\tau'/\tau)=1$.*

Proof. Among the M^n vectors $u=(u_1,\dots,u_n)$ with integer coordinates $0\le u_k<M$, the sum of squares takes at most $n(M-1)^2+1\le nM^2$ values (for $n,M\ge1$; for $n=0$ or $M=0$ the bound (ii) is 0, Section 7); so for some value q the sphere S of the

vectors with $\sum_k u_k^2 = q$ has at least $M^n/(nM^2)$ elements (this count is in Mathlib). For a vector u with natural coordinates put $[u] = \sum_k u_k (LM)^{k-1}$; the map $u \mapsto [u]$ is additive, and on the vectors with all coordinates below LM it is injective with values below $(LM)^n \le o$. Hence $u \mapsto \psi(\gamma)^{[u]}$ is injective on these vectors. Let T be the set of the $\tau_0 \gamma^{[u]}$, $u \in S$. Then (i) holds, and (ii) because $L \ge 1$ makes the coordinates of S smaller than LM. For (iii) let τ, τ', τ'' come from $u, v, z \in S$ and write $j = i + i'$ with $i' > 0$. The hypothesis says $\psi(\gamma)^{(i+i')[v]} = \psi(\gamma)^{i[z]+i'[u]}$, and both exponents are values of the bracket at vectors with coordinates at most $(i + i')(M - 1) < LM$. So $(i + i')\, v = i\, z + i'\, u$: the point v lies between z and u on a segment, and all three lie on one sphere. Expanding $i^2 z_k^2 = ((i + i')v_k - i' u_k)^2$ and summing,

$$\begin{aligned} i\,(i\,q + i'q) &= \sum_k i\,(i\,z_k^2 + i' u_k^2) = \sum_k (i + i')(i'(u_k - v_k)^2 + i\,v_k^2) \\ &= (i + i')\, i' \sum_k (u_k - v_k)^2 + (i + i')\, i\, q, \end{aligned}$$

so $u = v$, hence $\tau' = \tau$. □

LEAN `exists_three_term_free`. The header of the Lean file cites Shapira [4], Theorem 1, after Behrend [1]; the artifact records these citations as found, with no place compared.

Lemma 6.2 (Pigeonhole in the class group)**.** *Fix a number field F with class number n, and let $\mathfrak{p}_i$, $\mathfrak{q}_i$, for $i \in \{0, \dots, n\}$, be finite places of F such that $\mathfrak{p}_i\mathfrak{q}_i$ is principal for every i. Then there are indices $i \ne j$ such that $\mathfrak{p}_i\mathfrak{q}_j$ is principal.*

Proof. Two of the $n + 1$ classes of the $\mathfrak{p}_i$ are equal, say those of $\mathfrak{p}_i$ and $\mathfrak{p}_j$ with $i \ne j$; then the class of $\mathfrak{p}_i\mathfrak{q}_j$ is that of $\mathfrak{p}_j\mathfrak{q}_j$, the trivial one. □

LEAN `exists_mul_principal`

Inputs. (J6), unit 126, a weak form of the Siegel–Walfisz theorem: let $M > 0$ be a multiple of 4 and A a natural number. For all sufficiently large real W, every natural number $k > 1$ with $M^k \le W^A$ and every real y with $W \le y \le W^A$, there is a prime number $p \equiv 1 \bmod M^k$ with $y \le \log p \le y + W$. This is a weaker consequence of the Siegel–Walfisz theorem, in the form of Montgomery and Vaughan [2], §11.3, Corollary 11.19 (p. 381, for the sum of von Mangoldt's function over a residue class) and Corollary 11.21 (p. 382, for the primes of a residue class): for a modulus that is at most a fixed power of the logarithm of the bound, the primes of a residue class prime to the modulus are counted with an error that saves more than every power of that logarithm. Applied to the primes between e^y and $2e^y$ and to the modulus $M^k \le W^A \le y^A$, this gives, once W is large in terms of M and A, a prime $p \equiv 1 \bmod M^k$ with $y < \log p \le y + \log 2 \le y + W$; for $A = 0$ no y is in the range once $W > 1$. The two places were located and the deduction was made by the reading agent; the book was not opened for this note. The formal proof goes another way: it starts from a small disc around 1 without zeros of the L-functions of the characters modulo M^k. (J7), unit 106: for a prime $d \equiv 7 \bmod 8$ and a prime number p whose Legendre symbol modulo d is 1, the ideal (p) of $\mathbb{Q}(\sqrt{-d})$ is a product of two prime ideals of norm p; and the absolute norm of a principal ideal (y) is $y\,\overline{y}$. (J8), unit 106: if q is an integer with $|q| > 1$ and $q^o \equiv 1 \bmod 2^{\mu+1}$ for a natural number $o > 0$, then $2^\mu \le (|q| + 1)\, o$.

Proof of Theorem A. Write $Y = \log y$ and $W = y^{\varepsilon/6} = e^{\varepsilon Y/6}$, and let $\#\,\mathrm{Cl}(K(P))$ be the class number of $K(P)$. Fix a natural number n with $n > 6$ and $n\,\varepsilon/6 > 99\,N_0 d$. Since W exceeds every fixed multiple of every fixed power of Y when y is large, we may assume all of the following: $Y \geq 2$;

$$W \geq 10^{12}\,Y^2, \qquad W \geq (8019N_0 + 2)\,10368^{\,n}\,Y^{n+1}, \qquad W \geq 8019 \cdot 2^n\,n\,Y,$$

$$W \geq 2\,\#\,\mathrm{Cl}(K(P)) + 10^6, \qquad W \geq \exp(10^{12}\,C(P));$$

and the conclusion of (J6) for the modulus $N_0 d$ and $A = n$ at this W.

Ranks and scales. Choose natural numbers i_2, i_3 with $2^{i_2} \leq e^{Y/2} < 2^{i_2+1}$ and $3^{i_3} \leq e^{5Y} < 3^{i_3+1}$, and put

$$m = 2^{i_2+1}, \qquad r = 3^{i_3+1}, \qquad \mu = 22\,(i_2 + 1),$$

and take Y, W, W^6 for the logarithms of the three scales. Then (D3) and (D4) hold, and $2^\mu = m^{22}$. As $i_2 \log 2 \leq Y/2$ and $Y \geq 2$, we get $\mu \leq 16\,Y + 22 \leq 32\,Y$, which is (D2). For (D1): log log of the third scale is $\log W^6 = \varepsilon Y$, which is at least $10^{12}\,C(P)$ by the last assumption and at most $Y/100$; $10^6 Y \leq W$ and $10^6 W \leq W^6$ hold as $W \geq 10^{12} Y^2$ and $W \geq 10^6$; and $6 \log W = \varepsilon Y$. The same computations give the first four assertions of the theorem.

Primes. First $(N_0 d)^{2(\mu+6)} \leq W^n$: the logarithm of the left side is at most $2(32Y + 6)\,N_0 d \leq 99\,N_0 d\,Y < n \log W$. Hence also $2^\mu \leq W^n$. By (J6) with $k = 2(\mu + 6)$: for every real y' with $W \leq y' \leq W^n$ there is a prime $p \equiv 1$ modulo the square of $M_\omega(P, \mu)$ with $y' \leq \log p \leq y' + W$. This gives (D9), because $W \leq 100\,W^6$, $2^\mu \leq W^n$ and $W \leq \sqrt{W^6}$. For $i \in \{0, \dots, \#\,\mathrm{Cl}(K(P))\}$ apply it to $y' = 10W^6 + 2iW$, which is at most $W^7 \leq W^n$: there are primes $p_i \equiv 1$ modulo the square of $M_\omega(P, \mu)$ with $10W^6 + 2iW \leq \log p_i \leq 10W^6 + (2i + 1)W$. They increase strictly with i, and $10W^6 \leq \log p_i \leq 11W^6$ because $(2\,\#\,\mathrm{Cl}(K(P)) + 1)W \leq W^2$. As $N_1(P, \mu)\,d$ divides $M_\omega(P, \mu)$, each p_i is $\equiv 1 \bmod N_1(P, \mu)\,d$; so its Legendre symbol modulo d is 1 and $(p_i) = \mathfrak{p}_i \mathfrak{q}_i$ in $K(P)$ with prime ideals of norm p_i by (J7). By Lemma 6.2 there are $i \neq j$ and an integer π of $K(P)$ with $\mathfrak{p}_i \mathfrak{q}_j = (\pi)$, so that $\pi\overline{\pi} = p_i p_j$. With the two primes p_i, p_j and the integer π, (D7) and (D8) hold.

Thick places. Put $M_3 = N_0 \cdot 3^{\lfloor \log_3 \mu \rfloor + 5}$, so that $N_1(P, \mu) = M_3\,2^\mu$, and let ψ be the class modulo $2^{\mu+1}$ on $\mathrm{Pl}(P, \mu)$. The integers -1 and $M_3 + 1$ are prime to N_0; put $\tau_0 = [-1]_{P,\mu}$ and $\gamma = [M_3 + 1]_{P,\mu}$. By Lemma 4.5(d) of the first part, $\psi(\gamma)$ is the class of $M_3 + 1$, so its order o satisfies $2^\mu \leq (M_3 + 2)\,o$ by (J8). Choose a natural number i_0 with $2^{n\,i_0} \leq 2^\mu / W < 2^{n(i_0+1)}$; this is possible because $W \leq e^{Y/2} < m \leq 2^\mu$. Now $M_3 \leq 243\,N_0(\mu + 1) \leq 8019\,N_0 Y$ and $324\mu \leq 10368\,Y$, so

$$(M_3 + 2)\,(324\mu \cdot 2^{i_0})^n \leq (8019N_0 + 2)\,10368^{\,n}\,Y^{n+1} \cdot \frac{2^\mu}{W} \leq 2^\mu \leq (M_3 + 2)\,o.$$

Thus Proposition 6.1 applies with $L = 324\mu$ and the side 2^{i_0} in the role of its M. It gives a set T of places with (D6), with at least $2^{n\,i_0}/(n\,2^{2i_0})$ elements, all of the form $[-1]_{P,\mu} \cdot [M_3 + 1]^i_{P,\mu}$. For a divisor m' of M_3, such a place has class $-(M_3 + 1)^i = -1$ modulo m', again by Lemma 4.5(d) of the first part: this is (D5). So the record with thick set T is admissible.

Many thick places. It remains that $\mathrm{tw}(\mu)/W^6 \leq 2^{n\,i_0}/(n\,2^{2i_0})$. Here $\mathrm{tw}(\mu) \leq 243(\mu + 1)2^\mu \leq 8019\,Y \cdot 2^{n(i_0+1)}\,W$, and $2^{i_0} < W$ because $2^{n\,i_0} \leq 2^\mu / W < W^n$. So

$$\frac{\mathrm{tw}(\mu)}{W^6} \cdot \frac{n\,2^{2i_0}}{2^{n\,i_0}} \leq \frac{8019\,Y 2^n\,n\,W^3}{W^6} \leq \frac{W^4}{W^6} \leq 1. \qquad \square$$

7 Notes on the formal text

Names and arguments. In the formal text the scales, the ranks $k(D)$, $t(D)$, the field and every other object of Definitions 2.4 to 2.8 are functions of the data, and the note writes them so. The components of the record are written in the same way, $m(D)$, $r(D)$, $\mu(D)$, $\mathrm{thick}(D)$, $g_i(D)$, $\pi_g(D)$; the overview of the write-up writes some of them without the argument. The record stores the logarithms of the scales, and the scales are their exponentials: the note writes $\log x(D)$ for the stored number. The component that the formal text calls `s` is $\mu(D)$ here. In Lean the hypotheses $\mathrm{Bd}_D^{\top}(F;\, l)$ and $\mathrm{Bd}_D^{\perp}(G;\, l')$ of Theorem B and of Lemmas 3.2 to 3.6 are instance arguments: Lean finds them by search, from the rules of Proposition 3.4 and the lines of Table 1, each of which is an instance; and the hypothesis $l < l'$ of Theorem B has a default proof by a decision procedure.

What was not redone by hand. The formal text proves each line of Table 1, and each use of Theorem B, by one call of a decision procedure on the conditions (D1). In this note the inequalities between exponents are written out for the lines of $m(D)$, $\mathrm{tw}(\mu(D))$, $f(D)$ and for the uses in Lemmas 3.7, 4.1, 5.6 and Proposition 5.5; the other lines of the table are stated as the formal text has them. The exponents given in the proofs are mine and may differ from those that Lean finds. The proof of Theorem A is complete here; the formal proof closes several of its numerical steps by automation, and which goal each tactic settles there was inferred by the reader of the unit from the order of the conditions, not from Lean's output.

Signatures that could not be settled without Lean. (1) For five declarations treated here the list of arguments is derived by the reader of the unit and not printed by Lean: Lemma 3.5, the range and the conjugation statement of Lemma 5.1(c), and the lines of $f(D)$ and of $C(P)$ in Table 1. I read them in the Lean text and agree: the letter that looks like a section variable is in each case another object (the constant of the parameters, written with a dot after P; a variable bound inside the statement). (2) The two lines of Table 1 for $w_{D,0}(\tau)$ and $w_{D,j}(\tau)$ are instances that stand, in the Lean file, after a command that includes the hypothesis $j \le 2\,m(D)$ in what follows. Lean's documentation says that this command concerns theorems and no other declarations; and the proof of Lemma 4.1(d) needs the second instance to be found by search, which could not supply such a hypothesis. So I read both instances without the hypothesis, and the first one without j, against the census of the workspace; only Lean can settle it. (3) The rule for quotients is an instance that takes bounds for F and for $1/G$. The census lists a further bound for G as a possible argument; by Lean's rule for definitions, which keeps a section variable only if the term uses it, it is not one. This too is a reading of the rule, not Lean's answer.

Where the formal statements differ from the natural ones. (D5) quantifies over a number and a proof that it divides the order of the root of unity; the formal text calls this number `m`, a name that hides the component $m(D)$ there, and the note writes m'. The subtraction in $k(D)$, $\mathrm{pos}_j(D)$ and $h_2'(D)$ is that of natural numbers;

Lemma 3.7 shows that it is exact for $k(D)$. In (D7) the formal text says that the pair of primes is injective and that the square of $M_\omega(P, \mu(D))$ divides $g_i(D) - 1$ in natural numbers. In Theorem A the hypothesis is $0 < \varepsilon/6$, and "for every sufficiently large y" is a statement along the filter at infinity. In Proposition 6.1 the bound (ii) is a real quotient, which Lean reads as 0 when $n = 0$ or $M = 0$, and the order of an element of infinite order is 0; then the hypothesis forces $M = 0$ and the statement is empty. Lemma 3.2(a) is all that the formal text uses of positivity. The definition of $h_2'(D)$ and of $\mathrm{pos}_j(D)$ are not used in this unit.

How this note was written. From the dossier of the unit: the texts of its members and the structured proofs of the five files treated here, of which the longest is the proof of Theorem A. I read the five Lean files completely and compared every statement of this note with the Lean statement, argument by argument. The proof of Theorem A follows the formal one step by step, with its constants; the proofs of Lemmas 3.7 and 4.1 and of Proposition 3.4 replace calls of automation by explicit exponents. Of the Inputs I opened only the comments of the formal text and the reading of the dossier, not the proofs. The references are those of the catalogue of the write-up and of the artifact's own list; I did not open the cited works. For (J6) the places in the book and the deduction are those of the reading agent's second reading of the catalogue. In the revision of 26 November 2026, after a referee's report, the infinite places received the letter τ of the overview of the handout, the hypotheses of (J5) and the exponents in Proposition 5.5 and Lemma 5.6 were written out, and (J6) received its deduction. A second reading of the unit by the reading agent arrived while this note was written; I compared its remarks on this part with the Lean text, and they agree with what is stated here. The program check of the unit's dossier covered 145 leaf steps of 39 proofs.

Appendix A. Concordance with the Lean artifact

The formal names of the objects: `D.logX`, `D.logX₁`, `D.logB` are $\log x(D)$, $\log x_1(D)$, $\log b(D)$; `D.s`, `D.m`, `D.r` are $\mu(D)$, $m(D)$, $r(D)$; `D.g i` is $g_i(D)$ and `D.piG` is $\pi_g(D)$; `D.Φ` is $\mathrm{Pl}(D)$; `P.c` is $C(P)$; `primeSum` is the prime sum, `dirCost` the cost of one direction. Three statements as the artifact has them:

Notation

$P = (N_0, d)$ parameters
D admissible data for P (Definition 2.3)
$x(D)$, $x_1(D)$, $b(D)$ the three scales
$\mu(D)$, $m(D)$, $r(D)$ the exponent, the number of lifts, the rank of the rows
$\mathrm{thick}(D)$ the set of thick places
$g_i(D)$, $g(D)$, $\pi_g(D)$ the two auxiliary primes, their product, an integer of that norm
$C(P)$, C_{jet} the constant of the parameters and one of its summands
$\mathrm{tw}(\mu)$, $N_1(P,\mu)$, $M_\omega(P,\mu)$ as in the first part
$K(P)$, $\chi_{K(P)}$, $E(P,\mu)$, $\mathrm{Pl}(P,\mu)$ as in the first part
$[\nu]_{P,\mu}$, $\mathrm{cl}_P^{m'|N_1(P,\mu)}$ the place named by ν; the class modulo a divisor m'
$\Omega(P,\mu)$ the period
$N_1(D)$, $E(D)$, $\mathrm{Pl}(D)$ order, field and places for the exponent of D
$f(D)$, $\mathrm{rd}(D)$ the number of infinite places; the root discriminant
$[j]_D$, $\mathrm{tops}(D)$ the place named by j; the tops
$k(D)$, $t(D)$, $n_j(D)$, $\mathrm{pos}_j(D)$ ranks
$h_2(D)$, $h(D)$, $h_2'(D)$ the half-gap, the gap, the reduced half-gap
$\lceil y \rceil_D$ y rounded up to a multiple of $N_1(D)$
$a(D)$, $b_1(D)$, $b_2(D)$ the order and the two rounded quotients
$w_D(\tau)$, $w_{D,j}(\tau)$ nominal weight; weight
$\mathrm{Ask}_D(y,\tau)$, $\lambda_{d,1}$, Λ the prime sum; its coefficients; von Mangoldt's function
$\mathrm{budget}(D)$, $\mathrm{jet}_D(j)$, $\mathsf{U}(D)$ budget; jet size; cost of one direction
$\mathrm{Bd}^*_D(F;l)$, $\mathrm{Bd}^\top_D$, $\mathrm{Bd}^\bot_D$ bounds on the logarithmic scale; $* \in \{\top, \bot\}$
$N(D)$, $\pi_N(D)$ the level and an integer of that norm
$\mathrm{Ch}_i(D)$, ω_D chosen places above $g_i(D)$; residue characters
$G_{\mathrm{f}}(D,I)$, $K_0(D,I)$, $\Gamma(D,I)$, $K_{\mathrm{ch}}(D,I)$ adelic unitary group, integral subgroup, rational points, level of the chosen places
$\mathrm{ord}_{\mathrm{ch}}(D)$ the order of Definition 5.3
$\#\,\mathrm{Cl}(K(P))$ the class number of $K(P)$
F, G, H real numbers; F also a number field in Lemma 6.2
l, l', l'' exponents
A, B natural numbers; A also the exponent in (J6)
y, y' real numbers; y the scale in Theorem A
Y, W $\log y$ and $y^{\varepsilon/6}$ in the proof of Theorem A
ε the exponent of Theorem A
τ, τ', τ'' infinite places, or elements of the set T
ν an integer
i, j, k, n, o, q natural numbers and integers: indices, exponents, orders
i', i_0, i_2, i_3 exponents in two proofs
m, r, μ in the proof of Theorem A, the components under construction
m' a divisor of the order of the root of unity ((D5), Definition 2.1, proof of Theorem A)
p, p_i prime numbers
M, L a side and a bound (Proposition 6.1); M also the modulus of (J6)
M_3 in the proof of Theorem A: N_0 times the power of 3 in the order of the root of unity
$\Gamma_1, \Gamma_2, \psi, \tau_0, \gamma$ groups, a homomorphism, two elements; ψ also a class map; τ_0 also the place named by -1
T, S a finite set of group elements; a sphere of integer vectors
u, v, z, $[u]$ integer vectors and the bracket of the proof of Proposition 6.1
$\mathfrak{p}_i, \mathfrak{q}_i$, π prime ideals; a generator
w, $\overline{w}$, $\mathrm{N}(w)$ a finite place, its conjugate, its norm
I, $\mathcal{K}$, x, a an index set, a subgroup, a group element (also a root of unity in Definition 2.2), an integer
φ, π, e, L Euler's function; the circle constant in 2π; the base of exp; in "L-function"
$\mathrm{cs}(d)$, rd, Ψ_{N_0} as in the first part

  read: note built, structured proofs checked. 18 declarations, 71 proof lines.

Heights and the product formula; few translates nearly span; the height of one Gram determinant

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. A *height bound* is defined for families $Z = (Z_{\ell,\iota})$ of complex numbers indexed by the pairs of a prime ℓ and a field isomorphism $\iota\colon \mathbb{C} \to \bar{\mathbb{Q}}_\ell$: one auxiliary number $H \neq 0$ may be multiplied in, and the bound adds the logarithmic size of all conjugates of H to the ℓ-adic sizes of the numbers $H\,Z_{\ell,\iota}$, summed over ℓ. Such bounds add in products, and the product formula, applied to the norm of H, shows that a bound for the constant family 1 is non-negative (Theorem 1). This lets the argument compare ℓ-adic estimates that are obtained with a different auxiliary object at every embedding. Theorem 2 bounds the height of a family of ratios of Gram determinants, a twisted one at each embedding over one untwisted one, by the size of the untwisted determinant, plus twice an index, plus ν times a height bound for a family of scalars. The unit also holds linear algebra for another part of the argument: if the translates of a linear map are spread, few of them nearly span the target (Theorem 3); and two inequalities, one of Fourier type over a finite field, one of Hilbert–Schmidt type.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, of the Riemann hypothesis and of its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles with Lean v4.35.0 against a pinned version of the library Mathlib and that Lean's kernel accepted the proofs; an independent build is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note treats one unit of the artifact, the folder on heights: all 18 of its 18 declarations. Their proofs are given in full. Taken for granted are three results of the background library of the artifact, stated as Inputs 1 to 3 with the units that own them, and standard facts of Mathlib, which are named where they are used. Every statement was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 27 declarations.

1 Heights, and the three main statements

Throughout, ℓ is a prime number, $\mathbb{Q}_\ell$ is the field of ℓ-adic numbers, $\bar{\mathbb{Q}}_\ell$ is an algebraic closure of $\mathbb{Q}_\ell$, and $\mathbb{C}_\ell$ is the completion of $\bar{\mathbb{Q}}_\ell$. On these three fields $|\cdot|_\ell$ is the absolute value with $|\ell|_\ell = 1/\ell$, and $|\cdot|$ is the usual absolute value of $\mathbb{C}$. The group $\mathrm{Aut}(\mathbb{C})$ consists of all field automorphisms of $\mathbb{C}$, continuous or not.

Definition 1.1 (the index set)**.** $\mathcal{I}$ is the set of all pairs (ℓ, ι) of a prime number ℓ and an isomorphism of rings $\iota\colon \mathbb{C} \to \bar{\mathbb{Q}}_\ell$. In this note a *family indexed by* $\mathcal{I}$ is a

family $Z = (Z_{\ell,\iota})$ of complex numbers, one for each pair (ℓ, ι) in $\mathcal{I}$. Such families are multiplied entry by entry, and 1 also denotes the family all of whose entries are 1.

LEAN `PrimePadicIso`

Isomorphisms ι exist for every ℓ, because $\mathbb{C}$ and $\bar{\mathbb{Q}}_\ell$ are algebraically closed fields of characteristic 0 and of the same cardinality (Inputs 2 and 3 in §2). None of them is continuous and none is distinguished. The index set is a way to speak of all embeddings into $\bar{\mathbb{Q}}_\ell$ of all number fields at once: the restrictions of the isomorphisms ι to a number field contained in $\mathbb{C}$ are exactly its field embeddings into $\bar{\mathbb{Q}}_\ell$, again by Input 2. So for a complex number that is algebraic over $\mathbb{Q}$, its images under all ι are its conjugates in $\bar{\mathbb{Q}}_\ell$, just as its images under $\mathrm{Aut}(\mathbb{C})$ are its conjugates in $\mathbb{C}$. The entries of a family may depend on (ℓ, ι), and in the argument they do.

Definition 1.2 (height at most h)**.** Let h be a real number and $Z = (Z_{\ell,\iota})$ a family indexed by $\mathcal{I}$. We write $\mathrm{ht}(Z) \le h$, and say that Z *has height at most* h, if there are a complex number $H \neq 0$, a real number α and a sequence $\eta = (\eta_0, \eta_1, \eta_2, \dots)$ of real numbers such that

(i) $|\sigma(H)| \le \exp(\alpha)$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$;
(ii) $|\iota(H\, Z_{\ell,\iota})|_\ell \le \exp(\eta_\ell)$ for every $(\ell, \iota) \in \mathcal{I}$;
(iii) there is a natural number n_0 such that $\alpha + \sum_{\ell<n} \eta_\ell \le h$ for every natural number $n \ge n_0$, the sum being over the primes ℓ below n.

LEAN `HeightLe`

The sign $\mathrm{ht}(Z) \le h$ is the name of a relation between h and Z; no number called the height of Z is defined or needed. With $H = 1$ and $\alpha = 0$ the definition asks that the ℓ-adic sizes of the entries, in logarithms and summed over ℓ, be at most h (Lemma 3.2). The number H allows more: it is one number for all (ℓ, ι), a common factor whose size at the archimedean places is paid for in (i). The sequence η is indexed by all natural numbers, as in the formal text; only its terms at the primes matter. Two examples: for an integer $n \ge 1$, the constant family $1/n$ has height at most $\log n$ (take $H = n$, $\alpha = \log n$, $\eta = 0$), and the constant family n has height at most $-\log n$ (take $H = 1/n$, $\alpha = -\log n$, $\eta = 0$). So a height bound says how small a family is ℓ-adically, all primes together, and it may be negative. It is not the height of Diophantine geometry: no positive parts are taken, the archimedean places enter only through the auxiliary number H, and the entries of a family need not be the conjugates of one number. How negative a bound can be is limited by the first main result.

Theorem 1 (the product formula). *Let h be a real number. If the constant family 1 has height at most h, that is, if $\mathrm{ht}(1) \le h$, then $0 \le h$.*

LEAN `HeightLe.nonneg`

This is the only place of the unit where arithmetic enters. The proof (§3) shows that the number H of the definition is algebraic and applies the product formula of $\mathbb{Q}$ to its norm q, a non-zero rational number: the logarithms of the absolute values of q at all places of $\mathbb{Q}$ add up to zero, condition (i) bounds the logarithm at the archimedean place by α times the degree of H, and condition (ii) bounds the logarithm at ℓ by

η_ℓ times the degree. So $\alpha + \sum_{\ell<n} \eta_\ell$ cannot be negative once n exceeds the primes that divide the numerator or the denominator of q. The argument uses Theorem 1 together with the additivity of height bounds in products: if two families Z and Z' have entrywise product 1, then a bound for Z and a bound for Z' add up to a non-negative number (Corollary 3.5). An upper bound for the height of Z' thus becomes a lower bound for every height bound of Z, and this is how a covolume is bounded from below in the proof of Theorem C of the argument (§7).

Gram determinants. Inner products are conjugate-linear in the first variable and linear in the second, as in the library. For a finite family $v = (v_i)_{i\in I}$ of vectors of a complex inner product space, $\mathrm{Gram}(v) = (\langle v_i, v_{i'}\rangle)_{i,i'\in I}$ is its Gram matrix, and for a linear map T defined on these vectors Tv is the family $(Tv_i)_{i\in I}$. For a $\mathbb{C}$-linear map $T\colon W \to \mathcal{H}$ from a finite-dimensional complex inner product space to a complex inner product space, T^*T is the endomorphism of W whose matrix in an orthonormal basis v of W is $\mathrm{Gram}(Tv)$; it does not depend on v. Its determinant $\det(T^*T)$ is a non-negative real number, the square of the factor by which T multiplies volumes, and it is non-zero exactly when T is injective (Lemma 4.1).

Setting 1.3 (a family of linear maps, a basis, and integral structures)**.** Let W be a finite-dimensional complex inner product space, Ξ a set, and $\theta = (\theta_{\ell,\iota})$ a family of elements of Ξ, one for each pair (ℓ, ι) in $\mathcal{I}$. For every $\vartheta \in \Xi$ let $\mathcal{H}_\vartheta$ be a complex inner product space and $T_\vartheta\colon W \to \mathcal{H}_\vartheta$ a $\mathbb{C}$-linear map, and let ϑ_0 be an element of Ξ. Let I be a finite set and $w = (w_i)_{i\in I}$ a family of vectors of W. Let α, δ and h be real numbers, $c = (c_{\ell,\iota})$ a family of complex numbers indexed by $\mathcal{I}$, $\eta = (\eta_0, \eta_1, \eta_2, \dots)$ a sequence of real numbers, and ν a natural number. For every $(\ell, \iota) \in \mathcal{I}$ and every homomorphism of rings $j\colon \mathbb{C} \to \mathbb{C}_\ell$ let $\mathcal{L}_{\ell,\iota}(j)$ be a subset of $\mathcal{H}_{\theta_{\ell,\iota}}$. For such j, the homomorphism $\bar{j}\colon \mathbb{C} \to \mathbb{C}_\ell$ is j preceded by complex conjugation.

Theorem 2 (the height of one Gram determinant). *In Setting 1.3, suppose that*

(a) *the map T_{ϑ_0} is injective;*

(b) *the family w is linearly independent and $\dim W = \#I$, so that w is a basis of W;*

(c) $|\sigma(\det \mathrm{Gram}(T_{\vartheta_0} w))| \leq \exp(\alpha)$ *for every* $\sigma \in \mathrm{Aut}(\mathbb{C})$*;*

(d) $c_{\ell,\iota} \neq 0$ *for every* $(\ell,\iota) \in \mathcal{I}$*, and* $\mathrm{ht}(|c|^{-2}) \leq h$ *for the family* $|c|^{-2} = (|c_{\ell,\iota}|^{-2})$*;*

(e) $\sum_{n \in J} \eta_n \leq \delta$ *for every finite set J of natural numbers;*

(f) *for every $(\ell,\iota) \in \mathcal{I}$, every homomorphism of rings $j\colon \mathbb{C} \to \mathbb{C}_\ell$, every $F \in \mathcal{L}_{\ell,\iota}(\bar{j})$ and every $F' \in \mathcal{L}_{\ell,\iota}(j)$, one has $|j(\langle F, F' \rangle)|_\ell \leq 1$;*

(g) *for every $(\ell,\iota) \in \mathcal{I}$ and every homomorphism of rings $j\colon \mathbb{C} \to \mathbb{C}_\ell$ there is a matrix $u = (u_{ii'})_{i,i' \in I}$ of complex numbers such that*

$$\exp(-\eta_\ell) \cdot |j(c_{\ell,\iota})|_\ell^\nu \;\leq\; |j(\det u)|_\ell$$

and

$$\sum_{i' \in I} u_{ii'}\, T_{\theta_{\ell,\iota}}(w_{i'}) \in \mathcal{L}_{\ell,\iota}(j) \quad \text{for all } i \in I.$$

Then the family $Z = (Z_{\ell,\iota})$ of the ratios

$$Z_{\ell,\iota} \;=\; \frac{\det(T^*_{\theta_{\ell,\iota}} T_{\theta_{\ell,\iota}})}{\det(T^*_{\vartheta_0} T_{\vartheta_0})}$$

satisfies $\mathrm{ht}(Z) \leq \alpha + 2\delta + \nu h$.

LEAN `one_determinant`

In words: when T_ϑ is injective, the vectors $T_\vartheta w_i$ form a basis of $T_\vartheta(W)$, and $\det \mathrm{Gram}(T_\vartheta w)$ is the square of the volume of the parallelotope that they span (the squared covolume of the overview of the handout, at the identity of $\mathrm{Aut}(\mathbb{C})$). Hypothesis (c) bounds this number at the base index ϑ_0, at all its conjugates. The sets $\mathcal{L}_{\ell,\iota}(j)$ play the part of the j-integral vectors: by (f) the pairing of a $\bar{j}$-integral vector with a j-integral one is j-integral. Hypothesis (g) says that, at the index $\theta_{\ell,\iota}$ chosen for the pair (ℓ,ι), suitable combinations of the vectors $T_{\theta_{\ell,\iota}} w_i$ are integral, with a matrix of combination whose determinant is not too small: η_ℓ bounds the logarithm of an index, and $c_{\ell,\iota}$ is a scalar that ν of the vectors are allowed to carry. The conclusion compares the covolume at $\theta_{\ell,\iota}$ with the covolume at ϑ_0: the ratio of their squares is ℓ-adically small, all primes together, up to the archimedean size α, twice the index δ and the cost h of each of the ν scalars. The index counts twice because the proof needs one integral combination for the embedding j_ι of Definition 2.1 and one for its conjugate. The square of an index appears as it does for lattices over $\mathbb{Z}$, where a lattice with integral Gram matrix that has index n in another one forces n^2 times the Gram determinant of the latter to be an integer.

Spread families. The third statement is linear algebra over $\mathbb{C}$.

Definition 1.4 (spread families of linear maps)**.** Let U and W be complex vector spaces, Ω a set, $B = (B_\gamma)_{\gamma \in \Omega}$ a family of $\mathbb{C}$-linear maps $B_\gamma\colon U \to W$, and ε a real

number. The family B is *ε-spread*, in symbols $\mathrm{Spread}_\varepsilon(B)$, if for every linear subspace $W' \subseteq W$ there is a $\gamma \in \Omega$ with

$$\dim B_\gamma^{-1}(W') \;\le\; \Big(\frac{1}{2}\Big(1+\frac{\dim W'}{\dim W}\Big)+\varepsilon\Big)\cdot \dim U.$$

LEAN `IsSpread`

If B_γ is injective and its image is in general position with respect to W', the preimage of W' has about the share $\dim W'/\dim W$ of the dimension of U. The definition asks less: for every W' some member of the family must pull W' back to at most the mean of this share and 1, up to ε.

Theorem 3 (few translates nearly span). *Let U be a finite-dimensional complex vector space with $U \neq 0$, let W be a finite-dimensional complex inner product space, Ω a set, $B = (B_\gamma)_{\gamma\in\Omega}$ a family of $\mathbb{C}$-linear maps $B_\gamma\colon U \to W$, and $\varepsilon > 0$ a real number. If $\mathrm{Spread}_\varepsilon(B)$, then there is a finite subset $\mathcal{T} \subseteq \Omega$ with*

$$\#\mathcal{T}\cdot\dim U \;\le\; 5\,\dim W\cdot\log(1+\varepsilon^{-1})$$

and

$$(1-4\varepsilon)\,\dim W \;\le\; \dim\sum_{\gamma\in\mathcal{T}} B_\gamma(U).$$

LEAN `exists_few_translates`

Each image $B_\gamma(U)$ has dimension at most $\dim U$, so at least $(1-4\varepsilon)\dim W/\dim U$ members are needed to span a subspace of dimension $(1-4\varepsilon)\dim W$. The theorem says that this least number, times $5\log(1+\varepsilon^{-1})/(1-4\varepsilon)$, suffices. In the argument the maps B_γ are the translates of one map by the elements γ of a finite group, whence the name.

2 The setting

Conventions. The natural numbers are $0, 1, 2, \dots$, and $\#I$ is the number of elements of a finite set I. The letter ℓ always denotes a prime number; a sum $\sum_{\ell<n}$ runs over the primes below n. Vector spaces are over $\mathbb{C}$ unless a finite field is named. A *complex inner product space* is a complex vector space with a positive definite hermitian form $\langle\cdot,\cdot\rangle$, conjugate-linear in the first variable, and $\|F\|^2 = \langle F, F\rangle$; completeness is not assumed. For a finite set I, the space $\mathbb{C}^I$ has the inner product for which the standard basis $\mathbf{1} = (\mathbf{1}_i)_{i\in I}$ is orthonormal. The tensor product of two complex inner product spaces carries the inner product with $\langle F_1\otimes F_2, F_1'\otimes F_2'\rangle = \langle F_1, F_1'\rangle\langle F_2, F_2'\rangle$. For a finite-dimensional subspace $\mathcal{H}'$ of an inner product space $\mathcal{H}$, $p_{\mathcal{H}'}$ is the orthogonal projection of $\mathcal{H}$ onto $\mathcal{H}'$. The functions of the library are defined everywhere: the logarithm of a real number q is $\log|q|$ for $q \neq 0$ and 0 for $q = 0$; a quotient with denominator 0 is 0; and the dimension of a vector space that is not finite-dimensional is 0. These conventions enter two statements only, Lemma 3.4 for $q = 0$ and Definition 1.4, which the formal text states without assuming finite dimension. The declarations of this unit take no ambient object that is fixed once for the whole note: each statement below introduces the spaces, sets and maps it is about.

Letters local to this note. Sections 1 to 6 do not depend on the data of the proof, and ten letters have there a meaning of their own, recorded in the notation list: ξ and ρ (vectors with coordinates in a finite set), τ and τ_0 (homomorphisms of rings), c (a family of scalars), q (a rational number), Ψ (an additive character), ω (a function on a group), Γ_ϑ (a Gram determinant) and Ω (an index set). In the overview of the handout and in Chapter III these letters denote Dirichlet characters, zeros, infinite places, a residue class, the rational number of Theorem A, cyclotomic polynomials, residue characters, groups of rational points and a period. None of those objects occurs in these sections, and of the local letters only c returns in Section 7, in its role of Theorem 2.

Definition 2.1 (the embedding attached to ι)**.** For a prime number ℓ and an isomorphism of rings $\iota\colon \mathbb{C} \to \bar{\mathbb{Q}}_\ell$, the homomorphism of rings $j_\iota\colon \mathbb{C} \to \mathbb{C}_\ell$ is ι followed by the inclusion of $\bar{\mathbb{Q}}_\ell$ in $\mathbb{C}_\ell$. So $|j_\iota(H)|_\ell = |\iota(H)|_\ell$ for every complex number H.

LEAN `complexToCp` · a definition of the background library, in the unit *Lib.ClassField.Places*

Inputs from the background library. The three results below are taken for granted in this note. They are theorems of the background library of the artifact, which proves them from Mathlib; the units that own them are named, and none of these units has been read yet.

Input 1 (a number bounded at all 2-adic identifications is algebraic; unit *Lib.CM.Genus*). *Let H be a complex number and Y a real number. If $|j_\iota(H)|_2 \le Y$ for every isomorphism of rings $\iota\colon \mathbb{C} \to \bar{\mathbb{Q}}_2$, then H is algebraic over $\mathbb{Q}$.*

Input 2 (embeddings extend to isomorphisms; unit *Lib.General.LinearAlgebra*). *Let L be an algebraically closed field of the same cardinality as $\mathbb{C}$, and let τ_0 and τ be injective homomorphisms of rings from one countable commutative ring to $\mathbb{C}$ and to L, respectively. Then there is an isomorphism of rings $\iota\colon \mathbb{C} \to L$ with $\iota \circ \tau_0 = \tau$.*

Input 3 (cardinality; unit *Lib.PadicHodge.PeriodRings*). *For every prime number ℓ, the field $\bar{\mathbb{Q}}_\ell$ has the same cardinality as $\mathbb{C}$.*

LEAN `isAlgebraic_of_padic` · `exists_ringEquiv_extend` · `mk_complex_eq_mk_padicAlgCl`

Input 2 is a form of Steinitz's theorem that an algebraically closed field is determined by its characteristic and its transcendence degree: the catalogue of this handout records it under Steinitz [St] as a special case, that of two algebraically closed fields of characteristic 0 and of the cardinality of the continuum, with an isomorphism that extends a given one between countable subrings; the place in [St] is not confirmed. For Inputs 1 and 3 the catalogue has no reference: reference to be confirmed. Both are elementary, the first once Input 2 is granted. Input 3 holds because $\mathbb{Q}_\ell$ has the cardinality of the continuum and an algebraic extension of an infinite field has the cardinality of that field. Input 1 has a short formal proof, which was read: if H were transcendental, one would choose an element of $\bar{\mathbb{Q}}_2$ that is transcendental over $\mathbb{Q}$ and of absolute value greater than Y (the algebraic elements are countable, so the others are dense), and Input 2, applied to the two embeddings of the polynomial ring over $\mathbb{Q}$ in one variable that send the variable to H and to this element, would give an ι violating the bound.

Facts of Mathlib. The proofs below also use standard facts that the formal proofs take from Mathlib, the mathematical library of Lean: unique factorisation of integers; that the image of the norm of a finite separable field extension in an algebraically closed field is the product over the embeddings; that $|\cdot|_\ell$ on $\bar{\mathbb{Q}}_\ell$ restricts to the ℓ-adic absolute value on $\mathbb{Q}$; the properties of Gram matrices collected in Lemma 4.1, where a short proof is given; Bessel's inequality, Parseval's identity and Pythagoras' theorem in inner product spaces; the trace of an endomorphism as the sum of its diagonal coefficients in an orthonormal basis; the existence of a non-trivial additive character of a finite field; and elementary linear algebra. Their formal statements were not read: Mathlib is not part of the artifact, and its pinned version was not at hand when this note was written. The dossier of the unit records these facts from their names and from the way they are used.

3 Height bounds and the product formula

In this section Z and Z' are families indexed by $\mathcal{I}$ and h, h' are real numbers; a triple (H, α, η) as in Definition 1.2 is called a *witness* of $\mathrm{ht}(Z) \le h$.

Lemma 3.1 (monotonicity)**.** *Let h and h' be real numbers and Z, Z' families indexed by $\mathcal{I}$. If $\mathrm{ht}(Z) \le h$, if $h \le h'$, and if $|\iota(Z'_{\ell,\iota})|_\ell \le |\iota(Z_{\ell,\iota})|_\ell$ for every $(\ell,\iota) \in \mathcal{I}$, then $\mathrm{ht}(Z') \le h'$.*

Proof. A witness (H, α, η) of $\mathrm{ht}(Z) \le h$ is a witness of $\mathrm{ht}(Z') \le h'$: conditions (i) and (iii) are unchanged or weaker, and

$$|\iota(HZ'_{\ell,\iota})|_\ell = |\iota(H)|_\ell |\iota(Z'_{\ell,\iota})|_\ell \le |\iota(HZ_{\ell,\iota})|_\ell \le \exp(\eta_\ell),$$

because ι is a homomorphism of rings and $|\cdot|_\ell$ is multiplicative. □

LEAN `HeightLe.mono`

Lemma 3.2 (families of bounded entries)**.** *Let h be a real number, Z a family indexed by $\mathcal{I}$, and $\eta = (\eta_0, \eta_1, \eta_2, \dots)$ a sequence of real numbers. If $\sum_{\ell \in J} \eta_\ell \le h$ for every finite set J of prime numbers, and if $|\iota(Z_{\ell,\iota})|_\ell \le \exp(\eta_\ell)$ for every $(\ell,\iota) \in \mathcal{I}$, then $\mathrm{ht}(Z) \le h$.*

Proof. The triple $(1, 0, \eta)$ is a witness: $\sigma(1) = 1$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$, condition (ii) is the second hypothesis, and (iii) holds for every n by the first hypothesis, applied to the set J of the primes below n. □

LEAN `HeightLe.of_le`

Proposition 3.3 (height bounds add in products)**.** *Height bounds have the following three properties.*

(a) *Let h and h' be real numbers and Z, Z' families indexed by $\mathcal{I}$. If $\mathrm{ht}(Z) \le h$ and $\mathrm{ht}(Z') \le h'$, then $\mathrm{ht}(ZZ') \le h + h'$.*

(b) *Let Ω be a set and $I \subseteq \Omega$ a finite subset, and for every $i \in \Omega$ let h_i be a real number and Z_i a family indexed by $\mathcal{I}$. If $\mathrm{ht}(Z_i) \le h_i$ for every $i \in I$, then $\mathrm{ht}(\prod_{i \in I} Z_i) \le \sum_{i \in I} h_i$.*

(c) *Let h be a real number, Z a family indexed by $\mathcal{I}$ with $\mathrm{ht}(Z) \le h$, and n a natural number. Then $\mathrm{ht}(Z^n) \le n\,h$.*

Proof. (a) Let (H, α, η) and (H', α', η') be witnesses, with thresholds n_0 and n_0' in (iii). Then $HH' \neq 0$, $|\sigma(HH')| \leq \exp(\alpha + \alpha')$ for every σ, and

$$|\iota(HH' Z_{\ell,\iota} Z'_{\ell,\iota})|_\ell = |\iota(H Z_{\ell,\iota})|_\ell \cdot |\iota(H' Z'_{\ell,\iota})|_\ell \leq \exp(\eta_\ell + \eta'_\ell) \qquad \text{for every } (\ell, \iota) \in \mathcal{I}.$$

For $n \geq n_0 + n_0'$ both inequalities (iii) hold, and their sum is the inequality (iii) for the triple $(HH', \alpha + \alpha', \eta + \eta')$ and the bound $h + h'$.

(b) By induction on the number of elements of I. If I is empty, the product is the constant family 1 and the sum is 0, and $\mathrm{ht}(1) \leq 0$ by Lemma 3.2 with $\eta = 0$. The step from I to I with one more element is (a).

(c) This is (b) for a set I of n elements, with all h_i equal to h and all Z_i equal to Z. □

LEAN `HeightLe.mul` · `HeightLe.prod` · `HeightLe.pow`

Lemma 3.4 (the product formula for $\mathbb{Q}$)**.** *Let n be a natural number and q a rational number, with numerator q_{num} and denominator $q_{\mathrm{den}} \geq 1$ in lowest terms (for $q = 0$ these are 0 and 1). If $\max(|q_{\mathrm{num}}|, q_{\mathrm{den}}) < n$, then*

$$\log|q| + \sum_{\ell < n} \log|q|_\ell = 0,$$

where $|q|_\ell$ is the ℓ-adic absolute value of q, the sum is over the primes ℓ below n, and for $q = 0$ all the logarithms are read as 0.

Proof. For $q = 0$ there is nothing to prove. Let $q \neq 0$. A prime that divides q_{num} or q_{den} is at most $\max(|q_{\mathrm{num}}|, q_{\mathrm{den}})$, hence below n. Write ord_ℓ for the exponent of ℓ in an integer. By unique factorisation,

$$\log|q_{\mathrm{num}}| = \sum_{\ell < n} \mathrm{ord}_\ell(q_{\mathrm{num}}) \log \ell \qquad \text{and} \qquad \log q_{\mathrm{den}} = \sum_{\ell < n} \mathrm{ord}_\ell(q_{\mathrm{den}}) \log \ell.$$

Since $\log|q|_\ell = (\mathrm{ord}_\ell(q_{\mathrm{den}}) - \mathrm{ord}_\ell(q_{\mathrm{num}})) \log \ell$, the sum of the numbers $\log|q|_\ell$ over the primes $\ell < n$ is $\log q_{\mathrm{den}} - \log|q_{\mathrm{num}}| = -\log|q|$. □

LEAN `log_product_formula`

Proof of Theorem 1. Let (H, α, η) be a witness of $\mathrm{ht}(1) \leq h$, with threshold n_0 in (iii). Here (ii) reads $|\iota(H)|_\ell \leq \exp(\eta_\ell)$ for all $(\ell, \iota) \in \mathcal{I}$.

The number H is algebraic. By (ii) for $\ell = 2$ and Definition 2.1, $|j_\iota(H)|_2 \leq \exp(\eta_2)$ for every isomorphism $\iota \colon \mathbb{C} \to \bar{\mathbb{Q}}_2$, and Input 1 applies. So $\mathbb{Q}(H)$ is a number field. Write $\deg H$ for its degree over $\mathbb{Q}$, and let $q = \mathrm{Nm}_{\mathbb{Q}(H)/\mathbb{Q}}(H)$ be the norm of H, a rational number, non-zero because $H \neq 0$.

Local bounds. We claim that

$$\log|q| \leq \deg H \cdot \alpha \qquad \text{and} \qquad \log|q|_\ell \leq \deg H \cdot \eta_\ell \quad \text{for every prime } \ell. \tag{1}$$

Fix ℓ. The image of q in $\bar{\mathbb{Q}}_\ell$ is the product of the numbers $\tau(H)$ over the $\deg H$ field embeddings $\tau \colon \mathbb{Q}(H) \to \bar{\mathbb{Q}}_\ell$. Each τ is the restriction of an isomorphism $\iota \colon \mathbb{C} \to \bar{\mathbb{Q}}_\ell$: this is Input 2 for the field $L = \bar{\mathbb{Q}}_\ell$, which has the cardinality of $\mathbb{C}$ by Input 3, for the countable ring $\mathbb{Q}(H)$, for its inclusion τ_0 in $\mathbb{C}$, and for τ. Hence $|\tau(H)|_\ell = |\iota(H)|_\ell \leq \exp(\eta_\ell)$ by (ii), and $|q|_\ell \leq \exp(\deg H \cdot \eta_\ell)$, because $|\cdot|_\ell$ on $\bar{\mathbb{Q}}_\ell$ restricts to the ℓ-adic absolute value on $\mathbb{Q}$. The first inequality of (1) is proved in the same way with $\mathbb{C}$ in the

place of $\bar{\mathbb{Q}}_\ell$: the embeddings $\mathbb{Q}(H) \to \mathbb{C}$ are the restrictions of the automorphisms $\sigma \in \mathrm{Aut}(\mathbb{C})$ by Input 2 for $L = \mathbb{C}$, and (i) bounds each $|\sigma(H)|$ by $\exp(\alpha)$.

The product formula. Put $n = n_0 + \max(|q_{\mathrm{num}}|, q_{\mathrm{den}}) + 1$. By (iii), by (1) and by Lemma 3.4,

$$\deg H \cdot h \;\geq\; \deg H \cdot \Big(\alpha + \sum_{\ell<n} \eta_\ell\Big) \;\geq\; \log|q| + \sum_{\ell<n} \log|q|_\ell \;=\; 0,$$

and $\deg H \geq 1$. □

Corollary 3.5 (the form in which Theorem 1 is used)**.** *Let h and h' be real numbers and Z, Z' families indexed by $\mathcal{I}$ with $Z_{\ell,\iota} Z'_{\ell,\iota} = 1$ for every $(\ell, \iota) \in \mathcal{I}$. If $\mathrm{ht}(Z) \leq h$ and $\mathrm{ht}(Z') \leq h'$, then $h + h' \geq 0$.*

Proof. By Proposition 3.3(a), $\mathrm{ht}(1) \leq h + h'$; now apply Theorem 1. □

The corollary is not a declaration of the formal text; it is the last step of the formal proof of Theorem C of the argument, where it is applied to the square of one family and to a second family (§7).

Remark 3.6 (constant families)**.** The proof of Theorem 1 gives more, by the same steps. Let Z be the constant family with value a non-zero algebraic number, and let $\bar{h}$ be the mean of the logarithms of the absolute values of its conjugates in $\mathbb{C}$. If $\mathrm{ht}(Z) \leq h$, then $h \geq -\bar{h}$. Indeed, for a witness (H, α, η) the number H is again algebraic, and one applies the product formula to the norm of H times the value of Z, taken from the number field that the two generate. So a height bound for a constant family cannot fall below what the product formula allows, and the two examples of §1 are best possible. This remark is ours; the formal text has only the case of the constant family 1.

4 The height of one Gram determinant

Lemma 4.1 (Gram matrices)**.** *Let I be a finite set and $F = (F_i)_{i \in I}$ a family of vectors of a complex inner product space.*

(1) $\det \mathrm{Gram}(F) \neq 0$ *if and only if the family F is linearly independent.*

(2) *For matrices $u = (u_{ii'})$ and $u' = (u'_{ii'})$ of complex numbers indexed by $I \times I$, put $F'_i = \sum_{i_1 \in I} u'_{ii_1} F_{i_1}$ and $F''_i = \sum_{i_1 \in I} u_{ii_1} F_{i_1}$ for $i \in I$. Then*

$$\big(\langle F'_i, F''_{i'} \rangle\big)_{i,i' \in I} \;=\; \overline{u'} \cdot \mathrm{Gram}(F) \cdot u^{\mathrm{t}},$$

where $\overline{u'}$ is the matrix of the complex conjugates of the entries of u' and u^{t} is the transpose of u.

(3) *Let W be a finite-dimensional complex inner product space with $\dim W = \#I$, let $w = (w_i)_{i \in I}$ be a family of vectors of W, and let T be a $\mathbb{C}$-linear map from W to a complex inner product space. Then $\det \mathrm{Gram}(Tw) = \det(T^*T) \cdot \det \mathrm{Gram}(w)$. In particular $\det(T^*T) \neq 0$ if and only if T is injective.*

Proof. Write $[F]$ for the linear map from $\mathbb{C}^I$ that sends the standard basis vector $\mathbf{1}_i$ to F_i. Then $\mathrm{Gram}(F)$ is the matrix of the hermitian form $(\xi,\xi') \mapsto \langle [F]\xi, [F]\xi'\rangle$ on $\mathbb{C}^I$. This form is positive semi-definite, and it is definite exactly when $[F]$ is injective, which is (1). Statement (2) is the expansion of $\langle F_i', F_{i'}''\rangle$ by sesquilinearity. For (3), choose an orthonormal basis v of W indexed by I, and let u be the matrix with $w_{i'} = \sum_{i\in I} u_{i'i} v_i$. By (2), applied to the family Tv and then to the family v, $\mathrm{Gram}(Tw) = \overline{u}\cdot \mathrm{Gram}(Tv)\cdot u^{\mathrm{t}}$ and $\mathrm{Gram}(w) = \overline{u}\cdot u^{\mathrm{t}}$. As $\mathrm{Gram}(Tv)$ is the matrix of T^*T in the basis v, taking determinants gives the formula. The last assertion follows from (1) for the family Tv. □

LEAN facts of Mathlib; the formal text writes $\det(T^*T)$ as the square of a function of Mathlib that is the volume factor of a linear map

Proof of Theorem 2. For every ϑ in Ξ put $\Gamma_\vartheta = \det \mathrm{Gram}(T_\vartheta w)$. By (b) and Lemma 4.1(1) the number $\det\mathrm{Gram}(w)$ is not zero, and by Lemma 4.1(3)

$$\Gamma_\vartheta \;=\; \det(T_\vartheta^* T_\vartheta)\cdot \det \mathrm{Gram}(w) \qquad \text{for every } \vartheta\in\Xi.$$

By (a), $\Gamma_{\vartheta_0}\neq 0$. So the family of the theorem is $Z_{\ell,\iota} = \Gamma_{\theta_{\ell,\iota}}/\Gamma_{\vartheta_0}$.

Reduction. Let Z' be the family with entries $Z'_{\ell,\iota} = Z_{\ell,\iota}\,|c_{\ell,\iota}|^{2\nu}$. Then Z is the product of Z' and of the ν-th power of the family $|c|^{-2}$, and this power has height at most νh by (d) and Proposition 3.3(c). By Proposition 3.3(a) it suffices to show that $\mathrm{ht}(Z') \le \alpha + 2\delta$. We claim that the triple $(\Gamma_{\vartheta_0}, \alpha, 2\eta)$ is a witness. Condition (i) is (c). Condition (iii) holds for every n, by (e) for the set J of the primes below n. Condition (ii) is the inequality

$$\big|\iota(\Gamma_{\theta_{\ell,\iota}}\cdot |c_{\ell,\iota}|^{2\nu})\big|_\ell \;\le\; \exp(2\eta_\ell) \qquad \text{for every } (\ell,\iota)\in\mathcal{I}, \tag{2}$$

which remains to be proved.

The ℓ-adic bound. Fix $(\ell,\iota)\in\mathcal{I}$ and put $j = j_\iota$, so that $|\iota(\,\cdot\,)|_\ell = |j(\,\cdot\,)|_\ell$. Let u be a matrix as in (g) for (ℓ,ι) and j, and u' a matrix as in (g) for (ℓ,ι) and $\bar{j}$. Since $\bar{j}$ is j preceded by complex conjugation, the two inequalities of (g) read

$$\exp(-\eta_\ell)\,|j(c_{\ell,\iota})|_\ell^\nu \le |j(\det u)|_\ell \qquad\text{and}\qquad \exp(-\eta_\ell)\,|j(\overline{c_{\ell,\iota}})|_\ell^\nu \le |j(\det \overline{u'})|_\ell. \tag{3}$$

Put $F_i' = \sum_{i_1\in I} u'_{ii_1} T_{\theta_{\ell,\iota}}(w_{i_1})$ and $F_i'' = \sum_{i_1\in I} u_{ii_1} T_{\theta_{\ell,\iota}}(w_{i_1})$ for $i\in I$. By (g) the vectors F_i' lie in $\mathcal{L}_{\ell,\iota}(\bar{j})$ and the vectors F_i'' lie in $\mathcal{L}_{\ell,\iota}(j)$, so by (f) every entry of the matrix $(\langle F_i', F_{i'}''\rangle)_{i,i'\in I}$ lies in the set O_j of the complex numbers whose image under j has absolute value at most 1. This set is a subring of $\mathbb{C}$, because $|\,\cdot\,|_\ell$ is non-archimedean; hence the determinant of the matrix lies in O_j as well. By Lemma 4.1(2) the matrix is $\overline{u'}\cdot \mathrm{Gram}(T_{\theta_{\ell,\iota}} w)\cdot u^{\mathrm{t}}$, with determinant $\det\overline{u'}\cdot\Gamma_{\theta_{\ell,\iota}}\cdot\det u$. Therefore

$$|j(\det\overline{u'})|_\ell \cdot |j(\Gamma_{\theta_{\ell,\iota}})|_\ell \cdot |j(\det u)|_\ell \;\le\; 1. \tag{4}$$

Now $|c_{\ell,\iota}|^2 = \overline{c_{\ell,\iota}}\cdot c_{\ell,\iota}$, so by (3) and then (4)

$$\big|j(\Gamma_{\theta_{\ell,\iota}}|c_{\ell,\iota}|^{2\nu})\big|_\ell \;\le\; |j(\Gamma_{\theta_{\ell,\iota}})|_\ell\cdot\exp(2\eta_\ell)\cdot|j(\det\overline{u'})|_\ell\cdot|j(\det u)|_\ell \;\le\; \exp(2\eta_\ell).$$

This is (2). □

LEAN `one_determinant` · uses `HeightLe.mul`, `HeightLe.pow`, `complexToCp`, and from the background library `IsIntMatrix` and `IsIntMatrix.det_mem`: a determinant of a matrix with entries in a subring lies in the subring

The proof uses hypotheses (f) and (g) only for the two homomorphisms j_ι and its conjugate, and it uses nothing about the sets $\mathcal{L}_{\ell,\iota}(j)$ beyond (f) and (g). The inner product of W does not matter either: by Lemma 4.1(3) the ratio $Z_{\ell,\iota}$ is a ratio of Gram determinants of images of the basis w.

Completing a family to a basis. Theorem 2 needs a basis of W. In the argument a linearly independent family is given, and it is completed by vectors of a second kind, for which hypothesis (g) holds with the scalars $c_{\ell,\iota}$. The following lemma provides the completion.

Lemma 4.2 (extension to a basis from a spanning set)**.** *Let W be a finite-dimensional complex vector space, n a natural number, S a subset of W that spans W, and $y_1, \dots, y_n$ linearly independent vectors of W. Then there are a natural number n' and vectors $z_1, \dots, z_{n'}$ in S such that $y_1, \dots, y_n, z_1, \dots, z_{n'}$ are linearly independent and $\dim W = n + n'$.*

Proof. Let W_y be the span of $y_1, \dots, y_n$; it has dimension n. The images of the elements of S span the quotient W/W_y, so there are $z_1, \dots, z_{n'}$ in S whose images form a basis of W/W_y, and $n' = \dim W - n$. A linear relation among $y_1, \dots, y_n, z_1, \dots, z_{n'}$ becomes, modulo W_y, a relation among the images of the z_i, so its coefficients at the z_i vanish; what is left is a relation among the y_i, whose coefficients vanish too. □

LEAN `exists_extend_basis_of_span_eq_top`

5 Few translates nearly span

Proof of Theorem 3. If $\dim W = 0$, the empty set has the two properties. Let $\dim W \geq 1$. For a finite subset $\mathcal{T}' \subseteq \Omega$ put

$$W_{\mathcal{T}'} = \sum_{\gamma \in \mathcal{T}'} B_\gamma(U), \qquad \operatorname{codim} W_{\mathcal{T}'} = \dim W - \dim W_{\mathcal{T}'},$$

$$\Pi(\mathcal{T}') \;=\; \#\mathcal{T}' \cdot \dim U \;+\; 5\,\dim W \cdot \log\Bigl(1 + \frac{\operatorname{codim} W_{\mathcal{T}'}}{\varepsilon\,\dim W}\Bigr).$$

Call $\mathcal{T}'$ *admissible* if $\Pi(\mathcal{T}') \leq 5\,\dim W \cdot \log(1+\varepsilon^{-1})$. The empty set is admissible, with equality. Among the admissible sets choose one, $\mathcal{T}$, for which $\dim W_{\mathcal{T}}$ is largest. The logarithm in $\Pi(\mathcal{T})$ is non-negative, so

$$\#\mathcal{T} \cdot \dim U \;\leq\; \Pi(\mathcal{T}) \;\leq\; 5\,\dim W \cdot \log(1+\varepsilon^{-1})\,:$$

this is the first inequality.

For the second, suppose that $\dim W_{\mathcal{T}} < (1-4\varepsilon)\dim W$, that is,

$$\operatorname{codim} W_{\mathcal{T}} \;>\; 4\,\varepsilon\,\dim W. \tag{5}$$

Since B is ε-spread, there is a $\gamma \in \Omega$ with

$$\dim B_\gamma^{-1}(W_{\mathcal{T}}) \;\leq\; \Bigl(\frac{1}{2}\Bigl(1 + \frac{\dim W_{\mathcal{T}}}{\dim W}\Bigr) + \varepsilon\Bigr)\dim U \;=\; \Bigl(1 - \frac{\operatorname{codim} W_{\mathcal{T}}}{2\dim W} + \varepsilon\Bigr)\dim U.$$

Let rk be the rank of the map $U \to W/W_{\mathcal{T}}$ induced by B_γ. Its kernel is $B_\gamma^{-1}(W_{\mathcal{T}})$, so

$$\mathrm{rk} \;=\; \dim U - \dim B_\gamma^{-1}(W_{\mathcal{T}}) \;\geq\; \Bigl(\frac{\operatorname{codim} W_{\mathcal{T}}}{2\dim W} - \varepsilon\Bigr)\dim U \;>\; \frac{\operatorname{codim} W_{\mathcal{T}}}{4\dim W}\cdot\dim U \;>\; 0, \tag{6}$$

the last two inequalities by (5) and $\dim U \geq 1$. Put $\mathcal{T}'' = \mathcal{T} \cup \{\gamma\}$. Then $W_{\mathcal{T}''} = W_{\mathcal{T}} + B_\gamma(U)$ and $\operatorname{codim} W_{\mathcal{T}''} = \operatorname{codim} W_{\mathcal{T}} - \mathrm{rk}$, so that the quotient of the arguments of the two logarithms is $1 - \mathrm{rk}/(\varepsilon \dim W + \operatorname{codim} W_{\mathcal{T}})$. This number lies in the interval from 0 to 1, and the logarithm of a positive number is at most that number minus 1. As $\mathcal{T}''$ has at most one element more than $\mathcal{T}$,

$$\begin{aligned} \Pi(\mathcal{T}'') - \Pi(\mathcal{T}) &\leq \dim U + 5 \dim W \cdot \log\Bigl(1 - \frac{\mathrm{rk}}{\varepsilon \dim W + \operatorname{codim} W_{\mathcal{T}}}\Bigr) \\ &\leq \dim U - \frac{5 \dim W \cdot \mathrm{rk}}{\varepsilon \dim W + \operatorname{codim} W_{\mathcal{T}}}. \end{aligned}$$

By the first inequality of (6) and by (5),

$$5 \dim W \cdot \mathrm{rk} \;\geq\; \Bigl(\frac{5}{2} \operatorname{codim} W_{\mathcal{T}} - 5\varepsilon \dim W\Bigr) \dim U \;\geq\; (\operatorname{codim} W_{\mathcal{T}} + \varepsilon \dim W) \dim U,$$

the second step because $\frac{3}{2} \operatorname{codim} W_{\mathcal{T}} \geq 6\varepsilon \dim W$. Hence $\Pi(\mathcal{T}'') \leq \Pi(\mathcal{T})$, and $\mathcal{T}''$ is admissible. By the choice of $\mathcal{T}$, $\dim W_{\mathcal{T}''} \leq \dim W_{\mathcal{T}}$, so $B_\gamma(U) \subseteq W_{\mathcal{T}}$ and $\mathrm{rk} = 0$, against (6). □

LEAN `exists_few_translates` · uses `IsSpread`

The potential Π explains the two constants. Adding a member costs $\dim U$ in the first term. The spread property guarantees that a suitable member lowers the codimension by a fixed share of what is left, as long as (5) holds, and the logarithm turns this into a drop of the second term by at least $\dim U$. The factor 5 is what makes the last display true under (5), and 4ε is where the process stops.

6 Two inequalities behind the spread property

The hypothesis of Theorem 3 is proved in another chapter, by a second moment over a finite group. The unit on heights holds the two general inequalities of that proof. Both concern a finite group G and a map from G to an inner product space whose inner products depend only on the quotient of the two arguments.

Lemma 6.1 (inner products of sums over a group)**.** *Let G be a finite group, $\mathcal{H}$ a complex inner product space, $v\colon G \to \mathcal{H}$ and $w\colon G \to \mathcal{H}$ two maps, and $\omega\colon G \to \mathbb{C}$ a function such that $\langle v(\gamma), w(\gamma')\rangle = \omega(\gamma^{-1}\gamma')$ for all $\gamma, \gamma' \in G$. Then*

$$\Bigl\langle \sum_{\gamma \in G} v(\gamma), \sum_{\gamma \in G} w(\gamma) \Bigr\rangle \;=\; \#G \cdot \sum_{\gamma \in G} \omega(\gamma).$$

Proof. The left side is $\sum_\gamma \sum_{\gamma'} \omega(\gamma^{-1}\gamma')$, and for each γ the map $\gamma' \mapsto \gamma^{-1}\gamma'$ is a bijection of G. □

LEAN `inner_sum_sum_eq_card_mul`

In the next statement $\mathbb{F}$ is a finite field, $\mathbb{F}^I$ is the space of vectors indexed by a finite set I, and $\mathrm{GL}_I(\mathbb{F})$ is the group of invertible matrices indexed by $I \times I$, which acts on $\mathbb{F}^I$. A function ω as in (b) below is a function of positive type on G.

Proposition 6.2 (singular minors are rare)**.** *Let G be a finite group, $\mathcal{H}$ a complex inner product space and $v\colon G \to \mathcal{H}$ a map. Let $\mathbb{F}$ be a finite field, I and I' finite sets, $\pi\colon G \to \mathrm{GL}_I(\mathbb{F})$ a homomorphism of groups, and $A = (A_1, A_0)$ a pair of matrices over $\mathbb{F}$ with rows indexed by I and columns indexed by I'. Let $\omega\colon G \to \mathbb{R}$ be a function and Y a real number. Suppose that*

(a) $\omega(\gamma) \geq 0$ *for every* $\gamma \in G$*;*

(b) $\langle v(\gamma), v(\gamma')\rangle = \omega(\gamma^{-1}\gamma')$ *for all* $\gamma, \gamma' \in G$*;*

(c) $Y \geq 0$*;*

(d) *for every non-zero vector* $\xi \in \mathbb{F}^{I'}$*, the sum of* $\omega(\gamma)$ *over all* $\gamma \in G$ *such that* $(\pi(\gamma)^{\mathrm{t}})^{-1} A_1 \xi = A_1 \xi$ *is at most* Y*, and so is the sum of* $\omega(\gamma)$ *over all* $\gamma \in G$ *such that* $\pi(\gamma) A_0 \xi = A_0 \xi$*.*

Then

$$\#\mathbb{F} \cdot \sum_{\substack{\gamma \in G \\ \det(A_1^{\mathrm{t}} \pi(\gamma) A_0) = 0}} \omega(\gamma) \;\leq\; 2 \sum_{\gamma \in G} \omega(\gamma) \;+\; (\#\mathbb{F})^{\#I'} \sqrt{(\#\mathbb{F})^{\#I}} \cdot Y.$$

The matrix $A_1^{\mathrm{t}} \pi(\gamma) A_0$ is square, indexed by $I' \times I'$. If the two stabilisers in (d) carry little of the mass of ω, the proposition says that the set where this matrix is singular carries at most about the share $2/\#\mathbb{F}$ of the mass.

Proof. Fix a non-trivial character Ψ of the additive group of $\mathbb{F}$; its values have absolute value 1. For a finite set I and ρ, ρ' in $\mathbb{F}^I$ write $\rho \cdot \rho' = \sum_{i \in I} \rho_i \rho'_i$. The sum of a non-trivial character over a finite group is zero, and multiplication by a non-zero element of $\mathbb{F}$ is a bijection of $\mathbb{F}$. Hence, coordinate by coordinate,

$$\sum_{\rho' \in \mathbb{F}^I} \Psi(\rho \cdot \rho') \;=\; (\#\mathbb{F})^{\#I} \;\text{ if } \rho = 0, \qquad \text{and} \qquad = 0 \;\text{ otherwise.} \tag{7}$$

For $\xi_1, \xi_0 \in \mathbb{F}^{I'}$ and $\gamma \in G$ put $\omega_{\xi_1, \xi_0}(\gamma) = \Psi\big(\xi_1 \cdot A_1^{\mathrm{t}} \pi(\gamma) A_0\, \xi_0\big)\, \omega(\gamma)$.

Step 1. Fix γ and ξ_1. By (7) for the set I', the mean over ξ_0 of the numbers $\Psi(\xi_1 \cdot A_1^{\mathrm{t}} \pi(\gamma) A_0\, \xi_0)$ is 1 if $\xi_1^{\mathrm{t}} A_1^{\mathrm{t}} \pi(\gamma) A_0 = 0$ and 0 otherwise. The ξ_1 with this property form a subspace of $\mathbb{F}^{I'}$; it has at least one element, and at least $\#\mathbb{F}$ elements when the matrix is singular. So the sum over ξ_1 of the mean over ξ_0 of $\sum_\gamma \omega_{\xi_1, \xi_0}(\gamma)$ is the sum over γ of $\omega(\gamma)$ times the number of elements of this subspace. It is a real number, and as $\omega \geq 0$ by (a),

$$\#\mathbb{F} \cdot \sum_{\substack{\gamma \in G \\ \det(A_1^{\mathrm{t}} \pi(\gamma) A_0) = 0}} \omega(\gamma) \;\leq\; \sum_{\xi_1 \in \mathbb{F}^{I'}} (\#\mathbb{F})^{-\#I'} \sum_{\xi_0 \in \mathbb{F}^{I'}} \operatorname{Re} \sum_{\gamma \in G} \omega_{\xi_1, \xi_0}(\gamma).$$

Step 2. If ξ_1 or ξ_0 is zero, then $\omega_{\xi_1, \xi_0} = \omega$. We claim that

$$\operatorname{Re} \sum_{\gamma \in G} \omega_{\xi_1, \xi_0}(\gamma) \;\leq\; \sqrt{(\#\mathbb{F})^{\#I}} \cdot Y \qquad \text{for all non-zero } \xi_1, \xi_0 \in \mathbb{F}^{I'}. \tag{8}$$

In the inner product space $\mathbb{C}^{\mathbb{F}^I}$, with standard basis $(\mathbf{1}_\rho)_{\rho \in \mathbb{F}^I}$, put

$$\Psi_\rho \;=\; (\#\mathbb{F})^{-\#I/2} \sum_{\rho' \in \mathbb{F}^I} \Psi(-\rho \cdot \rho')\, \mathbf{1}_{\rho'} \qquad \text{for } \rho \in \mathbb{F}^I.$$

By (7) these vectors form a second orthonormal family, and

$$\langle \Psi_\rho, \mathbf{1}_{\rho'} \rangle = (\#\mathbb{F})^{-\#I/2}\, \Psi(\rho \cdot \rho') \qquad \text{for all } \rho, \rho' \in \mathbb{F}^I.$$

Consider in $\mathbb{C}^{\mathbb{F}^I} \otimes \mathcal{H}$ the two vectors

$$F = \sum_{\gamma \in G} \Psi_{(\pi(\gamma)^{\mathrm{t}})^{-1} A_1 \xi_1} \otimes v(\gamma), \qquad F' = \sum_{\gamma \in G} \mathbf{1}_{\pi(\gamma) A_0 \xi_0} \otimes v(\gamma).$$

The dot product of $(\pi(\gamma)^{\mathrm{t}})^{-1}A_1\xi_1$ and $\pi(\gamma')A_0\xi_0$ is $\xi_1 \cdot A_1^{\mathrm{t}}\pi(\gamma^{-1}\gamma')A_0\,\xi_0$. So by (b) the inner product of the term of F at γ with the term of F' at γ' is $(\#\mathbb{F})^{-\#I/2}\,\omega_{\xi_1,\xi_0}(\gamma^{-1}\gamma')$, and Lemma 6.1 gives

$$\langle F, F'\rangle \;=\; \#G \cdot (\#\mathbb{F})^{-\#I/2} \sum_{\gamma\in G} \omega_{\xi_1,\xi_0}(\gamma).$$

In the same way, the inner product of the terms of F at γ and γ' is $\omega(\gamma^{-1}\gamma')$ if $(\pi(\gamma^{-1}\gamma')^{\mathrm{t}})^{-1}A_1\xi_1 = A_1\xi_1$ and 0 otherwise, because the family (Ψ_ρ) is orthonormal and $\gamma \mapsto (\pi(\gamma)^{\mathrm{t}})^{-1}$ is a homomorphism. By Lemma 6.1 and (d), $\|F\|^2 \le \#G \cdot Y$; likewise $\|F'\|^2 \le \#G \cdot Y$. Hence $\mathrm{Re}\langle F, F'\rangle \le \|F\|\,\|F'\| \le \frac{1}{2}(\|F\|^2 + \|F'\|^2) \le \#G \cdot Y$, which is (8).

Step 3. In the right side of Step 1, the terms with $\xi_1 = 0$ contribute $\sum_\gamma \omega(\gamma)$. The terms with $\xi_1 \neq 0$ and $\xi_0 = 0$ contribute at most the same, because there are fewer than $(\#\mathbb{F})^{\#I'}$ of them and $\sum_\gamma \omega(\gamma) \ge 0$. The remaining terms contribute at most $(\#\mathbb{F})^{\#I'}\sqrt{(\#\mathbb{F})^{\#I}} \cdot Y$, by (8) and (c). This is the assertion. □

LEAN `card_mul_sum_det_le` · uses `inner_sum_sum_eq_card_mul`, and from the background library `sum_addChar_dotProduct` (the relation (7)), `invTransposeGL` and `transposeGL` (the map $\gamma \mapsto (\pi(\gamma)^{\mathrm{t}})^{-1}$)

Definition 6.3 (the dyad sum of a family)**.** Let $\mathcal{H}$ be a complex inner product space with an orthonormal basis $e = (e_{i'})_{i'\in I'}$ indexed by a finite set I', and let $v = (v_i)_{i\in I}$ be a family of vectors of $\mathcal{H}$ indexed by a finite set I. For $i \in I$ let $\bar{v}_i = (\langle v_i, e_{i'}\rangle)_{i'\in I'}$ in $\mathbb{C}^{I'}$ be the vector of the complex conjugates of the coordinates of v_i in the basis e. The *dyad sum* of v is

$$\Delta_e(v) \;=\; \sum_{i\in I} \bar{v}_i \otimes v_i \quad \text{in } \mathbb{C}^{I'} \otimes \mathcal{H}.$$

LEAN `dyadSum`

Lemma 6.4 (inner products of dyad sums)**.** *Let $\mathcal{H}$ be a complex inner product space with an orthonormal basis $e = (e_{i'})_{i'\in I'}$ indexed by a finite set I', and let $v = (v_i)_{i\in I}$ and $w = (w_{i''})_{i''\in I''}$ be families of vectors of $\mathcal{H}$ indexed by finite sets I and I''. Then*

$$\langle \Delta_e(v), \Delta_e(w)\rangle \;=\; \sum_{i\in I} \sum_{i''\in I''} |\langle w_{i''}, v_i\rangle|^2.$$

Proof. The inner product of $\bar{v}_i \otimes v_i$ and $\bar{w}_{i''} \otimes w_{i''}$ is $\langle \bar{v}_i, \bar{w}_{i''}\rangle \cdot \langle v_i, w_{i''}\rangle$, and by Parseval's identity

$$\langle \bar{v}_i, \bar{w}_{i''}\rangle \;=\; \sum_{i'\in I'} \langle w_{i''}, e_{i'}\rangle\,\langle e_{i'}, v_i\rangle \;=\; \langle w_{i''}, v_i\rangle.$$

The product of $\langle w_{i''}, v_i\rangle$ and its complex conjugate $\langle v_i, w_{i''}\rangle$ is $|\langle w_{i''}, v_i\rangle|^2$. □

LEAN `inner_dyadSum`

Under the identification of $\mathbb{C}^{I'} \otimes \mathcal{H}$ with the endomorphisms of $\mathcal{H}$ that the basis e provides, the dyad sum of v is the positive operator $F \mapsto \sum_{i\in I}\langle v_i, F\rangle\, v_i$, and the inner product of the lemma is the trace of the product of two such operators. This remark is ours and is not used.

Proposition 6.5 (a variance inequality)**.** *Let $\mathcal{H}$ be a finite-dimensional complex inner product space, $e = (e_{i'})_{i'\in I'}$ an orthonormal basis of $\mathcal{H}$ indexed by a finite set I',*

and I a finite set. Let $T\colon \mathbb{C}^I \to \mathcal{H}$ and $C\colon \mathcal{H} \to \mathcal{H}$ be $\mathbb{C}$-linear maps, $\mathcal{U} \subseteq \mathbb{C}^I$ and $\mathcal{H}' \subseteq \mathcal{H}$ linear subspaces, and $\mathcal{E}$ a real number. Suppose that $\sum_{i\in I}\|(T^*T-1)\mathbf{1}_i\| \le \mathcal{E}$, where T^* is the adjoint of T, and that $(T-CT)(\mathcal{U}) \subseteq \mathcal{H}'$. Then

$$\dim \mathcal{U} \;-\; \mathcal{E} \;-\; \sum_{i\in I}\|CT\mathbf{1}_i\|^2 \;\le\; \mathrm{Re}\langle \Delta_e(T\mathbf{1}), \Delta_e(e')\rangle,$$

where $T\mathbf{1}$ is the family $(T\mathbf{1}_i)_{i\in I}$ and e' is the orthonormal basis of $\mathcal{H}'$, indexed by $\{1,\dots,\dim \mathcal{H}'\}$, that the library provides.

By Lemma 6.4 and Parseval's identity in $\mathcal{H}'$ the right side is the real number $\sum_{i\in I}\|p_{\mathcal{H}'}T\mathbf{1}_i\|^2$, the square of the Hilbert–Schmidt norm of $p_{\mathcal{H}'}T$; it does not depend on the choice of e'. So the proposition says: if T is nearly an isometry, and if on a subspace $\mathcal{U}$ it lands in $\mathcal{H}'$ up to the small map CT, then the part of T in $\mathcal{H}'$ has Hilbert–Schmidt norm squared at least about $\dim \mathcal{U}$.

Proof. Let $v = (v_{i''})_{i''\in I''}$ be an orthonormal basis of $\mathcal{U}$, so that $\#I'' = \dim \mathcal{U}$.

Step 1. The endomorphism $p_{\mathcal{U}}(1-T^*T)$ of $\mathbb{C}^I$ maps into $\mathcal{U}$, so its trace can be computed in the basis v of $\mathcal{U}$ and also in the standard basis:

$$\dim \mathcal{U} - \sum_{i''\in I''}\|Tv_{i''}\|^2 \;=\; \sum_{i''\in I''}\langle v_{i''}, (1-T^*T)v_{i''}\rangle \;=\; \sum_{i\in I}\langle p_{\mathcal{U}}\mathbf{1}_i, (1-T^*T)\mathbf{1}_i\rangle.$$

The left side is real, and the real part of the right side is at most

$$\sum_{i\in I}\|p_{\mathcal{U}}\mathbf{1}_i\|\,\|(1-T^*T)\mathbf{1}_i\| \;\le\; \mathcal{E},$$

because $\|p_{\mathcal{U}}\mathbf{1}_i\| \le 1$. Hence $\dim \mathcal{U} - \mathcal{E} \le \sum_{i''\in I''}\|Tv_{i''}\|^2$.

Step 2. For each i'' the vector $Tv_{i''} - CTv_{i''}$ lies in $\mathcal{H}'$, so $Tv_{i''}$ and $CTv_{i''}$ have the same component orthogonal to $\mathcal{H}'$. By Pythagoras' theorem,

$$\|Tv_{i''}\|^2 \;\le\; \|p_{\mathcal{H}'}Tv_{i''}\|^2 + \|CTv_{i''}\|^2.$$

Step 3. For every $\mathbb{C}$-linear map $C'\colon \mathcal{H} \to \mathcal{H}$,

$$\sum_{i''\in I''}\|C'Tv_{i''}\|^2 = \sum_{i'\in I'}\sum_{i''\in I''}|\langle (C'T)^*e_{i'}, v_{i''}\rangle|^2 \;\le\; \sum_{i'\in I'}\|(C'T)^*e_{i'}\|^2 = \sum_{i\in I}\|C'T\mathbf{1}_i\|^2,$$

by Parseval's identity in $\mathcal{H}$, Bessel's inequality for the orthonormal family v, and Parseval's identity in $\mathbb{C}^I$.

Steps 1 and 2, and Step 3 for $C' = p_{\mathcal{H}'}$ and for $C' = C$, give

$$\dim \mathcal{U} - \mathcal{E} \;\le\; \sum_{i\in I}\|p_{\mathcal{H}'}T\mathbf{1}_i\|^2 + \sum_{i\in I}\|CT\mathbf{1}_i\|^2,$$

and the first sum is the right side of the assertion, as was said after the statement. □

LEAN `finrank_sub_le_re_inner_dyadSum` · uses `inner_dyadSum`

7 Where the results are used

The heights serve Theorem C of the argument, and the linear algebra of §§5 and 6 serves Theorem B. The notation of this section is that of the overview of the handout: D is admissible data, with third scale $b(D)$ and number of lifts $m(D)$; $\mathrm{Row}(D)$ is the space of rows; for an $m(D)$-fold twist ϑ of D, $\Theta_{D,\vartheta}\colon \mathrm{Row}(D) \to \mathcal{A}_{D,\vartheta}$ is the chain of lifts and $\mathfrak{z}_D(\vartheta) = \det(\Theta^*_{D,\vartheta}\Theta_{D,\vartheta})$. What follows was read in the statements and in the last steps of the formal proofs; the chapters named give the proofs.

Theorem C: a covolume is bounded from below. Let $y_1, \dots, y_n$ be linearly independent rows with $n \geq (1 - 4/b(D)^2)\dim \mathrm{Row}(D)$, of D-index at most δ, whose lifts at the trivial twist satisfy $\mathrm{covol}^2_\sigma(\Theta_{D,1}y_1, \dots, \Theta_{D,1}y_n) \leq \exp(V)$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$. Chapter VIII provides a family $\theta = (\theta_{\ell,\iota})$ of $m(D)$-fold twists, one for each pair in $\mathcal{J}$, that is fit for D. Two height bounds are then proved.

First bound. The family $\mathfrak{z}_D(\theta_{\ell,\iota})/\mathfrak{z}_D(1)$ has height at most

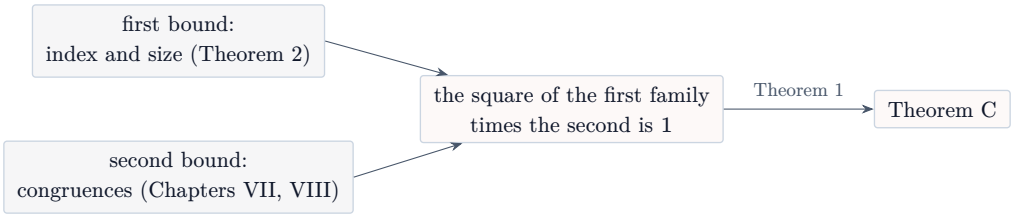
$$V + 2\delta + b(D) \cdot \dim \mathrm{Row}(D).$$

This is Theorem 2 for $W = \mathrm{Row}(D)$, for the set Ξ of the $m(D)$-fold twists with $\vartheta_0 = 1$, for $T_\vartheta = \Theta_{D,\vartheta}$, and for the sets $\mathcal{L}_{\ell,\iota}(j)$ of the j-integral forms, for which (f) is the integrality of the pairing. The basis w consists of $y_1, \dots, y_n$ and of n' further rows $z_1, \dots, z_{n'}$ given by Lemma 4.2, taken from a spanning set of crude rows that Chapter VII constructs. These come with scalars $c_{\ell,\iota}$, ratios of a twisted to an untwisted constant, for which the family $|c|^{-2}$ has a height bound. The matrix of (g) is made of two blocks: the matrix that the D-index provides for the y_i, with $|j(\det u)|_\ell \geq \exp(-\eta_\ell)$, and $c_{\ell,\iota}$ times the unit matrix for the z_i; so $\nu = n'$, and hypothesis (e) holds with the δ of the D-index. The number α is V plus a term for the z_i. There are at most $(4/b(D)^2)\dim \mathrm{Row}(D)$ vectors z_i, and the last lines of the formal proof bound what each of them adds to α and to νh by $b(D)^3/4$: this is the term $b(D) \cdot \dim \mathrm{Row}(D)$.

Second bound. The family $\mathfrak{z}_D(1)^2/\mathfrak{z}_D(\theta_{\ell,\iota})^2$ has height at most

$$2\,\dim \mathrm{Row}(D) \cdot (2 \log b(D) \cdot \mathrm{budget}(D) - h_{\mathrm{main}}(D)).$$

Here $\mathfrak{z}_D(\vartheta)$ is a constant times the product of the volumes of the $m(D)$ single lifts, each ratio of an untwisted to a twisted volume has a height bound (Chapter VII), and Proposition 3.3 and Lemma 3.1 combine them.



The square of the first family times the second is the constant family 1. By Proposition 3.3 and Theorem 1, twice the first bound plus the second is non-negative:

$$\dim \mathrm{Row}(D) \cdot (h_{\mathrm{main}}(D) - 2 \log b(D) \cdot \mathrm{budget}(D) - b(D)) \;\leq\; V + 2\delta,$$

which gives Theorem C because $b(D) \le \log b(D) \cdot \mathrm{budget}(D)$. The twist $\theta_{\ell,\iota}$ depends on the pair (ℓ, ι), so the numbers $\mathfrak{z}_D(\theta_{\ell,\iota})$ are not the conjugates of one algebraic number, and no product formula applies to them. The height carries the ℓ-adic bounds of the two families through the multiplication, and the product formula is applied at the end to the auxiliary numbers H alone. The complete deduction belongs to the note on the unit *New.Endgame*, which ends the argument.

Other height bounds. Height bounds for families of ratios of a twisted to an untwisted quantity (values of Hecke L-functions, volumes of single lifts, the constants above) are proved in the units *New.Rows*, *New.Exchange* and *New.Selmer*, and combined by Lemma 3.1 and Proposition 3.3.

Theorem B: enough forms. Theorem 3 is applied with $W = \mathrm{Row}(D)$, with U the space of columns $\mathrm{Col}(D)$, with the finite group $\mathsf{G}(D)$ as index set and with $\varepsilon = b(D)^{-2}$. The map B_γ is a fixed operator from the columns onto the ramified columns followed by the Poincaré map $\mathcal{P}_D(\gamma)$, in the normalisation of Chapter VI. That this family is $b(D)^{-2}$-spread is the filling theorem of that chapter. Its proof is a second moment over the group: Proposition 6.5 is applied to each translate and summed, with Lemmas 6.1 and 6.4, and Proposition 6.2 is applied inside an induction, to a function of positive type and to the set where a minor is singular. Theorem 3 then gives the finite set $\mathcal{T}$ of Theorem B, with $\#\mathcal{T} \cdot \dim \mathrm{Col}(D) \le 5 \dim \mathrm{Row}(D) \cdot \log(1 + b(D)^2)$ and a span of dimension at least $(1 - 4/b(D)^2) \dim \mathrm{Row}(D)$.

8 Notes on the formal text

1. *Two ways to add up the local exponents.* Definition 1.2 asks for the bound on the sums of η over the primes below n, for all large n. Lemma 3.2 assumes the bound for all finite sets of primes, and hypothesis (e) of Theorem 2 for all finite sets of natural numbers. The formal text has these three forms, and they are kept here. In the definition the formal text says that the bound holds eventually; the threshold n_0 is this statement written out.
2. *Functions defined everywhere.* The formal Lemma 3.4 includes $q = 0$, by the convention $\log 0 = 0$. Definition 1.4 is stated for arbitrary complex vector spaces, with the library's dimension; Theorem 3 uses it for finite-dimensional spaces only.
3. *Theorem 2.* The formal statement asks (f) and (g) for every homomorphism $j \colon \mathbb{C} \to \mathbb{C}_\ell$, and its proof uses two of them for each (ℓ, ι). The sets $\mathcal{L}_{\ell,\iota}(j)$ are arbitrary subsets. The formal conclusion is written with the volume factor of the library, squared, and the quotient is formed in $\mathbb{C}$. The cost 2δ comes from the two matrices of the proof, one for j_ι and one for its conjugate, and νh from the family $|c|^{-2}$, which is bounded independently. The base map T_{ϑ_0} must be injective, so that the witness Γ_{ϑ_0} is not zero.
4. *Theorem 3.* The formal statement takes W to be an inner product space; the proof does not use the inner product. It chooses an admissible set whose span is maximal for inclusion; the proof above takes the largest dimension, which amounts to the same.
5. *Proposition 6.2.* The formal statement gives the pair A as a function on the two truth values; A_1 is its value at "true" and A_0 its value at "false". The condition

in (d) is written with one formula for both, through an automorphism of $\mathrm{GL}_I(\mathbb{F})$ that is the identity for A_0 and the passage to the inverse of the transpose for A_1, a definition of the background library. The formal proof takes a character from Mathlib and the relation (7) from the background library, where it is stated for finite commutative rings; here it is proved for a field in one line.

6. *Proposition 6.5.* The basis e enters the statement only through the dyad sums, and the basis e' is the one that the library attaches to a finite-dimensional inner product space.
7. *Arguments read from the text.* The list of arguments of each declaration was made by a program from the text of the files. For some declarations of the second file it contains variables of the surrounding section whose names are bound again inside the statement (a basis, a second map on G, a field, an index set). Lean does not take them as arguments, as the dossier notes, and where such a variable is explicit the uses of the lemma in the artifact confirm it. In the accounts of this note they are matched with the bound variables of the same name.
8. *What the final theorems use.* All declarations of the unit are stated here. Whether each of them is reached from the final theorems is for the kernel-based ledger of the handout to say.
9. *Literature named by the formal text.* The file on heights calls the product formula through a norm and adelic norms changed place by place standard, and names as related work Gaudron (2006), Bombieri and Gubler (2006, ch. 1) and notes of K. Conrad. The file on determinants names Wolsey (1982) for greedy covering with a logarithmic loss, and Bost (2001) and Laurent (1994) for size against divisibility of a determinant. The references are listed below as the artifact gives them, with the state that its own list of references records; we have not compared them.

How this note was written. From the dossier of the unit: its statements in words, its structured proofs, and its imports. The program check of the dossier covered 47 leaf steps of 7 proofs, found the 18 statements at their lines and compared the quotations of the imports with the source; a second reading of the dossier by the reading agent asked for no correction. I read the files of the unit completely, statements and proofs, and compared every statement of this note with its Lean text argument by argument, in Lean's order of quantifiers. I also read: the statements of the imported declarations in the background library and the proof of Input 1; the formal proofs of Theorem C and of its two height bounds, the statement and the last lines of the proof of Theorem B, the statement of the filling theorem, and the places where the two inequalities of §6 are applied; the authors' list of references. I did not read Mathlib, and I did not run a build. Shorter than, or different from, the formal proofs: Lemma 3.4 (the formal proof is one call of automation on the prime factorisation); the bound for $\|F\|^2$ in Proposition 6.2, which the formal proof obtains from one general identity for an orthonormal family and an automorphism of the linear group; Step 1 of Proposition 6.5, which follows the same two traces; the arithmetic at the end of Theorem 3, which the formal proof leaves to automation and which is written out here. Lemma 4.1, Corollary 3.5, Remark 3.6, the examples and the diagram are mine.

Notation

ℓ a prime number

$\mathbb{Q}_\ell$, $\bar{\mathbb{Q}}_\ell$, $\mathbb{C}_\ell$ the ℓ-adic numbers, an algebraic closure, its completion

$|\cdot|_\ell$, $|\cdot|$ the absolute value with $|\ell|_\ell = 1/\ell$; the absolute value of $\mathbb{C}$

ι an isomorphism of rings from $\mathbb{C}$ to $\bar{\mathbb{Q}}_\ell$, or to a field L

$\mathcal{I}$ the set of the pairs (ℓ, ι)

σ, $\mathrm{Aut}(\mathbb{C})$ a field automorphism of $\mathbb{C}$; the group of all of them

Z, Z', Z_i families of complex numbers indexed by $\mathcal{I}$, with entries $Z_{\ell,\iota}$

h, h', h_i real numbers, bounds for heights

$\mathrm{ht}(Z) \le h$ Z has height at most h

H, α, η a witness: a non-zero complex number, a real number, a sequence $(\eta_0, \eta_1, \dots)$ of real numbers

n, n_0, n' natural numbers; a threshold; the number of added vectors

q, q_{num}, q_{den} a rational number, its numerator and denominator

ord_ℓ, Nm, $\deg H$ exponent of ℓ; norm of a field extension; degree of $\mathbb{Q}(H)$ over $\mathbb{Q}$

$\bar{h}$ in Remark 3.6: a mean of logarithms

j, $\bar{j}$, j_ι a homomorphism of rings $\mathbb{C} \to \mathbb{C}_\ell$; j after complex conjugation; ι followed by the inclusion

O_j the complex numbers with $|j(\cdot)|_\ell \le 1$

L; τ, τ_0 an algebraically closed field; injective homomorphisms of rings

Y a real number, a bound

I, I', I''; i, i', i'', i_1 finite sets; their elements (in Theorem 2 and Lemma 4.1, i and i' both run over I)

$\#I$ the number of elements

$\mathcal{H}$, $\mathcal{H}'$, $\mathcal{H}_\vartheta$ complex inner product spaces; $\mathcal{H}'$ a subspace of $\mathcal{H}$

$\langle\cdot,\cdot\rangle$, $\|\cdot\|$ inner product, conjugate-linear in the first variable; its norm

F, F', F'', F_i vectors of an inner product space

v, w families of vectors, or maps from G to $\mathcal{H}$; Tv the family (Tv_i)

$\mathrm{Gram}(v)$ the Gram matrix $(\langle v_i, v_{i'}\rangle)$

T, T_ϑ, T^* $\mathbb{C}$-linear maps into inner product spaces; the adjoint; T^*T as in §1

W, W', W_y, $W_{\mathcal{T}}$ a finite-dimensional complex vector space; subspaces

Ξ, ϑ, ϑ_0, θ a set; its elements; a family $(\theta_{\ell,\iota})$ of elements

c a family of non-zero complex numbers $c_{\ell,\iota}$

δ, ν a real number, a bound for an index; a natural number

J a finite set of natural numbers

$\mathcal{L}_{\ell,\iota}(j)$ a subset of $\mathcal{H}_{\theta_{\ell,\iota}}$

u, u', $\overline{u'}$, u^{t} matrices of complex numbers; conjugate entries; transpose

Γ_ϑ $\det \mathrm{Gram}(T_\vartheta w)$

U, Ω, B, B_γ a complex vector space; a set; a family of linear maps $U \to W$

ε, $\mathrm{Spread}_\varepsilon(B)$ a real number; B is ε-spread

$\mathcal{T}$, $\mathcal{T}'$, $\mathcal{T}''$ finite subsets of Ω

Π, rk, codim the potential, a rank, a codimension, in the proof of Theorem 3

S; y_i, z_i a spanning set; vectors

G, γ, γ' a finite group; elements of G, or of Ω

ω, ω_{ξ_1,ξ_0} a function on G; its product with character values

$\mathbb{F}$, $\mathrm{GL}_I(\mathbb{F})$, π a finite field; invertible matrices; a homomorphism $G \to \mathrm{GL}_I(\mathbb{F})$

$A = (A_1, A_0)$ a pair of matrices over $\mathbb{F}$

ξ, ξ', ξ_1, ξ_0, ρ, ρ' vectors with coordinates indexed by a finite set

Ψ, Ψ_ρ a non-trivial additive character of $\mathbb{F}$; the normalised characters of $\mathbb{F}^I$

$\mathbf{1}$, $\mathbf{1}_i$ the standard basis of $\mathbb{C}^I$

e, e' orthonormal bases of $\mathcal{H}$ and of $\mathcal{H}'$

$\Delta_e(v)$, $\bar{v}_i$ the dyad sum; conjugate coordinates

C, C', $\mathcal{U}$, $\mathcal{E}$ linear maps $\mathcal{H} \to \mathcal{H}$; a subspace of $\mathbb{C}^I$; a real number, a bound

$p_{\mathcal{U}}$, $p_{\mathcal{H}'}$ orthogonal projections

D, $b(D)$, $m(D)$, V in §7: admissible data, its third scale, its number of lifts; a real number

$\mathrm{Row}(D)$, $\mathrm{Col}(D)$, $\mathsf{G}(D)$ rows, columns, the finite group of the data

$\Theta_{D,\vartheta}$, $\mathcal{A}_{D,\vartheta}$, $\mathfrak{z}_D(\vartheta)$ the chain of lifts, its target, $\det(\Theta^*_{D,\vartheta}\Theta_{D,\vartheta})$

$\mathcal{P}_D(\gamma)$ the Poincaré map translated by γ

covol_σ in §7: the covolume at σ, as in the overview of the handout

$\mathrm{budget}(D)$, $h_{\mathrm{main}}(D)$ the budget and the main amount of the data

READBACK NOTE 21

The seesaw identity for the chain of theta lifts

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The rows of Theorem A of the write-up are Poincaré series on an indefinite unitary group of rank r, and the forms whose size and divisibility must be controlled are their images under a chain of m theta lifts through hermitian spaces of growing rank, the last of them definite. This note proves the identity that makes that control possible: up to one non-zero constant, the chain of lifts of the Poincaré series of a ramified column is a finite combination of chains of m theta lifts of the column itself between *definite* spaces, restricted at the end, and the coefficients of the combination have denominators only at the conductor of the twist. The proof unfolds the Poincaré series and then one lift at a time against Bessel periods; each unfolded period is a finite sum over cosets whose weights are reciprocals of numbers dividing a power of the norm of the conductor.

What this note is. The artifact grh-compact is a body of Lean code whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. Its authors report that it compiles and that Lean's kernel accepts these theorems from the three standard axioms; the record of checks of the write-up says who replayed what. That is a fact about a formal text: no mathematician has read the argument through, and the result is a *claim*. This note is one of four notes of the unit *Seesaw* (Chapter V, Theorem A: short forms) and treats 80 of its 312 declarations: the indefinite chain of lifts, the stage functions of its unfolding, the lattice estimates and the identity itself. The proofs of this note's own declarations are written out; the statements taken from other units, from the other three notes of the unit and from the background library are marked as *Inputs*, with their owners. Every statement was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 80 declarations.

1 The statement

Setting 1.1 (the data)**.** Let $P = (N_0, d)$ be parameters and D admissible data for P (Chapter III of the write-up). The components of the record D are written with bare letters: the scales x, x_1, b, the exponent μ, the number of lifts m, the rank r, the thick set, the primes $g_0 \neq g_1$ and the integer π_g of $K = \mathbb{Q}(\sqrt{-d})$ with $\pi_g\overline{\pi_g} = g_0 g_1$. Everything else attached to D is written as a function of D:

(a) from Chapter III: the CM field $E(D)$ with its CM type, the set of its infinite places, and its Weil data (an element $\mathbf{j}$ with $\bar{\mathbf{j}} = -\mathbf{j}$, a finite idele α and the splitting character v); the number $f(D)$ of infinite places; the product $g(D) = g_0 g_1$; $t(D) = 5r$; the ranks $n_j(D)$, with $n_0(D) = r + 1 - m$;

(b) from the note *The characters, the level prime and the index sets of the data* of this unit: the number $\varrho(D)$, for which $m = 2\varrho(D) + 2$; the integer $\bar{\pi}_g(D)$

of $E(D)$, the conjugate of π_g, whose prime divisors are the *chosen places*; the level prime $N(D)$, which splits completely in $E(D)$ and is prime to $g(D)$, and an integer $\pi_N(D)$ of $E(D)$ with $\pi_N(D)\,\overline{\pi_N(D)} = N(D)$; *tame characters* ϑ of D, each with its finite set $Q(\vartheta)$ of places and its tame part ψ_ϑ, the number $\mathrm{n}(\vartheta) = \prod_{w\in Q(\vartheta)} \mathrm{N}\, w$, and the *twists* of D, the tame characters with $\psi_{\vartheta,w} \neq 1$ for all $w \in Q(\vartheta)$; the characters $\mu_{D,j}(\vartheta)$ of the norm-one adeles and their tame parts $\psi_{D,j}(\vartheta)$; the index sets $\underline{X}_j(D)$ and $\underline{Y}_j(D)$, where $\underline{Y}_j(D)$ is $\underline{Y}_0(D)$ followed by j blocks of $t(D)$ indices; the finite group $\mathsf{G}(D) = \prod \mathrm{GL}_{\underline{Y}_0(D)}(\mathbb{F}_w)$, the product over the chosen places w, and the element $e_0(D)$ of its group algebra;

(c) from the unit *Trace* (Chapter VII): for every j a hermitian space with frame $Y_j(D)$ on the index set $\underline{Y}_j(D)$ (Definition 2.1), of rank $r + j\,t(D)$, which for $j \geq m$ is the standard definite space; the space of forms of principal level on $Y_0(D)$ with its representation of $\mathsf{G}(D)$ (Definition 2.5);

(d) from the units *Columns* and *Exchange* (Chapters V and VII): the set $\Pi(D)$ of the places of $E(D)$ that divide $\pi_N(D)$; the standard definite spaces $X_j(D)$ on $\underline{X}_j(D)$, the columns $\mathrm{Col}(D)$ and the ramified columns $\mathrm{Col}^{\mathrm{ram}}(D)$, the definite chains and the maps $B^{\Psi}_{D,\vartheta}$ (Definitions 2.13 and 2.15);

(e) from the unit *Filling* (Chapter VI): the Poincaré series P_D (Definition 2.11).

The left side of the identity is *indefinite*: $\iota_{D,\vartheta}$ is the composite of m theta lifts $Y_0(D) \to Y_1(D) \to \ldots \to Y_m(D)$, the j-th formed with the character of the j-th power of ϑ, applied to forms of principal level on the indefinite space $Y_0(D)$ (Definition 2.8). The right side is *definite*: $B^{\Psi}_{D,\vartheta}$ is a finite combination, with coefficients Ψ, of composites of m theta lifts $X_0(D) \to \ldots \to X_m(D)$ of algebraic modular forms, followed by the restriction from $X_m(D)$ to $Y_m(D)$ (Definition 2.15).

Theorem A (the seesaw identity). In Setting 1.1 there is one non-zero complex number c_D, depending only on D, such that for every twist ϑ of D there is a finitely supported function $\Psi\colon \mathrm{Tr}(D) \to \mathbb{C}$ which is a good datum for ϑ (Definition 2.15) and satisfies

$$\iota_{D,\vartheta}(\mathrm{P}_D(c_D\,\varphi)) \;=\; B^{\Psi}_{D,\vartheta}(\varphi) \qquad \text{for every ramified column } \varphi \in \mathrm{Col}^{\mathrm{ram}}(D).$$

The constant c_D is chosen before ϑ, and Ψ before φ: one scalar for the datum D, one good datum for each twist, and the identity for all ramified columns at once; no condition is put on the column.

LEAN `Data.seesaw`

The proof has two engines. The first is an induction over the lifts. Its statement is abstract on purpose: the map S below will be specialised, in the proof of Theorem A, to a tensor of finite theta data.

Theorem B (unfolding). In Setting 1.1 let j be a natural number with $j \le 2\varrho(D)+2$, let $\mathcal{Y}$ be a grading of $Y_j(D)$ with norm $N(D)$, with a finite set X and a string of length l, where $l = 2\varrho(D)+1-j$ (and $l=0$ for $j = 2\varrho(D)+2$), and let a be a complex function of the tuples $\xi = (\xi_i)_{i\in\mathbb{N}}$ of real points $\xi_i \in G_\infty(Y_i(D))$. There is a complex number C such that for every tame character ϑ of D, every complex vector space M and every map S from the tuples $q = (q_i)_{i\in\mathbb{N}}$ of cosets $q_i \in G_f(Y_i(D))/\mathcal{J}_i(D,\vartheta)$ to M there is a vector $\mathsf{w} \in M$ such that:

(i) $\mathsf{w} \in \mathrm{Adm}(v_S, \mathrm{all}; \mathrm{n}(\vartheta), 1; Q(\vartheta)=\emptyset, \mathrm{cut}(D)^{\,j})$, where v_S sends a tuple $y=(y_i)$ of finite points $y_i \in K^{(\mathrm{n}(\vartheta))}(Y_i(D))$, integral at the places not dividing $\mathrm{n}(\vartheta)$, to $S\big((y_i\,\mathcal{J}_i(D,\vartheta))_i\big)$, and "all" is the set of all such tuples;

(ii) $\Omega(\mathsf{w}) = \mathsf{w}$ for every tuple $b=(b_i)$ with $b_i \in K_i^{\mathrm{col}}(D)$ and every linear map $\Omega\colon M\to M$ such that $\Omega(S(q)) = S(q')$ for all q, where $q_i' = i_{y_i(D),f}(b_i)\,q_i$ for $i<j$ and $q_i' = q_i$ for $i\ge j$;

(iii) for every form z on $Y_j(D)$ of the conjugate type $\overline{\mathcal{F}_j(D)}$, every ramified column $\varphi \in \mathrm{Col}^{\mathrm{ram}}(D)$ and every linear form $L\colon M\to\mathbb{C}$: *if* for all tuples ξ of real points and y of finite points with $y_{2\varrho(D)+2}=1$ and $y_0 \in K_D^{\mathrm{ch}}(Y_0(D))$ the function $F = \mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi,y;\mathcal{Y}]\cdot z$, in case it is integrable on $\Gamma_B(\mathcal{Y})\backslash G(Y_j(D))$, satisfies

$$\int_{\Gamma_B(\mathcal{Y})\backslash G(Y_j(D))} F \;=\; \mathsf{a}(\xi)\cdot L\big(S((y_i\,\mathcal{J}_i(D,\vartheta))_i)\big),$$

then

$$\int_{[G(Y_j(D))]} z\cdot\mathcal{L}^{(j)}(D,\vartheta)(\mathrm{P}_D\varphi) \;=\; C\cdot L(\mathsf{w}).$$

The notation $\mathrm{Adm}(\cdot,\cdot;\cdot,\cdot;\cdot,\cdot)$ for admissible combinations is recalled in Definition 2.12, the number $\mathrm{cut}(D)$ in Definition 2.17.

LEAN `Data.exists_isAdmissibleComb_unfolding`

The second engine cuts one period into a finite sum; the induction of Theorem B uses it once at every lift.

Theorem C (finite cuts). In Setting 1.1 let j be a natural number with $j \le 2\varrho(D)+1$, and let $\mathcal{Y} = \mathcal{Y}_j(D)$ be the grading of $Y_j(D)$ (Definition 2.6). There is a level A of $Y_j(D)$ with $i_{\mathcal{Y},f}(K_j^{\mathrm{col}}(D)) \subseteq A$ such that for every tame character ϑ of D there is a finite set T of cosets of $\mathcal{J}_j(D,\vartheta)$ in the finite adelic group of $Y_j(D)$ with these properties:

(i) for every $p \in B_f(\mathcal{Y}) \cap A$ and every coset t: $t \in T$ if and only if $p\,t \in T$;

(ii) if the coset of a finite point h lies in T, then h is integral at every place not dividing $\mathrm{n}(\vartheta)$, and for $j = 0$ it lies in the principal level $K_D^{\mathrm{ch}}(Y_0(D))$ at the chosen places;

(iii) let h be a finite adelic point whose coset lies in T, or for which there are a ramified column $\varphi \in \mathrm{Col}^{\mathrm{ram}}(D)$, tuples ξ, y of real and of finite points with $y_0 \in K_D^{\mathrm{ch}}(Y_0(D))$ and a real point g_∞ with $\mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}](g_\infty, h) \neq 0$; then the multiplicity $\mathrm{mult}_{B_f(\mathcal{Y}),A}(T; h\,\mathcal{J}_j(D,\vartheta))$ of Definition 2.20 divides a power of $\mathrm{n}(\vartheta)$.

Here $K_j^{\mathrm{col}}(D)$ is the level of stage j (Definition 2.13), $\mathcal{J}_j(D,\vartheta)$ the level of Definition 2.7, and $\mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}]$ the stage function of Definition 2.16.

LEAN `Data.exists_stage_cut`

2 The setting

Conventions. E is a CM field with a CM type, with complex conjugation $z \mapsto \overline{z}$; where theta functions occur, Weil data for E are fixed, and where integral Witt theory is used E is stably unramified. The letters I, I', X, X' and the letter H for an abstract group denote ambient objects: finite index sets and a group. A hermitian space with frame V over E has an index set and signs; a grading $\mathcal{Y}$ of V has a norm N, a finite set X and a string of length l; a second hermitian space with frame is V', with a grading $\mathcal{Y}'$ whose string has length l'. P denotes parameters and D admissible data for P; a tame character of D is ϑ. A commutative ring is R; index sets of blocks are R_0 and T_0. Measures are Haar measures or the measures they induce; a measurable group carries a left invariant measure. Matrices act on column vectors; g^* is the conjugate transpose of a matrix g. All statements about filling data concern filling data S of a shape, with a parameter, weights and a central element, as in Setting 2.10.

Hermitian spaces, their groups and levels. The following vocabulary belongs to the background library of the artifact; it is recalled here in the form in which this note uses it.

Definition 2.1 (spaces with frame; recalled from the background library)**.** Let $\mathbb{A}$ be the ring of adeles of E, $\mathbb{A}_f$ the ring of finite adeles and $\hat{\mathcal{O}}$ its subring of integral elements. A *hermitian space with frame* V over E consists of a finite index set I, signs $\mathrm{sgn}_V \colon I \to \{\pm 1\}$, an invertible hermitian matrix $J_V \in \mathrm{GL}_I(E)$, the Gram matrix of the basis of V, and a *frame* $x_V \in \mathrm{GL}_I(\mathbb{A})$ with $x_V^* J_V x_V$ equal to the diagonal matrix of the signs at every infinite place and to the identity at the finite places. Its finite part is $x_{V,f} \in \mathrm{GL}_I(\mathbb{A}_f)$, and $x_{V,f}\hat{\mathcal{O}}^I$ is the *lattice* of V; it is unimodular. The groups of V are written in the coordinates of the frame: $G_f(V) = \{g \in \mathrm{GL}_I(\mathbb{A}_f) : g^* g = 1\}$,

the product $G_\infty(V)$ over the infinite places of the unitary groups of the signs, and $G(V) = G_\infty(V) \times G_f(V)$; a finite point g is identified with $(1, g)$. In *rational coordinates* a point g is the matrix $x_V g x_V^{-1}$, which preserves J_V, and the *rational points* $\Gamma(V)$ are the g for which it has entries in E. The quotient $[G(V)] = \Gamma(V)\backslash G(V)$ carries the invariant measure fixed in the library, and for a subgroup Δ of $\Gamma(V)$ the quotient $\Delta\backslash G(V)$ carries the measure induced by the same Haar measure. V is *standard* if all signs are 1 and $x_V = 1$. The subgroup $K_0(V) = G_f(V) \cap \mathrm{GL}_I(\hat{\mathcal{O}})$ is the stabiliser of the lattice, and a *level* of V is an open subgroup of $G_f(V)$ contained in $K_0(V)$. For a finite place w, $K_w(V)$ is the subgroup of the elements of $K_0(V)$ that are 1 at all places other than w and $\overline{w}$. For a natural number n, $K^{(n)}(V)$ is the subgroup of the finite points whose component at w is integral with integral inverse for every finite place w not dividing n. For a finite idele β and a finite place w, $\mathrm{ord}_w\,\beta$ is the order of the component of β at w.

Definition 2.2 (gradings and Bessel groups; recalled from the background library)**.** Let V be a hermitian space with frame, with index set I, let $N \in E$ with $N \neq 0$ and $\overline{N} = N$, let X be a finite set and $l \geq 0$ an integer. A *grading* $\mathcal{Y}$ of V as X *plus a string of length* l *with norm* N consists of a bijection $e_{\mathcal{Y}} \colon X \sqcup \{0, \dots, l-1\} \to I$ and a constant $\mathfrak{c}(\mathcal{Y}) \in E$ with $\mathfrak{c}(\mathcal{Y}) \neq 0$ and $\overline{\mathfrak{c}(\mathcal{Y})} = \mathfrak{c}(\mathcal{Y})$, such that in the basis indexed through $e_{\mathcal{Y}}$ the Gram matrix J_V is the identity on X, pairs the string vectors z_a and $z_{a'}$ to 1 if $a + a' = l - 1$ and $a \neq a'$, to $-N$ if $a = a'$ and $2a = l - 1$, and to 0 otherwise, and pairs X with the string to 0. The *grade* of a basis vector is 0 on X and $\mathrm{gr}(z_a) = l - 1 - 2a$ on the string; z_{l-1-a} is the *reverse* of z_a. With matrices in rational coordinates:

- the *unipotent subgroup* $U(\mathcal{Y})$ of $G(V)$ consists of the points u for which $u - 1$ strictly raises grades;
- $i_{\mathcal{Y}} \colon G(X) \to G(V)$ is the inclusion of the group of the standard definite space on X, acting on the span of X and fixing the string vectors, and $i_{\mathcal{Y},f}$ is its finite part;
- the *Bessel group* $B(\mathcal{Y})$ consists of the points that fix every string vector of grade ≥ 0 up to vectors of strictly higher grade; it contains $U(\mathcal{Y})$ and the image of $i_{\mathcal{Y}}$. Its finite part is $B_f(\mathcal{Y}) = \{g \in G_f(V) : (1, g) \in B(\mathcal{Y})\}$, its rational points are $\Gamma_B(\mathcal{Y}) = \Gamma(V) \cap B(\mathcal{Y})$, and $[B(\mathcal{Y})]$ is the quotient of $B(\mathcal{Y})$ by $\Gamma_B(\mathcal{Y})$, with the finite measure induced by a Haar measure.

A function $F \colon G(V) \to \mathbb{C}$ is *generic for* $\mathcal{Y}$ if it is continuous, left invariant under $\Gamma_B(\mathcal{Y})$, and for every $u \in U(\mathcal{Y})$ such that $u - 1$ raises grades by at least 2 and every $g \in G(V)$ satisfies $F(ug) = \psi_E(\frac{\mathrm{j}}{2}\,\mathrm{tr}(\mathrm{sh}_{\mathcal{Y}}\,u))F(g)$; here ψ_E is the standard additive character of $\mathbb{A}/E$ and $\mathrm{sh}_{\mathcal{Y}}$ is the rational matrix that kills X and sends z_a to a multiple of z_{a+1} (and the last string vector to 0), the multiple being $\mathfrak{c}(\mathcal{Y})$ times $-N$ if z_a is the middle vector, times $-N\mathfrak{c}(\mathcal{Y})$ if l is even and z_a has grade 1, and times 1 otherwise.

Definition 2.3 (theta data, lifts and the unfolding step; recalled)**.** For hermitian spaces with frame V and V' the space $\mathrm{Hom}(V, V')$ is a hermitian space with frame. For a hermitian space with frame W the library provides the space $\mathcal{S}(W)$ of theta data with the Heisenberg operators $\varrho(y)$ of the adelic vectors y (and $\varrho_f(y)$ of the finite ones), the Weil representation ω of $G(W)$, the theta functional θ, the vacuum, the *finite part*

$\mathcal{W}_f(W)$ spanned by the translates $\varrho_f(y)$ of the vacuum, and the datum $v \otimes f$ made of a vector v of the Fock model at the infinite places and $f \in \mathcal{S}(W)$. For a character ν of the norm-one adeles the pair $G(V) \times G(V')$ acts on $\mathcal{S}(\mathrm{Hom}(V,V'))$ by the Weil representation twisted by ν and powers of v, the *twisted pair action* ω_ν^{pr} of the note *Two consecutive theta lifts*; its restriction to finite points acts on the finite part. The *theta lift* with datum Φ of a function F on $[G(V)]$ is $h \mapsto \int_{[G(V)]} \theta(\omega_\nu^{\mathrm{pr}}(g,h)\Phi)\, F(g)\, dg$. Let $\mathcal{Y}$, $\mathcal{Y}'$ be gradings of V, V' with the same norm and strings of lengths l and $l-1$. The *string map* $T_{\mathcal{Y},\mathcal{Y}'} \colon V \to V'$ is the rational matrix that kills X and sends the string vector z_a of $\mathcal{Y}$ to a multiple of the string vector of $\mathcal{Y}'$ with the same number a (and the last one to 0); the multiple is 1, $-N\mathfrak{c}(\mathcal{Y})$ or $\mathfrak{c}(\mathcal{Y})$ for z_a of positive, zero or negative grade if l is odd, and $\mathfrak{c}(\mathcal{Y})$ or 1 for positive or negative grade if l is even. A matrix $n \colon V \to V'$ is read as a vector of $\mathrm{Hom}(V,V')$ in the coordinates of the frames, and the *degree* of its position (i',i) is $\mathrm{gr}(i') - \mathrm{gr}(i)$. For $g \in G(V)$, $h \in G(V')$ the *constant term at the string map* $\mathrm{ct}_{\mathcal{Y},\mathcal{Y}'}(\nu,\Phi)(g,h)$ is the mean of

$$\theta\big(\varrho(n)\,\varrho(T_{\mathcal{Y},\mathcal{Y}'})\,\omega_\nu^{\mathrm{pr}}(g,h)\Phi\big)$$

over the adelic matrices $n \colon V \to V'$ with entries only in positions of positive degree, modulo the rational ones. For a function F on $G(V)$ and $x \in G(V)$ the *unfolded function* is

$$\big(\mathrm{unf}_{\mathcal{Y},\mathcal{Y}'}(\nu,\Phi;F,x)\big)(h) = \int_{[B(\mathcal{Y})]} F(\varsigma x)\ \mathrm{ct}_{\mathcal{Y},\mathcal{Y}'}(\nu,\Phi)(\varsigma x,h)\, d\varsigma.$$

Inputs 1 (the background library). In the notation of Definitions 2.2 and 2.3:

(a) *Genericity is inherited.* If F is generic for $\mathcal{Y}$ and $\mathfrak{c}(\mathcal{Y}') = \mathfrak{c}(\mathcal{Y})$, then $\mathrm{unf}_{\mathcal{Y},\mathcal{Y}'}(\nu,\Phi;F,x)$ is generic for $\mathcal{Y}'$.

(b) *One unfolding step.* If F is generic for $\mathcal{Y}$ and z is an automorphic, rapidly decreasing function on $G(V')$, then $\mathrm{unf}_{\mathcal{Y},\mathcal{Y}'}(\nu,\Phi;F,x)\cdot z$ is integrable on $\Gamma_B(\mathcal{Y}')\backslash G(V')$, and its integral there equals $\int_{[B(\mathcal{Y})]} F(\varsigma x) \int_{[G(V')]} \theta(\omega_\nu^{\mathrm{pr}}(\varsigma x,h)\Phi)\, z(h)\, dh\, d\varsigma$.

(c) *Lift and descent are transposes.* A datum Φ is an *arrow* from a type q on V to a type q' on V' if every form of type q is rapidly decreasing and its theta lift with datum Φ is a form of type q'. If Φ is an arrow from q to q' and, for the pair with the two groups exchanged, an arrow from $\overline{\mathsf{q}'}$ to $\overline{\mathsf{q}}$, then for a form F of type q and a form z of type $\overline{\mathsf{q}'}$ the integral over $[G(V')]$ of z times the lift of F equals the integral over $[G(V)]$ of F times the lift of z for the exchanged pair (the *descent* of z).

(d) *Adapted bases exist* (Hermite reduction over $\hat{\mathcal{O}}$), *and Witt's theorem holds over* $\hat{\mathcal{O}}$: if E is stably unramified and two matrices over $\hat{\mathcal{O}}$ with n rows and equally many columns have left inverses over $\hat{\mathcal{O}}$ and equal Gram matrices for the standard form, then a matrix in $\mathrm{GL}_n(\hat{\mathcal{O}})$ preserving the standard form carries one to the other.

Inputs 1, continued (the background library). In the same notation:

(e) *Discrete-series edges are arrows.* If the parameters, weights and signs of V and V' correspond in the sense of the unit *Exchange*, then the vector of the Fock model given by the product of the chosen joint harmonic polynomials is an *edge* between the two discrete-series types; and an edge, tensored with any element of the finite part, is an arrow in the sense of (c) from the first type to the second and, for the pair with the two groups exchanged, from the conjugate of the second to the conjugate of the first, for characters of the weights of the two spaces.

(f) *Data named modulo a modulus.* For a modulus $\mathfrak{m}$, integral finite points $k \in K_0(V)$, $k' \in K_0(V')$ and a residue matrix y modulo $\mathfrak{m}$, with $y' = \overline{k'}^{-1} y\, \overline{k}$ for the reductions $\overline{k}$, $\overline{k'}$ modulo $\mathfrak{m}$: the operator $\omega_\nu^{\mathrm{pr}}((1,k),(1,k'))$ carries the vector named on the vacuum by the indicator of y' to the vector named by the indicator of y, times the value of the twisting character of V at $\det k'$ and the inverse of the value of that of V' at $\det k$.

(g) *Constant terms are zero terms.* There is a splitting of $\mathrm{Hom}(V,V')$, in the sense of the note *Two consecutive theta lifts*, whose isotropic frame consists of the basis vectors at the positions of positive degree, such that for every datum Φ and every adelic matrix $y\colon V \to V'$ the mean of $\theta(\varrho(n)\varrho(y)\Phi)$ over the matrices n of positive degree, as in Definition 2.3, is the theta function of the zero term of $\varrho(y)\Phi$ along that splitting.

(h) *Kernels of definite pairs give theta lifts.* For standard definite spaces of ranks $0 < n < n'$, weights that fit, a level, a non-zero scale and characters of the two weights, the lifts of algebraic modular forms by the theta kernels of the pair form a family of theta lifts in the sense of Input 5 of the note *Two consecutive theta lifts*: the theta integral of a coefficient of a form against a datum with a polynomial vector at the infinite places is a coefficient of the lift of the form.

(i) *Cut-off functions and integration in stages.* A proper action of a group with a right invariant measure on a σ-compact Hausdorff space has a cut-off function, a non-negative function whose integral over every orbit is 1. If Δ is a subgroup of a subgroup H of a group G, and a map $(x,h) \mapsto h\,\mathsf{s}(x)$ carries the product of a measure on a space of parameters x and the measure of H to the measure of G, then for a measurable, left Δ-invariant function F that is integrable on $\Delta\backslash G$, the inner integrals $\int_{\Delta\backslash H} F(h\,\mathsf{s}(x))\,dh$ are integrable in x and their integral is $\int_{\Delta\backslash G} F$; the quotients carry the measures induced as in Definition 2.1.

Status of Inputs 1. For (a) and (b) the Lean file cites B. Wang Peng Jun, *Global theta lifting and automorphic periods associated to nilpotent orbits*, J. Number Theory 271 (2025), Prop. 3.2 and Thm. 4.5, and for the local case R. Gomez and C.-B. Zhu, GAFA 24 (2014); the authors mark the first as compared, with the place confirmed. Our catalogue has not confirmed these places: *reference to be confirmed.* For (d) the catalogue lists Witt's theorem over $\hat{\mathcal{O}}$ in the special case of orthonormal columns, which the library deduces from the statement with equal Gram matrices used here,

and gives for it U. A. First, *Witt's extension theorem for quadratic spaces over semiperfect rings*, Remark 2.1 and Corollary 4.9, applied on each orbit of conjugation on the finite places; for Hermite reduction it records "Hermite normal form over a valuation ring" without a place. For the first statement of (e) the catalogue cites Ichino, *Theta lifting for discrete series representations of real unitary groups* (arXiv:2002.09148), Theorem 4.1 and Lemma 7.8, pp. 35–36, for the compact types, and records the verdict of its second reading: the formal matching condition selects witnesses for a two-sided analytic statement beyond the published joint-type criterion. So the formal statement is not a special case or a weaker form of the cited ones: it goes beyond them, and its relation to the literature is unresolved; it is used here as the library proves it. Statement (c), the second statement of (e) and (f) are classed elementary. For (h) the library's heading is "Theta lift for a definite unitary pair as a class sum on algebraic modular forms"; for the class-sum formula behind it the catalogue names B. Gross, *Algebraic modular forms*, Israel J. Math. 113 (1999), Kashiwara–Vergne (1978) and R. Howe, *Transcending classical invariant theory*, J. Amer. Math. Soc. 2 (1989), place not confirmed. For (g) and (i) the catalogue has no entry: *reference to be confirmed.*

The data.

Definition 2.4 (index sets and blocks)**.** In Setting 1.1, for a natural number j the map $\mathrm{in}_{D,j}\colon \underline{Y}_j(D) \to \underline{Y}_{j+1}(D)$ is the inclusion of the index set of $Y_j(D)$ as the first summand of $\underline{Y}_{j+1}(D) = \underline{Y}_j(D) \sqcup \{0, \dots, t(D)-1\}$. Every $\underline{Y}_j(D)$ is non-empty. For sets R_0 and T_0 and a natural number j, let R_0 followed by j copies of T_0 be the disjoint union built by adding one copy of T_0 at a time; for an index i of it the *block number* $\mathrm{bl}_j(i) \in \{0, \dots, j\}$ is 0 if i lies in R_0 and ν if i lies in the ν-th copy of T_0. A square matrix indexed by such a set is *block upper triangular* if its entry at (i, i') vanishes whenever $\mathrm{bl}_j(i) > \mathrm{bl}_j(i')$, and for $\nu \in \{0, \dots, j\}$ its ν-th *diagonal block* is the square submatrix on the indices of block number ν.

LEAN `Data.inclY` · `Data.instNonemptyY` · `blockNumber`

Definition 2.5 (forms of principal level; recalled from the unit *Trace*)**.** In Setting 1.1, for a hermitian space with frame V over $E(D)$, $K_D^{\mathrm{ch}}(V)$ is the level of the elements of $K_0(V)$ that are congruent to 1 modulo every chosen place, the *principal level at the chosen places*. The forms on $Y_0(D)$ of the type of the rows that are fixed by $K_D^{\mathrm{ch}}(Y_0(D))$ are the *forms of principal level*; the group $\mathsf{G}(D)$ acts on them through the reductions of $K_0(Y_0(D))$ at the chosen places, a form F being sent by $\gamma \in \mathsf{G}(D)$ to γF.

Definition 2.6 (the gradings of the spaces $Y_j(D)$)**.** In Setting 1.1:

(a) for a natural number j with $j \le 2\varrho(D)+1$, $\mathcal{Y}_j(D)$ is the grading of $Y_j(D)$ as $\underline{X}_j(D)$ plus a string of length $2\varrho(D)+1-j = m-1-j$ with norm $N(D)$, with the bijection onto $\underline{Y}_j(D)$ fixed in the unit *Trace* and with the constant $\mathfrak{c}(\mathcal{Y}_j(D)) = -\left(\mathbf{j}\, g(D)\, \varpi(P,\mu)\right)^{-1}$, where $\varpi(P,\mu)$ is the generator of the different of $E(D)$ fixed in Chapter III;

(b) $\mathcal{Y}_{\mathrm{last}}(D)$ is the grading of the standard space $Y_m(D)$ as a set of $n_m(D)-1$ elements, the set $\underline{X}_m(D)$ without its last element, plus a string of length 0, with

norm $N(D)$ and constant 1. In the formal text it is given for every number M together with a proof that $m = M$.

The last element of $\underline{X}_j(D)$ is called the *point* of $\underline{X}_j(D)$, and $\underline{X}_j^\circ(D)$ is the set $\underline{X}_j(D)$ without its point.

LEAN `Data.gradingY` · `Data.lastGrading`

For $j \le m-1$ the space $Y_j(D)$ is thus the orthogonal sum of the definite space $X_j(D)$ and a string of length $m-1-j$, one vector shorter after each lift. A non-empty string makes the space indefinite (by its hyperbolic planes and, for odd length, its middle vector of norm $-N(D)$). For $j = m-1$ the string is empty and $Y_{m-1}(D)$ is definite; $Y_m(D)$ is the standard definite space of rank $n_m(D) - 1$, whose index set the grading $\mathcal{Y}_{\mathrm{last}}(D)$ identifies with $\underline{X}_m^\circ(D)$.

Definition 2.7 (one lift of the indefinite chain)**.** In Setting 1.1 let ϑ be a tame character of D and j a natural number.

(a) $\mathcal{J}_j(D,\vartheta)$ is the level of $Y_j(D)$ of the elements of $K_0(Y_j(D))$ that are congruent to 1 modulo every chosen place and modulo every place of $Q(\vartheta)$.

(b) $\psi_j^{\uparrow}(D,\vartheta) = \psi_{D,j+1}(\vartheta^{j+1})$ is the tame part of the character $\mu_{D,j+1}(\vartheta^{j+1})$ of the lift number $j+1$: a family of characters of the residue fields, equal to $\omega_{D,w}^{j+1}\psi_{\vartheta,w}^{j+1}$ at w.

(c) $\mathcal{K}_j(D,\vartheta)$ is the theta kernel of the pair $(Y_j(D), Y_{j+1}(D))$: the space of theta data of the space of homomorphisms from $Y_j(D)$ to $Y_{j+1}(D)$, with the twisted pair action ω_ν^{pr} of Definition 2.3 for $\nu = \mu_{D,j+1}(\vartheta^{j+1})$ and with the theta functional.

(d) $\Upsilon_j(D,\vartheta)$ is the element of the finite part of this space obtained from the vacuum by the operator named by the indicator function of the matrices that are integral and congruent to the block inclusion matrix of $\mathrm{in}_{D,j}$ modulo the product of the chosen places and of the places of $Q(\vartheta)$.

(e) $\mathcal{F}_j(D)$ is the space of the forms on $Y_j(D)$ of the type given by the parameter of $Y_j(D)$ fixed in the unit *Exchange*, with the Petersson product; $\overline{\mathcal{F}_j(D)}$ is the space of the forms of the conjugate type.

(f) $\mathfrak{d}_j(D,\vartheta)$ is the datum $v \otimes \Upsilon_j(D,\vartheta)$, where v is the vector of the Fock model given by the joint harmonic polynomial of the pair fixed in the unit *Exchange*.

(g) For $F \in \mathcal{F}_j(D)$, $\mathcal{L}_j(D,\vartheta)(F) \in \mathcal{F}_{j+1}(D)$ is $[K_0(Y_j(D)) : \mathcal{J}_j(D,\vartheta)]$ times the theta lift of F with the kernel $\mathcal{K}_j(D,\vartheta)$ and the datum $\mathfrak{d}_j(D,\vartheta)$ (the lift as a map between spaces of forms, as chosen in the library).

LEAN `Data.levelY` · `Data.liftTame` · `Data.thetaKernelY` · `Data.upsilonY` · `Data.FormY` · `Data.datumY` · `Data.liftY`

Definition 2.8 (the chain of lifts)**.** In Setting 1.1 let ϑ be a tame character of D. For a natural number j and a form F of principal level on $Y_0(D)$,

$$\mathcal{L}^{(j)}(D,\vartheta)(F) \;=\; \mathcal{L}_{j-1}(D,\vartheta)(\cdots \mathcal{L}_0(D,\vartheta)(F)\cdots) \in \mathcal{F}_j(D)$$

is the composite of the first j lifts. The space $Y_m(D)$ is definite and standard, and its forms of the type of $\mathcal{F}_m(D)$ are identified with algebraic modular forms on $Y_m(D)$; $\iota_{D,\vartheta}$ is the linear map that sends a form F of principal level on $Y_0(D)$ to the algebraic modular form that corresponds to $\mathcal{L}^{(m)}(D,\vartheta)(F)$.

LEAN Data.liftChainY · Data.ι

Definition 2.9 (the level of the image)**.** In Setting 1.1 let ϑ be a tame character of D.

(a) $\mathsf{P}_{\mathrm{last}}(D,\vartheta)$ is the group of the families $\kappa=(\kappa_w)$, indexed by the chosen places and the places of $Q(\vartheta)$, of matrices $\kappa_w \in \mathrm{GL}_{\underline{Y}_m(D)}(\mathbb{F}_w)$ that are block upper triangular for the blocks of $\underline{Y}_m(D)$ and equal to 1 at the chosen places.

(b) For $\kappa \in \mathsf{P}_{\mathrm{last}}(D,\vartheta)$, $\mathrm{lch}_{D,\vartheta}(\kappa)$ is the product, over these places w and over $\nu \in \{1,\dots,m\}$, of the values of $\psi^{\uparrow}_{\nu-1}(D,\vartheta)$ at w on the determinant of the ν-th diagonal block of κ_w.

(c) For a form F of principal level on $Y_0(D)$, $\iota^{\mathrm{lev}}_{D,\vartheta}(F)$ is $\iota_{D,\vartheta}(F)$, regarded as an element of the space of the algebraic modular forms on $Y_m(D)$ on which every element of $K_0(Y_m(D))$ with reductions $\kappa \in \mathsf{P}_{\mathrm{last}}(D,\vartheta)$ acts by $\mathrm{lch}_{D,\vartheta}(\kappa)$ (Proposition 3.4 shows that it lies there).

(d) For $\gamma \in \mathsf{G}(D)$, $\mathrm{lift}_{D,\vartheta}(\gamma)$ is a chosen element of $K_0(Y_m(D))$ whose reduction is the block diagonal matrix with blocks γ_w and 1 at every chosen place w, and 1 at the places of $Q(\vartheta)$.

LEAN Data.lastResLevel · Data.lastLevelChar · Data.iotaAtLevel · Data.groupLift

Setting 2.10 (filling data that fit a space; recalled from the unit *Filling*)**.** Let S be filling data over E of a shape with a number of hyperbolic planes (Chapter VI): among its components are a prime N, two further primes with product g_{S}, their chosen places, a generator ϖ_{S} of the different, a level K_{S} on the definite part X_0, and Bessel systems at the infinite places with their vectors $W(g_\infty)$ of Bessel functions. Let V be a hermitian space with frame, $\mathcal{Y}$ a grading of V as the set of the shape plus a string, and $\eta \in G_f(X_0)$; assume that S *fits* V with a parameter, weights, the grading $\mathcal{Y}$ and η: the Bessel systems have the types of the parameter and the weights, the bijection of $\mathcal{Y}$ is the standard one of the shape, the type of the parameter is an idempotent kernel, η is central, and $x_{V,f} = u\cdot\eta\cdot\Lambda\cdot k$ for a finite idele u, the lattice basis Λ of the filling data, and an integral matrix k with integral inverse that is congruent to 1 at the chosen places. For a vector $\phi=(\phi_a)$ of coefficients, indexed by the pairs a of a class of X_0 for K_{S} and a Bessel coordinate, and a subgroup Δ of $\Gamma(V)$, the *Poincaré series* is

$$\mathrm{P}_{\mathsf{S}}(\phi,\Delta)(g) = \sum_a \phi_a \sum_{\gamma\in\Delta} \mathrm{cb}_a(\gamma g),$$

where the cut-off Bessel function cb_a is a cut-off times a Bessel function of the real component if a translate of the finite component, determined by the class of a and by η, lies in the principal level $K^{\mathrm{pr}}_{\mathsf{S}}$ at the chosen places, and 0 otherwise. The *column coordinates* cc_{S} send an algebraic modular form on X_0 of level K_{S} to the vector of the Bessel coordinates of its values at representatives of the classes, the Weyl coordinates being changed to Bessel coordinates by a fixed linear isomorphism A.

Definition 2.11 (columns, the Poincaré series and the projection to rows)**.** In Setting 1.1, $\mathrm{Col}(D)$ is the space of the algebraic modular forms on $X_0(D)$ of the weight fixed in the unit *Columns* that are fixed by the level $K^{\mathrm{col}}_0(D)$, and $\mathrm{Col}^{\mathrm{ram}}(D)$ is its subspace of ramified columns (Definition 2.13). The filling data of D fit $Y_0(D)$ with the grading $\mathcal{Y}_0(D)$ (Proposition 4.1).

(a) cc_D is the linear isomorphism from $\mathrm{Col}(D)$ to the space of coefficient vectors that first translates a column by the central element $u_0(D)$ and then takes the column coordinates of Setting 2.10.

(b) P_D is the linear map from $\mathrm{Col}(D)$ to the forms of principal level on $Y_0(D)$ that sends φ to the Poincaré series of $\mathrm{cc}_D(\varphi)$ over all rational points (recalled from the unit *Filling*).

(c) For $\gamma \in \mathsf{G}(D)$, $\mathrm{pr}_D(\gamma)$ is the linear map from the forms of principal level on $Y_0(D)$ to the image of $e_0(D)$ that sends F to $|\mathsf{G}(D)| \cdot e_0(D)(\gamma F)$.

LEAN `Data.columnCoords` · `Data.goodProjTranslate`

The definite side.

Definition 2.12 (admissible combinations; recalled from the note *Two consecutive theta lifts* of this unit)**.** For a natural number n, $O^{(n)}$ is the ring of the complex numbers z with $|\jmath(z)|_\ell \le 1$ for every prime ℓ not dividing n and every ring homomorphism $\jmath\colon \mathbb{C} \to \mathbb{C}_\ell$. Let v be a family of vectors of a complex vector space, $\mathcal{I}$ a set of its indices, n and d natural numbers, p a proposition and B a real number. Then $\mathrm{Adm}(v, \mathcal{I}; n, d; p, B)$ is the set of the vectors $\sum_x r(x)v(x)$, where r is a finitely supported complex function with support in $\mathcal{I}$, with $d \cdot r(x) \in O^{(n)}$ for all x and, if p holds, with $\sum_x |\sigma(r(x))| \le B$ for every field automorphism σ of $\mathbb{C}$. Such a vector is an *admissible combination* of the $v(x)$, $x \in \mathcal{I}$, away from n, with denominator d and, under p, size B.

Definition 2.13 (columns, stages and definite chains; recalled from the units *Columns* and *Exchange* and from the note *Chains of definite theta lifts and the Gauss-sum operator* of this unit)**.** In Setting 1.1, for a natural number j:

(a) $K_j^{\mathrm{col}}(D)$ is the level of $X_j(D)$ of the elements that are congruent to 1 modulo the chosen places and whose last row, the row of the point, is congruent to $(0, \dots, 0, 1)$ modulo $\pi_N(D)$; $\mathrm{St}_j(D)$ is the space of the smooth algebraic modular forms on $X_j(D)$ of the weight of stage j; the ramified columns are the image on $\mathrm{Col}(D)$ of $\prod_{w \in \Pi(D)} (1 - z_w(D))$, where $z_w(D)$ is the translation by the scalar matrix of an integral adele of norm one, fixed in the unit *Columns*, that generates the units modulo w and is 1 at the places other than w and $\overline{w}$;

(b) for a tame character ϑ of D, $k_{D,\vartheta,j}$ is the theta kernel of the definite pair $(X_j(D), X_{j+1}(D))$ with the character $\mu_{D,j+1}(\vartheta^{j+1})$; its data are the elements of the finite part of $\mathcal{S}(\mathrm{Hom}(X_j(D), X_{j+1}(D)))$, and the lift with a datum Φ is a linear map $\mathrm{St}_j(D) \to \mathrm{St}_{j+1}(D)$;

(c) $\mathrm{Tr}(D)$ is the set of the tuples $t = (t_j)_{j \in \mathbb{N}}$ of finite adelic matrices t_j with rows $\underline{X}_{j+1}(D)$ and columns $\underline{X}_j(D)$; for a natural number q, $\mathrm{Tr}_q(D)$ is the set of the t for which $\pi_g \cdot t_j$ is integral at every place not dividing q, for all j (the weight is π_g, the conjugate of $\bar{\pi}_g(D)$); $\mathrm{v}_D(t)_j$ is the normalised vacuum of $\mathrm{Hom}(X_j(D), X_{j+1}(D))$ translated by $\varrho_f(t_j)$;

(d) for data $\Phi = (\Phi_j)$, $\mathrm{C}^{(j)}_{D,\vartheta}(\Phi)\colon \mathrm{St}_0(D) \to \mathrm{St}_j(D)$ is the composite of the first j lifts with the data $\Phi_0, \dots, \Phi_{j-1}$; for paired data $\Phi = (\Phi_i)$ with Φ_i in the tensor product of the data spaces of the lifts $2i+1$ and $2i+2$, $\mathrm{C}^{[p]}_{D,\vartheta}(\Phi)$ is the composite of the first p pairs of lifts, where a pair with datum $s \otimes s'$ is the lift with s'

after the lift with s, extended linearly; for a finitely supported $\Psi\colon \mathrm{Tr}(D)\to\mathbb{C}$, $\mathrm{C}^{(j)}_{D,\vartheta}[\Psi]=\sum_t \Psi(t)\,\mathrm{C}^{(j)}_{D,\vartheta}(\mathrm{v}_D(t).)$;

(e) $\mathrm{res}_D\colon \mathrm{St}_m(D)\to\{\text{algebraic modular forms on } Y_m(D)\}$ is the restriction of the unit *Columns*: restriction to the block diagonal elements $\mathrm{diag}(h,1)$, followed by a branching matrix and multiplication by a power of the conjugates of $\pi_N(D)$.

Definition 2.14 (translate sums, pair translates and reduced vacua)**.** In Setting 1.1 let i be a natural number. The *translate sum* of the note on the Gauss-sum operator, for the index sets $\underline{X}^{\circ}_{2i}(D)$, $\underline{X}_{2i+1}(D)$, $\underline{X}^{\circ}_{2i+2}(D)$, the set of places $\Pi(D)$ and the prime $N(D)$, is the endomorphism

$$\mathsf{T}_{N(D),\Pi(D)}(\underline{X}^{\circ}_{2i}(D),\underline{X}_{2i+1}(D),\underline{X}^{\circ}_{2i+2}(D)) \;=\; \sum_{y}\varrho_f(\mathrm{c}(y))\otimes\varrho_f(\mathrm{r}(y))$$

of $\mathcal{W}_f(\mathrm{Hom}(X_{2i}(D),X_{2i+1}(D)))\otimes\mathcal{W}_f(\mathrm{Hom}(X_{2i+1}(D),X_{2i+2}(D)))$: the sum over the vectors y with entries in $\prod_{w\in\Pi(D)}\mathbb{Z}/N(D)$, indexed by $\underline{X}_{2i+1}(D)$, where $\mathrm{c}(y)$ is the matrix whose last column, that of the point of $\underline{X}_{2i}(D)$, is $-y/N(D)$ at the places of $\Pi(D)$ and which vanishes elsewhere, and $\mathrm{r}(y)$ the matrix whose last row, that of the point of $\underline{X}_{2i+2}(D)$, is the conjugate of that column. For a family $v=(v_j)_{j\in\mathbb{N}}$ of finite data $v_j\in\mathcal{W}_f(\mathrm{Hom}(X_j(D),X_{j+1}(D)))$ the *pair translates* are

$$\tau_D(v)_i \;=\; \mathsf{T}_{N(D),\Pi(D)}(\underline{X}^{\circ}_{2i}(D),\underline{X}_{2i+1}(D),\underline{X}^{\circ}_{2i+2}(D))(v_{2i}\otimes v_{2i+1}),$$

and for $t\in\mathrm{Tr}(D)$ (Definition 2.13(c)) the *reduced vacuum* of t is the pure tensor

$$\mathrm{rv}_D(t)=\tau_D(\mathrm{v}_D(t).)_{\varrho(D)}\otimes\ldots\otimes\tau_D(\mathrm{v}_D(t).)_0,$$

formed with the family $\mathrm{v}_D(t).=(\mathrm{v}_D(t)_j)_j$ of the translated vacua of t.

LEAN `Data.reducedVacuum`

Definition 2.15 (good data and the map $B^{\Psi}_{D,\vartheta}$; recalled from the units *Columns* and *Exchange*)**.** In Setting 1.1 let ϑ be a tame character of D and $\Psi\colon\mathrm{Tr}(D)\to\mathbb{C}$ finitely supported. The map $B^{\Psi}_{D,\vartheta}$ from $\mathrm{Col}(D)$ to the algebraic modular forms on $Y_m(D)$ is $\varphi\mapsto\mathrm{res}_D(\mathrm{C}^{(m)}_{D,\vartheta}[\Psi](\varphi))$. For a twist ϑ of D the function Ψ is a *good datum for* ϑ if

(i) its support lies in $\mathrm{Tr}_{\mathrm{n}(\vartheta)N(D)}(D)$, its values lie in $O^{(\mathrm{n}(\vartheta))}$, and if $Q(\vartheta)=\emptyset$, then $\sum_t|\sigma(\Psi(t))|\le\exp(x^{60})$ for every field automorphism σ of $\mathbb{C}$;

(ii) it is *jointly invariant*: for every tuple (a_j) with $a_j\in K^{\mathrm{col}}_j(D)$ and $a_j=1$ for $j\ge m$, and every linear map β on the tensor product of the data spaces of the first m lifts, $\sum_t\Psi(t)\,\beta(\bigotimes_{j<m}\omega(a_j,a_{j+1})\mathrm{v}_D(t)_j)=\sum_t\Psi(t)\,\beta(\bigotimes_{j<m}\mathrm{v}_D(t)_j)$;

(iii) for every $\varphi\in\mathrm{St}_0(D)$:

$$\mathrm{C}^{(m)}_{D,\vartheta}[\Psi](\varphi)=\sum_t\Psi(t)\,\mathrm{C}^{[\varrho(D)+1]}_{D,\vartheta}(\tau_D(\mathsf{P}_{\Pi}\mathrm{v}_D(t).).)(\varphi),$$

where P_{Π} is the projection of the finite part to the vectors that are vacua at the places of $\Pi(D)$ and their conjugates, applied to every member of the family $\mathrm{v}_D(t).$, and the paired data are the pair translates of Definition 2.14.

Stage functions.

Definition 2.16 (stage functions)**.** In Setting 1.1 let ϑ be a tame character of D, φ a column in $\mathrm{Col}(D)$, $\xi = (\xi_i)_{i\in\mathbb{N}}$ a tuple of real points $\xi_i \in G_\infty(Y_i(D))$ and $y = (y_i)_{i\in\mathbb{N}}$ a tuple of finite points $y_i \in G_f(Y_i(D))$. For a natural number j with $j \le 2\varrho(D)+2$, a grading $\mathcal{Y}$ of $Y_j(D)$ with norm $N(D)$ and a point g of $G(Y_j(D))$, the complex number $\mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}](g)$ is defined by recursion on j:

- $\mathfrak{P}^{(0)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}]$ is the Poincaré series $\mathrm{P}_{\mathsf{S}}(\mathrm{cc}_D(\varphi), \Gamma_B(\mathcal{Y}))$ of Setting 2.10 over the rational points of the Bessel group of $\mathcal{Y}$, for the filling data of D;
- $\mathfrak{P}^{(j+1)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}]$ is the unfolded function $\mathrm{unf}_{y_{j(D)},\mathcal{Y}}(\nu, \mathfrak{d}_j(D,\vartheta); F, (\xi_j, y_j))$ of Definition 2.3, with $\nu = \mu_{D,j+1}(\vartheta^{j+1})$ and $F = \mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}_j(D)]$.

LEAN `Data.unfoldStage`

Definition 2.17 (evaluated data)**.** In Setting 1.1:

(a) for a natural number i, $\mathrm{ev}_{D,i}$ is the *finite evaluation* of the pair of lifts $Y_{2i}(D) \to Y_{2i+1}(D) \to Y_{2i+2}(D)$, a linear map

$$\mathcal{S}(\mathrm{Hom}(Y_{2i+1}(D), Y_{2i}(D)^- \oplus Y_{2i+2}(D))) \longrightarrow \mathcal{W}_f(\mathrm{Hom}(X_{2i}(D), X_{2i+1}(D))) \otimes \mathcal{W}_f(\mathrm{Hom}(X_{2i+1}(D), X_{2i+2}(D))),$$

where the exponent $^-$ denotes the space with the opposite form: it is the finite evaluation, in the sense of the note *Two consecutive theta lifts*, of the middle arrow pair of the gradings $\mathcal{Y}_{2i}(D), \mathcal{Y}_{2i+1}(D), \mathcal{Y}_{2i+2}(D)$ if $i < \varrho(D)$, of the last arrow pair of $\mathcal{Y}_{2\varrho(D)}(D), \mathcal{Y}_{2\varrho(D)+1}(D), \mathcal{Y}_{\mathrm{last}}(D)$ formed with $\pi_N(D)$ if $i = \varrho(D)$, and 0 if $i > \varrho(D)$;

(b) $\mathrm{cut}(D) = g(D)^{\,f(D)\,n_m(D)^2}$;

(c) for a tame character ϑ, a tuple $y = (y_j)$ of finite points $y_j \in G_f(Y_j(D))$ and a natural number j, $\Upsilon_j(D, \vartheta; y) = \omega_\nu^{\mathrm{pr}}(y_j, y_{j+1})\, \Upsilon_j(D, \vartheta)$ with $\nu = \mu_{D,j+1}(\vartheta^{j+1})$;

(d) for a natural number i, $\mathrm{ed}_i(D, \vartheta; y) = \mathrm{ev}_{D,i}(\Upsilon_{2i}(D, \vartheta; y) \boxtimes \Upsilon_{2i+1}(D, \vartheta; y))$, where $\boxtimes$ is the arrow product of two data, a datum on $\mathrm{Hom}(Y_{2i+1}(D), Y_{2i}(D)^- \oplus Y_{2i+2}(D))$.

Lattices along a string.

Definition 2.18 (adapted bases)**.** Let $e \colon X \sqcup \{0, \dots, l-1\} \to I$ be a bijection. The *flag order* of an index $i \in I$ is $\mathrm{fl}_e(i) = 2l$ if i comes from X and $\mathrm{fl}_e(i) = 4a+1$ if i is the a-th string index; a square matrix indexed by I is *triangular for the flag* if its entry at (i, i') vanishes whenever $\mathrm{fl}_e(i) > \mathrm{fl}_e(i')$. Let $\mathcal{Y}$ be a grading of a hermitian space with frame V, let $h, b \in \mathrm{GL}_I(\mathbb{A}_f)$ and let $\beta = (\beta_a)_{a<l}$ be a family of finite ideles. Then (b, β) is adapted to h for $\mathcal{Y}$ means: b is triangular for the flag of e_y; $b^{-1}h \in \mathrm{GL}_I(\hat{\mathcal{O}})$, so that the columns of b and of h span the same lattice; and the diagonal entry of b at the a-th string index is β_a, for every a. For a finite point $y \in G_f(V)$, a pair (b, β) is adapted at y for $\mathcal{Y}$ if (b, β) is adapted to $x_{V,f}\, y$ for $\mathcal{Y}$; then b is an *adapted basis* of the lattice of y and β its *string diagonal*.

LEAN `flagOrder` · `Grading.IsAdaptedBasis` · `Grading.IsAdaptedAt`

Definition 2.19 (near lines)**.** Let $\mathcal{Y}$ be a grading of V with a string of length l, $\mathfrak{a}$ a finite idele, Q a finite set of finite places, n and k natural numbers and $h \in G_f(V)$. Then h has near lines for $(\mathcal{Y}; \mathfrak{a}, Q; n, k)$ means that there is a pair (b, β) that is adapted at h for $\mathcal{Y}$ such that for every string index a and every finite place w

$$\left|\operatorname{ord}_w \beta_a - \operatorname{ord}_w\left((\mathfrak{a}/\overline{\mathfrak{a}})^n\, \epsilon_a\right)\right| \;\le\; \begin{cases} k & \text{if } w \in Q \text{ or } \overline{w} \in Q, \\ 0 & \text{otherwise,} \end{cases}$$

where $\epsilon_a = 1$ if l is odd and, if l is even, $\epsilon_a = \mathfrak{a}^{-1}$ for $2a < l$ and $\epsilon_a = \overline{\mathfrak{a}}$ otherwise. In words: the lattice of h has an adapted basis whose string diagonal has the orders of the reference ideles exactly outside Q and its conjugate, and within k on them.

LEAN `Grading.HasNearLines`

Definition 2.20 (multiplicity of a cut)**.** Let H be a group with subgroups S, A and J, let T be a finite set of left cosets of J in H and t a left coset of J. The *multiplicity* $\operatorname{mult}_{S,A}(T; t)$ is the number of the left cosets of $S \cap A$ in S that contain an element ς with $\varsigma^{-1} t \in T$; it is 0 if there are infinitely many. When T is stable under left multiplication by $S \cap A$, as in all uses, every element of such a coset has this property.

LEAN `coverMultiplicity`

Inputs 2 (other units and the other notes of this unit). In Setting 1.1:

(a) (*Trace*, unit 140) for $j < m$ the frame of $Y_j(D)$ has finite part $\Lambda_j\, k_j$ with Λ_j the graded lattice basis of $\mathcal{Y}_j(D)$ for the ideles $\mathfrak{a}(D) = \alpha/\overline{\hat{\pi}_g(D)}$, the principal idele $\hat{\pi}_N(D)$ of $\pi_N(D)$ and the scale $u_j(D) = (\mathfrak{a}(D)/\overline{\mathfrak{a}(D)})^{\lceil (m-j)/2 \rceil}$, and k_j integral with integral inverse and congruent to 1 at the chosen places; here $\hat{\pi}_g(D)$ is a finite idele generating the ideal of $\bar{\pi}_g(D)$, equal to 1 at the places not dividing it, and $\hat{\pi}_N(D)$ is the finite idele with the components of $\pi_N(D)$. If w or $\overline{w}$ lies in $Q(\vartheta)$ for a tame character ϑ, then w divides $\mathrm{n}(\vartheta)$ and divides neither $\bar{\pi}_g(D)$ nor $N(D)$. Moreover $m = 2\varrho(D) + 2$.

(b) (*Columns*, unit 145) $\Pi(D)$ is a split level for $N(D)$: it is disjoint from its conjugate, the places above $N(D)$ are those of $\Pi(D)$ and their conjugates, and $N(D)$ is a uniformiser at each of them. For every $w \in \Pi(D)$, every ramified column has the form $\psi - z_w(D)\psi$ with $\psi \in \mathrm{Col}(D)$. If $t \in \mathrm{Tr}_q(D)$ and S is a set of places prime to q whose conjugates are not chosen, then $\mathrm{v}_D(t)_j$ is fixed by the projection to the vectors that are vacua at the places of S and their conjugates.

(c) (*Exchange*, unit 147) $|\underline{Y}_j(D)| \le n_m(D)$ for $j \le m$. For $j < m$ the parameters, weights and signs of $Y_j(D)$ and $Y_{j+1}(D)$ correspond, in the sense required by Inputs 1(e).

Inputs 2, continued: the unit *Filling*. In Setting 1.1:

(d) (*Filling*, unit 148) $K_0^{\mathrm{col}}(D)$ is the preimage of the principal level at the chosen places under the inclusion of the finite points of $X_0(D)$ into those of $Y_0(D)$, and the principal level $K_{\mathsf{S}}^{\mathrm{pr}}$ of the filling data of D is $K_D^{\mathrm{ch}}(Y_0(D))$ (in the formal text, by definition). *Terms of the series*, for admissible filling data as in Setting 2.10: (1) if a term $\mathrm{cb}_a(\gamma' g)$, with γ' a rational point of the Bessel group, does not vanish at a point g whose finite component, translated by the representative of a class and by η, lies in the principal level, then a belongs to that class and γ' to the group of the rational unipotent elements that the class conjugates into the principal level; (2) over that group the cut-offs sum to 1, so that the terms $\mathrm{cb}_a(\gamma' g)$ sum to the Bessel function of the real component; (3) *strong approximation for the unipotent group*: for a finite point u of the unipotent group of the shape and any finite point h there is a rational unipotent ς with $h^{-1}u^{-1}\varsigma h$ in the principal level. *Unfolding of Poincaré series*: for admissible filling data as in Setting 2.10, a form z on V and a subgroup Δ of $\Gamma(V)$, the product of z and $\mathrm{P}_{\mathsf{S}}(\phi,\Delta)$ is integrable on $\Delta\backslash G(V)$, with integral $\sum_a \phi_a \int_{G(V)} z\cdot \mathrm{cb}_a$. *The last stage*: there is a linear map R from $\mathrm{St}_m(D)$ to $\mathcal{F}_m(D)$ such that (1) for all tame ϑ, finitely supported Ψ, forms F of principal level and columns φ, if $\mathcal{L}^{(m)}(D,\vartheta)(F) = R(\mathrm{C}^{(m)}_{D,\vartheta}[\Psi](\varphi))$ then $\iota_{D,\vartheta}(F) = B^{\Psi}_{D,\vartheta}(\varphi)$; (2) for every linear functional $\mathtt{t}$ on the values of forms of stage m there is a complex number $C_{\mathtt{t}}$ such that for every $\Xi\in\mathcal{F}_m(D)$, every $\psi\in\mathrm{St}_m(D)$ and every function F on $G(Y_m(D))$ with $F(i_{y_{\mathrm{last}}(D)}(h)) = \langle \mathtt{t},\psi\rangle(\mathrm{diag}(h,1))$ for all h: $\int_{[G(Y_m(D))]} F\overline{\Xi} = C_{\mathtt{t}}\cdot\langle \Xi, R\psi\rangle$. Here $\langle \mathtt{t},\psi\rangle(g) = \mathtt{t}(g_\infty^{-1}\psi(g_f))$ is the *coefficient* of ψ at $\mathtt{t}$, and $\langle\,,\rangle$ the Petersson product.

Inputs 2, continued: the unit *Curve* and the other notes of this unit. In Setting 1.1:

(e) (*Curve*, unit 150) *named data are admissible combinations*: let W be a hermitian space with frame, with index set I, let $\mathfrak{m}$ be a modulus, g' an integer of E and q a natural number with $g'q \in \mathfrak{m}$, let $\mathfrak{e}$ be an integral finite adele with $\mathfrak{e}q \equiv 0$ modulo $\mathfrak{m}$ (when none is named, $\mathfrak{e} = g'$), let Ψ_0 be a function of residue vectors modulo $\mathfrak{m}$ indexed by I (residue matrices, for a space of homomorphisms) with values in $O^{(q)}$, p a proposition and B a real number such that, if p holds, $\sum_x |\sigma(\Psi_0(x))| \leq B$ for every field automorphism σ of $\mathbb{C}$, and let u be a vector of $\mathcal{S}(W)$ and u_0 its projection to the vectors that are vacua at the places of $\mathfrak{m}$ and their conjugates. Then the vector named at the places of $\mathfrak{m}$ by Ψ_0 on u is an admissible combination of the translates $\varrho_f(t)u_0$, over the finite vectors t with $\bar{\mathfrak{e}}\,t$ integral at the places not dividing q, away from q, with denominator the absolute norm of the ideal of g' to the power $|I|$ (which is 0 for $g' = 0$) and, under p, size B. The weight $\bar{\mathfrak{e}}$ of the translates is thus set by $\mathfrak{e}$ and not by g'.

(f) (the note *Two consecutive theta lifts* of this unit) the calculus of admissible combinations (substitution multiplies denominators and sizes; linear and bilinear images; pure tensors; multiplication by a root of unity; clearing a constant); the Weil translate of a translated vacuum by a finite point g is an admissible combination of translated vacua, with coefficient governed by the finite multiplier of g; the finite multiplier and the values of the characters $\mu_{D,j}(\vartheta)$ on determinants have ℓ-adic absolute value 1 at points integral above ℓ; *support of the zero term*, *the double unfolding*, *the double lift*, *equivariance of the finite evaluation* and *admissible evaluation*, each quoted where it is used (§5, §9).

(g) (the note *Chains of definite theta lifts and the Gauss-sum operator* of this unit) for finite points a_j of the spaces $X_j(D)$ and paired data Φ_i, $\mathrm{C}^{[p]}_{D,\vartheta}((\omega(a_{2i}, a_{2i+1}) \otimes \omega(a_{2i+1}, a_{2i+2}))\Phi_i)(a_0\varphi) = a_{2p}\,\mathrm{C}^{[p]}_{D,\vartheta}(\Phi)(\varphi)$, the points acting on forms by right translation; the characters $\mu_{D,j}(\vartheta^j)$ are unramified at the places above $N(D)$, and a scalar pair acts on the finite part through its quotient.

3 The chain of lifts and its level

Lemma 3.1. *In Setting 1.1 let ϑ be a tame character of D and j a natural number.*

(i) *For every place $w \in Q(\vartheta)$, the component of $\psi_{D,j}(\vartheta)$ at w is $\psi_{\vartheta,w}$.*

(ii) *$\mathcal{J}_j(D,\vartheta) \subseteq K^{\mathrm{ch}}_D(Y_j(D))$.*

(iii) *If $j < m$, then the datum $\mathfrak{d}_j(D,\vartheta)$ is an arrow, for the kernel $\mathcal{K}_j(D,\vartheta)$, from the type of $\mathcal{F}_j(D)$ to the type of $\mathcal{F}_{j+1}(D)$, and for the pair with the two groups exchanged it is an arrow from the type of $\overline{\mathcal{F}_{j+1}(D)}$ to the type of $\overline{\mathcal{F}_j(D)}$ (Inputs 1(c)).*

Proof. (i) $\psi_{D,j}(\vartheta) = \omega_D^j \psi_\vartheta$, and $\omega_{D,w}$ is trivial at the places that are not chosen; a place of $Q(\vartheta)$ does not divide $\bar{\pi}_g(D)$ (Inputs 2(a)). (ii) The condition that defines

$\mathcal{J}_j(D,\vartheta)$ contains the condition at the chosen places. (iii) The parameters, weights and signs of $Y_j(D)$ and $Y_{j+1}(D)$ correspond (Inputs 2(c)). By the first statement of Inputs 1(e) the vector v of the Fock model given by the joint harmonic is an edge between the two types, and by the second statement the datum $\mathfrak{d}_j(D,\vartheta) = v \otimes \Upsilon_j(D,\vartheta)$, an edge tensored with an element of the finite part, is an arrow in both directions; the character of the kernel has the weights of the two spaces (the note on the characters of the data). The status of this input, on which every lift of the chain rests, is given after Inputs 1. □

LEAN `Data.liftTamePart_eq_of_mem_Q` · `Data.levelY_le_chosenLevel` · `Data.isArrow_datumY`

Lemma 3.2 (the finite datum is an eigenvector of the level)**.** *In Setting 1.1 let ϑ be a tame character of D and j a natural number. Let $k \in K_0(Y_j(D))$ and $k' \in K_0(Y_{j+1}(D))$, and let $g = (g_w)$ and $g' = (g'_w)$ be the families of their reductions at the chosen places and the places of $Q(\vartheta)$. Assume that for every such place w the first columns of g'_w, those indexed by $\underline{Y}_j(D)$ through $\mathrm{in}_{D,j}$, form the matrix $\binom{g_w}{0}$. Then, for the Weil representation ω of the kernel $\mathcal{K}_j(D,\vartheta)$,*

$$\omega\big((1,k),(1,k')\big)\,\Upsilon_j(D,\vartheta) \;=\; \Big(\prod_w \frac{\psi_j^{\uparrow}(D,\vartheta)_w(\det g'_w)}{\psi_j^{\uparrow}(D,\vartheta)_w(\det g_w)}\Big)\cdot \Upsilon_j(D,\vartheta).$$

Proof. $\Upsilon_j(D,\vartheta)$ is named on the vacuum by the indicator of one residue matrix, the block inclusion $\binom{1}{0}$ modulo the product $\mathfrak{m}$ of the places in question. The Weil operator of an integral pair (k,k') carries the vector named by the indicator of a residue matrix y to the vector named by the indicator of $\overline{k'}\,y\,\overline{k}^{-1}$, the bars denoting reduction modulo $\mathfrak{m}$, times the values of the two twisting characters at $\det k$ and $\det k'$ (Inputs 1(f)). The hypothesis says exactly that $\overline{k'}\binom{1}{0}\overline{k}^{-1} = \binom{1}{0}$ at every place. The twisting character is $\mu_{D,j+1}(\vartheta^{j+1})$ times a power of υ; it has tame part $\psi_j^{\uparrow}(D,\vartheta)$, so its value at the determinant of an element of $K_0(\,\cdot\,)$ is the product of the values of the tame part at the reductions of the determinant, and υ is unramified. This gives the quotient. □

LEAN `Data.thetaKernelY_omega_upsilonY`

Lemma 3.3 (blocks and counts)**.** *(i) For sets R_0, T_0, a natural number j and an index i of R_0 followed by j copies of T_0: $\mathrm{bl}_j(i) = 0$ if and only if i lies in the first block R_0.*

(ii) For finite sets R_0 and T_0 and a natural number j there is a natural number ν such that for every commutative ring R the group of the invertible matrices over R, indexed by R_0 followed by j copies of T_0, that are block upper triangular has $|\,\mathrm{GL}_{R_0}(R)| \cdot |\,\mathrm{GL}_{T_0}(R)|^j \cdot |R|^{\nu}$ elements (the cardinality of an infinite set being counted as 0).

(iii) Let $\mathfrak{X}$ be a system of level places of E: two finite families of finite places, the chosen places and the twist places, no two of them equal or conjugate. For a finite set R_0, the kernel of the reduction of $K_0(\,\cdot\,)$ on R_0 modulo the product $\mathfrak{m}_1$ of all these places equals the kernel of the family of the reductions at these places.

(iv) For $\mathfrak{X}$ as in (iii) and a natural number e, the residue ring of E modulo the e-th power of the product of the chosen places times the product of the twist places has $(\prod_w \mathrm{N}\,w)^e \cdot \prod_v \mathrm{N}\,v$ elements, w running over the chosen and v over the twist places.

(v) For a finite set R_0 and $\mathfrak{X}$ as in (iii), the order of GL_{R_0} of the residue ring modulo $\mathfrak{m}_1$ equals the index in $K_0(\,\cdot\,)$ of the level of the elements congruent to 1 at all places of $\mathfrak{X}$.

Proof. (i) By induction on j: a new copy of T_0 gets the new number $j+1 \neq 0$, and old indices keep their number. (ii) By induction on j, with $\nu = 0$ for $j = 0$. A block upper triangular matrix for $j+1$ has the block form $\left(\begin{smallmatrix} A & B \\ 0 & C \end{smallmatrix}\right)$ with A block upper triangular for j, and it is invertible exactly when A and C are; this is a bijection onto triples (A, B, C) with B arbitrary, so ν grows by the number of entries of B. (iii) Two integral matrices are congruent modulo $\mathfrak{m}_1$ if and only if they are congruent modulo each of its prime factors, which are distinct. (iv) The norm is multiplicative. (v) By (iii) the level is the kernel of the reduction modulo $\mathfrak{m}_1$, which is surjective onto GL_{R_0} of the residue ring. □

Proposition 3.4 (the chain is equivariant)**.** *In Setting 1.1 let ϑ be a tame character of D, $\gamma \in \mathsf{G}(D)$, F a form of principal level on $Y_0(D)$ and $k \in K_0(Y_m(D))$, and let $g = (g_w)$ be the family of the reductions of k at the chosen places and the places of $Q(\vartheta)$. Assume that every g_w is block upper triangular for the blocks of $\underline{Y}_m(D)$, and that at every chosen place w the diagonal block of number 0 of g_w is γ_w. Then*

$$k \cdot \iota_{D,\vartheta}(F) \;=\; \Big(\prod_{w}\prod_{\nu=1}^{m} \psi^{\uparrow}_{\nu-1}(D,\vartheta)_w\big(\det g_w^{(\nu)}\big)\Big) \cdot \iota_{D,\vartheta}(\gamma F),$$

where $k\cdot$ is right translation of algebraic modular forms and $g_w^{(\nu)}$ the ν-th diagonal block of g_w.

Proof. The identification of forms on the definite space with algebraic modular forms commutes with right translation, so the claim is an identity for $\mathcal{L}^{(m)}(D,\vartheta)(F)$. We prove it for $\mathcal{L}^{(j)}(D,\vartheta)(F)$ and every j for which the data of the first j lifts are arrows, by induction on j; for $j = m$ this is Lemma 3.1(iii). For $j = 0$ the chain is the identity, the product is empty, and k acts on a form of principal level through its reductions at the chosen places, which are γ. For the step let g'_w be the upper left block of g_w, on the indices of $\underline{Y}_j(D)$. It is block upper triangular, and $\det g_w = \det g'_w \cdot \det g_w^{(j+1)}$, so g'_w is invertible; choose $k' \in K_0(Y_j(D))$ with the reductions g'_w. For an arrow, right translation by k of the lift of a form equals the lift, with the datum moved by $\omega((1,k'),(1,k))$, of the form translated by k'. The Weil operator acts on $\mathfrak{d}_j(D,\vartheta) = v \otimes \Upsilon_j(D,\vartheta)$ through the finite datum, and by Lemma 3.2 (its hypothesis is the block triangularity) it multiplies $\Upsilon_j(D,\vartheta)$ by $\prod_w \psi^{\uparrow}_j(D,\vartheta)_w(\det g_w)/\psi^{\uparrow}_j(D,\vartheta)_w(\det g'_w) = \prod_w \psi^{\uparrow}_j(D,\vartheta)_w(\det g_w^{(j+1)})$. The induction hypothesis for k' supplies the factors of the blocks $1,\dots,j$, the diagonal blocks of g'_w being those of g_w. □

LEAN `Data.algFormRep_iota`

Taking $\gamma = 1$ and k with reductions in $\mathsf{P}_{\mathrm{last}}(D,\vartheta)$ shows that $\iota_{D,\vartheta}(F)$ lies in the space of Definition 2.9(c), so that $\iota^{\mathrm{lev}}_{D,\vartheta}(F)$ is defined.

Corollary 3.5 (the chain commutes with the finite group)**.** *In Setting 1.1, for a tame character ϑ of D, $\gamma \in \mathsf{G}(D)$ and a form F of principal level on $Y_0(D)$: $\iota_{D,\vartheta}(\gamma F) = \mathrm{lift}_{D,\vartheta}(\gamma) \cdot \iota_{D,\vartheta}(F)$.*

Proof. Apply Proposition 3.4 to $k = \mathrm{lift}_{D,\vartheta}(\gamma)$. Its reductions are block diagonal with blocks γ_w and 1; by Lemma 3.3(i) the entries outside the block of number 0 are those of the identity, so every diagonal block of number $\nu \geq 1$ is the identity and the product of character values is 1. □

LEAN `Data.iota_principalRep`

4 The Poincaré series at Bessel points

Proposition 4.1. *In Setting 1.1 the filling data of D fit the space $Y_0(D)$, with the parameter of the rows, the weights of the columns, the grading $\mathcal{Y}_0(D)$ and the central element $\eta = u_0(D)^{-1}$, in the sense of Setting 2.10.*

Proof. Four of the five conditions are properties of the chosen objects: the Bessel systems were chosen of these types, the bijection of $\mathcal{Y}_0(D)$ is by definition the standard one of the shape, the type of the parameter of the rows is an idempotent kernel (unit *Trace*), and a scalar is central. For the frame, Inputs 2(a) gives $\Lambda_0 k_0$ with Λ_0 the graded lattice basis for the scale $u_0(D)$; an entrywise comparison, using that $u_0(D)$ has norm one, identifies Λ_0 with $u_0(D) \cdot \eta \cdot \Lambda$. □

LEAN `Data.filling_fits`

Lemma 4.2. *In Setting 2.10 let ϕ be a vector of coefficients.*

(i) For a subgroup Δ of $\Gamma(V)$, $\gamma \in \Delta$ and $g \in G(V)$: $\mathrm{P}_{\mathsf{S}}(\phi, \Delta)(\gamma g) = \mathrm{P}_{\mathsf{S}}(\phi, \Delta)(g)$.

(ii) If $g \in G(V)$ and $\mathrm{P}_{\mathsf{S}}(\phi, \Gamma_B(\mathcal{Y}))(g) \neq 0$, then there is $\varsigma \in B_f(\mathcal{Y})$ such that ςg_f lies in the principal level $K_{\mathsf{S}}^{\mathrm{pr}}$, g_f being the finite component of g.

Proof. (i) Reindex the sum over Δ by $\gamma' \mapsto \gamma'\gamma$. (ii) A term $\mathrm{cb}_a(\gamma g)$ is non-zero only if a translate of the finite component of γg by an element of the image of $i_{y,f}$ lies in $K_{\mathsf{S}}^{\mathrm{pr}}$; this translate is ςg_f with ς the finite part of an element of the Bessel group, because γ and the image of i_y lie in it. If no such ς existed, all terms would vanish. □

LEAN `Filling.Fits.poincare_rat_mul` · `Filling.Fits.exists_besselFin_mul_mem_of_ne_zero`

Proposition 4.3 (normal form)**.** *In Setting 2.10, with Weil data for E and S admissible in the sense of the unit* Filling*, let ψ be an algebraic modular form on X_0 of level K_{S}, let $u \in U(\mathcal{Y})$, $a \in G(X_0)$ and $h \in G(V)$ with finite component in $K_{\mathsf{S}}^{\mathrm{pr}}$. Then*

$$\mathrm{P}_{\mathsf{S}}(\mathrm{cc}_{\mathsf{S}}(\psi), \Gamma_B(\mathcal{Y}))(u\, i_y(a)\, h) = \psi_E\Big(-\frac{\sigma(u)}{g_{\mathsf{S}}\varpi_{\mathsf{S}}}\Big) \cdot \Big\langle \mathsf{A}(a_\infty^{-1}\psi(a_f\eta)),\, W(h_\infty)\Big\rangle,$$

where $\sigma(u)$ is the sum of the entries of u just above the diagonal along the frame of the shape, in the coordinates of the filling data, a_∞^{-1} acts on the Weyl coordinates of the weight, and $\langle\,,\rangle$ is the bilinear dot product of coordinate vectors.

Proof. Write $a_f\eta = \gamma\, \mathsf{g}\, k$ with γ a rational point of X_0, g the chosen representative of the class of $a_f\eta$ and $k \in K_{\mathsf{S}}$. *First*, if a point g has finite component, translated by g and η, in the principal level, then $\mathrm{P}_{\mathsf{S}}(\mathrm{cc}_{\mathsf{S}}(\psi), \Gamma_B(\mathcal{Y}))(g) = \langle \mathsf{A}(\psi(\mathsf{g})), W(g_\infty)\rangle$: a term $\mathrm{cb}_{a'}(\gamma' g)$ with $\gamma' \in \Gamma_B(\mathcal{Y})$ can be non-zero only if a' belongs to the class of g and γ' comes from the group of the rational unipotent elements that this class conjugates into the principal level; so the sum over the classes reduces to this class, and over

that group the cut-offs sum to 1 (Inputs 2(d), facts (1) and (2)). *Then*, by strong approximation for the unipotent group (Inputs 2(d), fact (3)), there is a rational unipotent ς such that the finite part of ςu, conjugated by $a_f\eta$, lies in the principal level. By Lemma 4.2(i) the series is unchanged if its argument is multiplied on the left by ς and by $i_y(\gamma^{-1})$, and the first step applies to the new point. The Bessel vector transforms under the real points of X_0 by the Weyl representation, which A intertwines, and under the real unipotent part by the character of σ; the level of ψ absorbs k; and for a unipotent element whose finite part lies in the principal level the value of the character at the real part equals $\psi_E(-\sigma/(g_{\mathsf{S}}\varpi_{\mathsf{S}}))$ of the whole element. Since σ is additive on products of unipotent elements and vanishes on rational points under ψ_E, the factor is the one stated. The remaining level condition holds because K_{S} is the preimage of the principal level and h_f lies in it. □

LEAN `Filling.Fits.poincare_bessel_normal_form`

Proposition 4.4 (the Poincaré series is generic)**.** *In Setting 2.10, with Weil data for E and S admissible, let ψ be an algebraic modular form on X_0 of level K_{S}, and assume $\mathbf{j}\cdot\mathfrak{c}(y) = -(g_{\mathsf{S}}\varpi_{\mathsf{S}})^{-1}$. Then $\mathrm{P}_{\mathsf{S}}(\mathrm{cc}_{\mathsf{S}}(\psi), \Gamma_B(y))$ is generic for y.*

Proof. Left invariance under $\Gamma_B(y)$ is Lemma 4.2(i). For every point g there is a continuous function F_g with $\mathrm{P}(u\,h) = \psi_E(-\sigma(u)/(g_{\mathsf{S}}\varpi_{\mathsf{S}}))\,F_g(h)$ for all $u \in U(y)$ and all h whose finite part differs from that of g by an element of the principal level: if the series vanishes at all such points, take $F_g = 0$; otherwise Lemma 4.2(ii) moves one of these points into the principal level by an element of $B_f(y)$, which is a product of a unipotent element and an element of the image of i_y, and Proposition 4.3 gives F_g explicitly, a continuous function of the real component. The sets of such h are open and cover, and $F_g = \mathrm{P}$ there (take $u = 1$); so the series is continuous. For u as in the definition of genericity, $\mathrm{P}(ug) = \psi_E(-\sigma(u)/(g_{\mathsf{S}}\varpi_{\mathsf{S}}))\mathrm{P}(g)$. Finally $\mathrm{sh}_y = \mathfrak{c}(y)\cdot\mathsf{C}$ for the matrix C of the shape with $\mathrm{tr}(\mathsf{C}u) = \sigma(u) + \overline{\sigma(u^{-1})}$ (an entrywise computation, by cases on the shape). Moreover $\sigma(u^{-1}) = -\sigma(u)$, because σ is additive on products of unipotent elements; so $\mathrm{tr}(\mathrm{sh}_y u) = \mathfrak{c}(y)\,(\sigma(u) - \overline{\sigma(u)})$. Put $\varkappa = -(g_{\mathsf{S}}\varpi_{\mathsf{S}})^{-1}$; by the hypothesis $\varkappa = \mathbf{j}\,\mathfrak{c}(y)$, and $\overline{\varkappa} = -\varkappa$ because $\bar{\mathbf{j}} = -\mathbf{j}$ and $\overline{\mathfrak{c}(y)} = \mathfrak{c}(y)$. Hence

$$\tfrac{\mathbf{j}}{2}\,\mathrm{tr}(\mathrm{sh}_y u) = \tfrac{1}{2}(\varkappa\,\sigma(u) - \varkappa\,\overline{\sigma(u)}) = \tfrac{1}{2}(\varkappa\,\sigma(u) + \overline{\varkappa\,\sigma(u)}),$$

and $\psi_E(\frac{1}{2}(x+\overline{x})) = \psi_E(x)$ for every adele x, the standard character being invariant under conjugation. So the character of the normal form, $\psi_E(\varkappa\,\sigma(u))$, is $\psi_E(\frac{\mathbf{j}}{2}\,\mathrm{tr}(\mathrm{sh}_y u))$. □

LEAN `Filling.Fits.isGeneric_poincare`

5 Stage functions

Lemma 5.1. *In Setting 1.1 let ϑ be a tame character of D, $\varphi \in \mathrm{Col}(D)$, and ξ, y tuples of real and of finite points as in Definition 2.16.*

(i) Let i and j be natural numbers with $j \le i$ and $j \le 2\varrho(D) + 2$, and let ξ', y' be obtained from ξ, y by replacing the entries of index i by a real point ξ'_i and a finite point y'_i. Then $\mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi', y'; \mathcal{Y}] = \mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}]$ for every grading $\mathcal{Y}$ of $Y_j(D)$.

(ii) For every natural number j with $j \le 2\varrho(D) + 1$, the function $\mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}_j(D)]$ is generic for $\mathcal{Y}_j(D)$.

(iii) If y° is the tuple of the chosen representatives of the cosets $y_j\,\mathcal{J}_j(D,\vartheta)$, then $\mathrm{ed}_i(D,\vartheta;y^\circ)=\mathrm{ed}_i(D,\vartheta;y)$ for every natural number i.

Proof. (i) By the recursion, the function of stage j uses only the points of index $<j$. (ii) By the recursion: for $j=0$ it is Proposition 4.4 for the filling data of D (Proposition 4.1), whose hypothesis is the definition of the constant of $\mathcal{Y}_0(D)$; the step is Inputs 1(a), all gradings $\mathcal{Y}_j(D)$ having the same constant. (iii) The representative is $y_j\,v_j$ with $v_j\in\mathcal{J}_j(D,\vartheta)$, so $\Upsilon_j(D,\vartheta;y^\circ)=\omega_\nu^{\mathrm{pr}}(y_j,y_{j+1})\,\omega_\nu^{\mathrm{pr}}(v_j,v_{j+1})\Upsilon_j(D,\vartheta)$, and $\omega_\nu^{\mathrm{pr}}(v_j,v_{j+1})\Upsilon_j(D,\vartheta)=\Upsilon_j(D,\vartheta)$ by Lemma 3.2: the reductions of v_j and v_{j+1} are 1, so its hypothesis holds and the character factor is 1. □

LEAN Data.unfoldStage_update · Data.isGeneric_unfoldStage · Data.evaluatedDatum_out

The next statement is the bridge to the definite side. It uses two results of the note *Two consecutive theta lifts*, stated for an *arrow pair* $\mathcal{R}$ of three gradings $\mathcal{Y}\to\mathcal{Y}'\to\mathcal{Y}''$ with sets X, X', X_0'': such a pair has a finite set X'', a homomorphism $\mathrm{emb}_{\mathcal{R}}\colon G(X_0'')\to G(X'')$ and a finite evaluation. *The double unfolding*: for a function F generic for $\mathcal{Y}$, the iterated integral over $[B(\mathcal{Y}')]$ and $[B(\mathcal{Y})]$ of F times the two constant terms at the string maps is a constant times the integral over $[G(X)]\times[G(X')]$ of F on the image of i_y times the theta function of the zero term of the arrow product of the two data. *The double lift*: such an integral of a coefficient of an algebraic modular form φ against the theta kernel of an arrow tensor is a coefficient of the composite of the two definite lifts of φ.

Proposition 5.2 (even stages are coefficients of definite chains)**.** *In Setting 1.1 let $\xi=(\xi_j)$ be a tuple of real points as in Definition 2.16. Let i be a natural number with $2i<2\varrho(D)+1$, let $\mathcal{Y}$ be a grading of $Y_{2i+2}(D)$ with norm $N(D)$, a finite set X and a string of length l, let $\mathcal{R}$ be an arrow pair, with a finite set Q_0 of hyperbolic planes, of the gradings $\mathcal{Y}_{2i}(D)\to\mathcal{Y}_{2i+1}(D)\to\mathcal{Y}$ whose finite evaluation is $\mathrm{ev}_{D,i}$, and let $\xi^\star\in G_\infty(Y_{2i+2}(D))$. Then there is a linear functional t such that for every tame character ϑ of D, every column $\varphi\in\mathrm{Col}(D)$, every tuple y of finite points with $y_0\in K_D^{\mathrm{ch}}(Y_0(D))$ and every $g\in G(X)$:*

$$\mathfrak{P}^{(2i+2)}_{D,\vartheta,\varphi}[\xi,y;\mathcal{Y}](i_y(g)\cdot(\xi^\star,y_{2i+2}))=\langle\mathsf{t},\mathrm{C}^{[i+1]}_{D,\vartheta}(\mathrm{ed}_\cdot(D,\vartheta;y))(\varphi)\rangle(\mathrm{emb}_{\mathcal{R}}(g)).$$

Proof. By strong induction on i, for all $\mathcal{Y}$, $\mathcal{R}$, $\xi^\star$. *Claim*: there is a functional t_0 such that the function of stage $2i$, on the image of $i_{y_{2i}(D)}$ translated by (ξ_{2i},y_{2i}), is the coefficient at t_0 of the chain of i pairs. For $i=0$ the stage function is the Poincaré series, and Proposition 4.3 with $u=1$ (so that the character is 1) and the hypothesis on y_0 presents it as $\langle\mathsf{A}(a_\infty^{-1}\varphi(a_f)),W(\xi_0)\rangle$, a linear functional of the value of φ; the central translation in cc_D cancels η. For $i>0$ the claim is the induction hypothesis for $i-1$, with the grading $\mathcal{Y}_{2i}(D)$ and the middle arrow pair. Now unfold twice: by Definition 2.16 the function of stage $2i+2$ at the given point is an iterated integral over $[B(\mathcal{Y}_{2i+1}(D))]$ and $[B(\mathcal{Y}_{2i}(D))]$ of the function of stage $2i$, generic by Lemma 5.1(ii), times two constant terms; the real parts of the Weil operators are evaluated at the fixed real points and absorbed in the Fock vectors. By the double unfolding this is a constant times an integral over $[G(X_{2i}(D))]\times[G(X_{2i+1}(D))]$ of the stage function, replaced by its coefficient from the claim, times the theta function of the zero term of the arrow product $\Upsilon_{2i}(D,\vartheta;y)\boxtimes\Upsilon_{2i+1}(D,\vartheta;y)$ translated by the stacked string map. The zero term of an integrated datum is an integrated datum whose finite part is the finite zero term, and by the defining property of the finite

evaluation and the hypothesis on $\mathcal{R}$ this finite part is the arrow tensor of $\mathrm{ed}_i(D,\vartheta;y)$. The double lift, applied to the lifts $2i+1$ and $2i+2$ (theta lifts in the sense required, by Inputs 1(h)), turns the integral into a coefficient of the composite of the two lifts with datum $\mathrm{ed}_i(D,\vartheta;y)$ applied to the chain of i pairs. The functional t so obtained depends on ξ, $\xi^\star$, $\mathcal{R}$ only. $\square$

LEAN `Data.unfoldStage_even`

6 Lattices along a string

Throughout this section, ord_w of an idele is as in Definition 2.1; the formal text works with $-\mathrm{ord}_w$, the logarithm of the valuation.

Lemma 6.1 (adapted bases)**.** *Let $\mathcal{Y}$ be a grading of a hermitian space with frame V, with index set I, a finite set X and a string of length l.*

(i) Let $e\colon X \sqcup \{0,\dots,l-1\} \to I$ be a bijection and A_1, A_2 square matrices over a commutative ring R, indexed by I and triangular for the flag of e. Then for every string index a, with $i = e(a)$: $(A_1A_2)_{ii} = (A_1)_{ii}(A_2)_{ii}$.

(ii) For every $y \in G_f(V)$ there is a pair (b,β) that is adapted at y for $\mathcal{Y}$.

(iii) Let $y \in G_f(V)$ and let (b,β) be adapted at y for $\mathcal{Y}$. Put $\mathsf{k} = (b^{-1}\, x_{V,f}\, y)^{-1}$. For string indices a, a' with $a' \le l-1-a$, the entry of $\mathsf{k}^*\mathsf{k}$ at the string indices (a,a') is $J_V(z_a, z_{a'}) \cdot \overline{\beta_a}\beta_{a'}$.

(iv) If (b,β) is adapted to h for $\mathcal{Y}$ for some matrix $h \in \mathrm{GL}_I(\mathbb{A}_f)$, then the inverses satisfy the same relation with themselves: (b^{-1},β^{-1}) is adapted to b^{-1} for $\mathcal{Y}$.

(v) Let $h, h' \in \mathrm{GL}_I(\mathbb{A}_f)$ with (b,β) is adapted to h for $\mathcal{Y}$ and (b',β') is adapted to h' for $\mathcal{Y}$, and let w be a finite place at which the matrix $h^{-1}h'$ is integral. Then $\mathrm{ord}_w \beta'_a \ge \mathrm{ord}_w \beta_a$ for every string index a.

(vi) In the situation of (v), if instead h and h' have the same component at w, then $\mathrm{ord}_w \beta'_a = \mathrm{ord}_w \beta_a$ for every string index a.

Proof. (i) A string index is alone in its class of the flag order, since the numbers $4a+1$ are distinct and different from $2l$; in the sum $\sum_{i'} (A_1)_{ii'}(A_2)_{i'i}$ triangularity leaves only $i' = i$. (ii) Hermite reduction over $\hat{\mathcal{O}}$ (Inputs 1(d)), applied to the inverse of $x_{V,f}\, y$, gives an invertible b, triangular for the flag, such that $(x_{V,f}\, y)^{-1} b$ is integral with integral inverse. The inverse of a matrix that is triangular for the flag is triangular for the flag, so by (i), applied to $b\, b^{-1} = 1$, the diagonal entries of b at the string indices are units of $\mathbb{A}_f$; let β be this diagonal. (iii) Since $x_{V,f}^* J_V x_{V,f} = 1$ and y is unitary, $\mathsf{k}^*\mathsf{k} = b^* J_V b$. In the flag order the string vectors of grade ≥ 0 come first, by decreasing grade, then X, then the other string vectors. By triangularity the column of b at a string index a' is $\beta_{a'} z_{a'}$ plus a combination of basis vectors that precede $z_{a'}$ in the flag order, and J_V pairs a string vector $z_{a''}$ only with its reverse. For $a' \le l-1-a$ a comparison of flag orders shows that the only term of $b^* J_V b$ at (a,a') is the product of the two diagonal entries with $J_V(z_a, z_{a'})$. (iv) The inverse of a triangular matrix is triangular; $(b^{-1})^{-1} b^{-1} = 1$; and by (i) the string diagonal of b^{-1} is β^{-1}. (v) $b^{-1}b' = (b^{-1}h)(h^{-1}h')(h'^{-1}b')$ is integral at w and triangular, and by (i) and (iv) its entry at the a-th string index is $\beta_a^{-1}\beta'_a$. (vi) Apply (v) twice. $\square$

LEAN mul_apply_string_of_blockTriangular · Grading.exists_isAdaptedAt · Grading.IsAdaptedAt.gram_string_entry · Grading.IsAdaptedBasis.inv · Grading.IsAdaptedBasis.ideleLogVal_le · Grading.IsAdaptedBasis.ideleLogVal_eq

Proposition 6.2 (lattices with the same lines lie in one Bessel orbit)**.** *Let E be stably unramified, $\mathcal{Y}$ a grading of a hermitian space with frame V with a finite set X and a string of length l, and let $h, h' \in G_f(V)$. Let (b, β) be adapted at h for $\mathcal{Y}$ and (b', β') be adapted at h' for $\mathcal{Y}$, and assume $\mathrm{ord}_w \beta'_a = \mathrm{ord}_w \beta_a$ for every finite place w and every string index a with $a \le l - 1 - a$. Then there is $k \in K_0(V)$ with $h'\, k\, h^{-1} \in B_f(\mathcal{Y})$.*

Proof. Multiplying b' on the right by the diagonal matrix that is 1 on X and $\beta'^{-1}_a \gamma_a$ on the string, with $\gamma_a = \beta_a$ for $a \le l - 1 - a$ and $\gamma_a = \beta'_a$ otherwise, gives an adapted basis at h' with string diagonal γ: the factor is integral with integral inverse by the hypothesis. So we may assume $\beta'_a = \beta_a$ on the first half $a \le l - 1 - a$. Let $\mathsf{k} = (b^{-1} x_{V,f} h)^{-1}$ and k' likewise; both lie in $\mathrm{GL}_I(\hat{\mathcal{O}})$. The columns of k at the string indices of the first half form a matrix with an integral left inverse, and so do those of k'. By Lemma 6.1(iii) the two matrices have the same Gram matrix. Witt's theorem over $\hat{\mathcal{O}}$ (Inputs 1(d)) gives $k \in K_0(V)$ carrying the first to the second. In rational coordinates this says that $h'kh^{-1}$, applied to the column of b at a first-half string index, gives the column of b' there. By the description of the Bessel group it remains to see that $h'kh^{-1} - 1$, in rational coordinates, has zero entry (i, i') whenever i' is a string index of grade ≥ 0 and $\mathrm{gr}(i) \le \mathrm{gr}(i')$; the string indices of grade ≥ 0 are those of the first half. Writing the matrix as its product with $b\, b^{-1}$, the entry is a sum over the columns of b at first-half string indices of smaller or equal number (by triangularity of b^{-1}), on which the matrix acts as $b \mapsto b'$; the columns of b and b' at such an index a'' are $\beta_{a''} z_{a''}$ plus string vectors of higher grade, with the same diagonal. A check of the cases gives zero. □

LEAN Grading.IsAdaptedAt.exists_mem_besselFin

For the next three statements recall from the note *Two consecutive theta lifts*: for finite ideles $\mathfrak{a}$, π and a finite adele u of norm one, a grading $\mathcal{Y}$ of V as $X \sqcup \{\mathrm{pt}\}$ plus a string of length l *spans the lattice of* $(\mathfrak{a}, \pi, u)$ if $x_{V,f} = \Lambda\, k$ with $k \in \mathrm{GL}_I(\hat{\mathcal{O}})$ and Λ the *graded lattice basis*: for even l the diagonal matrix with 1 on $X \sqcup \{\mathrm{pt}\}$, $u\,\mathfrak{a}^{-1}$ at the string indices a with $2a < l$ and $u\,\overline{\mathfrak{a}}$ at the others; for odd l the matrix with 1 on X, u on the string, and the column of the point equal to $\overline{\pi}^{-1}$ at the point plus $u(\pi\overline{\pi})^{-1}$ at the middle string vector. And N is *split and squarefree along* a finite set Σ of finite places with the idele π if $N = \pi\overline{\pi}$, π is a uniformiser at the places of Σ and a unit elsewhere, and Σ is disjoint from its conjugate.

Lemma 6.3 (the standard lattice has near lines)**.** *Let $\mathcal{Y}$ be a grading of V as $X \sqcup \{\mathrm{pt}\}$ plus a string of length l, let $\mathfrak{a}$, π be finite ideles and n a natural number such that $\mathcal{Y}$ spans the lattice of $(\mathfrak{a}, \pi, (\mathfrak{a}/\overline{\mathfrak{a}})^n)$, let K be a subgroup of $K_0(V)$, Q a finite set of finite places and $h \in G_f(V)$ such that $\varsigma h \in K$ for some $\varsigma \in B_f(\mathcal{Y})$. Then h has near lines for $(\mathcal{Y}; \mathfrak{a}, Q; n, 0)$.*

Proof. Let $x_{V,f} = \Lambda k$. In rational coordinates ς^{-1} is triangular for the flag with string diagonal 1, by the description of the Bessel group, and so is Λ, with string diagonal $(\mathfrak{a}/\overline{\mathfrak{a}})^n \epsilon_a$. Their product b satisfies $b^{-1} x_{V,f} h = k \cdot (\varsigma h) \in \mathrm{GL}_I(\hat{\mathcal{O}})$ in the coordinates of the frame, and by Lemma 6.1(i) its string diagonal is that of Λ. So all the differences of orders are 0. □

LEAN `Grading.hasNearLines_zero`

Lemma 6.4. *Let $\mathcal{Y}$ be a grading of V as $X \sqcup \{\mathrm{pt}\}$ plus a string of length l with norm N that spans the lattice of $(\mathfrak{a}, \pi, u)$, let N be split and squarefree along Σ with the idele π, and let $h \in G_f(X \sqcup \{\mathrm{pt}\})$ be integral with integral inverse and with the row of the point congruent to $(0, \dots, 0, 1)$ modulo π. Then $i_{\mathcal{Y},f}(h) \in K_0(V)$.*

Proof. In the coordinates of the frame $x_{V,f} = \Lambda k$, $i_{\mathcal{Y},f}(h) - 1 = k^{-1}\Lambda^{-1}(\tilde{h} - 1)\Lambda k$ with $\tilde{h}$ the block matrix of h and 1. For even l the rows and columns $X \sqcup \{\mathrm{pt}\}$ of Λ are those of the identity, and $h - 1$ is integral. For odd l, $\Lambda^{-1}(\tilde{h} - 1)\Lambda$ has the entries of $h - 1$, except that the column of the point is divided by $\overline{\pi}$ and the row of the point is multiplied by $\overline{\pi}$ (so that the entry at the point itself is unchanged); moreover the row of the point of $h - 1$, divided by $-\pi$, stands in the row of the middle string vector, whose entry in the column of the point is the entry of $h - 1$ at the point divided by $-N$. So three congruences are needed. The row of the point of $h - 1$ is $\equiv 0$ modulo π by hypothesis. The integral matrices with integral inverse and with this property form a group, and h is unitary; so $h^{-1} = h^*$ has the property too, which says that the column of the point of $h - 1$ is $\equiv 0$ modulo $\overline{\pi}$. In particular the entry of $h - 1$ at the point is $\equiv 0$ modulo π and modulo $\overline{\pi}$, hence modulo $N = \pi\overline{\pi}$, as π is a uniformiser on Σ, $\overline{\pi}$ on $\overline{\Sigma}$, both are units elsewhere and Σ is disjoint from $\overline{\Sigma}$. So the matrix is integral, and conjugating by $k \in \mathrm{GL}_I(\hat{\mathcal{O}})$ keeps integrality. □

LEAN `Grading.inclXFin_mem_Kf`

Proposition 6.5 (the two halves of a string diagonal)**.** *Let E be stably unramified, $\mathcal{Y}$ a grading of V with a finite set X, a string of length l and norm N, let $h \in G_f(V)$ and let (b, β) be adapted at h for $\mathcal{Y}$. Let N be split and squarefree along Σ with the idele π. Assume: if l is odd, then for no $\varsigma \in B_f(\mathcal{Y})$ and no $w \in \Sigma$ does $(\varsigma h)^{-1}\, i_{\mathcal{Y},f}(K_w(X))\,(\varsigma h) \subseteq K_w(V)$ hold. Then for every string index a and every finite place w: $\mathrm{ord}_w \beta_a + \mathrm{ord}_{\overline{w}} \beta_{l-1-a} \geq 0$.*

Proof. For any adapted pair, Lemma 6.1(iii) with $a' = l - 1 - a$ shows that the number $\overline{\beta_a}\beta_{l-1-a} J_V(z_a, z_{l-1-a})$ is an entry of the Gram matrix of an element of $\mathrm{GL}_I(\hat{\mathcal{O}})$, hence integral; and $J_V(z_a, z_{l-1-a})$ is 1, or $-N$ at the middle index. This is the claim, except when l is odd, a is the middle index and w or $\overline{w}$ lies in Σ, where it gives only $\mathrm{ord}_w \beta_a + \mathrm{ord}_{\overline{w}} \beta_a \geq -1$. For the middle index the claim is symmetric in w and $\overline{w}$, so let $w \in \Sigma$; then $\overline{w} \neq w$. Suppose the claim fails, so that the sum is -1. Let γ be the family with $\gamma_{a'} = \beta_{a'}$ up to the middle index and $\gamma_{a'} = \overline{\beta_{l-1-a'}}^{-1}$ beyond, and d the diagonal matrix with 1 on X and γ on the string; it is an adapted basis of itself. Since $\overline{w} \neq w$, there is a finite point y, equal to 1 outside w and $\overline{w}$, such that $x_{V,f}\, y\, h$ and d have the same component at w. Choose a pair (b', β') adapted at yh (Lemma 6.1(ii)). By Lemma 6.1(vi) its diagonal has the orders of γ at w and those of β away from w and $\overline{w}$. At $\overline{w}$ its orders are at most those of γ, by Lemma 6.1(v) for the matrices $x_{V,f}\, yh$ and d. Indeed, the matrix that compares the two lattices is $(x_{V,f}\, yh)^{-1}\mathsf{d} = (x_{V,f}\, yh)^* J_V \mathsf{d}$, and since $x_{V,f}\, yh$ agrees with d at w, its component at $\overline{w}$ is that of $\mathsf{d}^* J_V \mathsf{d}$. This matrix is the identity on X, and its only non-zero entries on the string are $\overline{\gamma_{a'}}\gamma_{l-1-a'} = 1$ off the middle index and $-N\overline{\gamma_a}\gamma_a$ at the middle index a, whose order at $\overline{w}$ is $1 + \mathrm{ord}_w \beta_a + \mathrm{ord}_{\overline{w}} \beta_a = 0$ by the assumed failure. So the comparison matrix is integral at $\overline{w}$. And the orders at $\overline{w}$ are at least those of β on the first half, by the Gram condition of the first step for (b', β') and, at the middle index, by the failure of the inequality. As $\gamma = \beta$ on the first half, the two

diagonals have the same orders there at every place. So Proposition 6.2 applies to h and yh: there is $k \in K_0(V)$ with $\varsigma = yhkh^{-1} \in B_f(\mathcal{Y})$. For this ς and w the forbidden inclusion holds: for $a_0 \in K_w(X)$, the conjugate $(\varsigma h)^{-1} i_{y,f}(a_0)(\varsigma h)$ is 1 outside w, $\overline{w}$, and at w it is k^{-1} times the conjugate of the block matrix of a_0 and 1 by $\mathfrak{d}^{-1} x_{V,f}$, times k; the lattice of $\mathfrak{d}$ is stable under such block matrices, so this is integral. This contradicts the assumption. □

LEAN `Grading.IsAdaptedAt.ideleLogVal_add_rev_nonpos`

Proposition 6.6 (one lift moves the lines by one step)**.** *Let E have Weil data, with idele α. Let $\mathcal{Y}$ be a grading of V with a string of length l and $\mathcal{Y}'$ a grading of V' with a string of length l', with the same norm N and $l' + 1 = l$. Let $\mathfrak{a}$ be a finite idele, Q a finite set of finite places, n, n', k natural numbers with $n = n'$ if l is odd and $n = n' + 1$ if l is even, let $h \in G(V)$, $h' \in G(V')$, ν a character, v a vector of the Fock model and $\Phi \in \mathcal{S}(\mathrm{Hom}(V, V'))$, and $\mathfrak{b}$ a finite idele. Assume:*

(a) h_f has near lines for $(\mathcal{Y}; \mathfrak{a}, Q; n, k)$;

(b) $\mathfrak{c}(\mathcal{Y})$ and $\mathfrak{a}\overline{\mathfrak{a}}$ have the same order at every finite place;

(c) $\mathrm{ct}_{y,y'}(\nu, v \otimes \Phi)(h, h') \neq 0$;

(d) $\mathrm{ord}_w \mathfrak{b} \leq \mathrm{ord}_w \overline{(\alpha/\mathfrak{a})} + [w \in Q]$ for every finite place w;

(e) $\varrho_f(\mathfrak{b}\, y)\Phi = \Phi$ for every integral finite vector y;

(f) every pair (b', β') that is adapted at h'_f for $\mathcal{Y}'$ has $\mathrm{ord}_w \beta'_a + \mathrm{ord}_{\overline{w}} \beta'_{l'-1-a} \geq 0$ for all string indices a and all finite places w.

Then h'_f has near lines for $(\mathcal{Y}'; \mathfrak{a}, Q; n', k+1)$.

Proof. Let (b, β) be the adapted pair of (a) and (b', β') any adapted pair at h'_f. *Claim*: for every string index a of $\mathcal{Y}'$,

$$\mathfrak{c}(\mathcal{Y})^{\delta_a} \cdot \frac{\overline{\mathfrak{b}}}{\overline{\beta_{l'-a}}\ \alpha\ \beta'_a} \in \hat{\mathcal{O}}, \qquad \delta_a = 1 \text{ if } (l' \text{ odd}) \Leftrightarrow (a \leq l'-1-a), \quad \delta_a = 0 \text{ otherwise.}$$

Granting the claim, take orders at every place: with (b) the claim bounds $\mathrm{ord}_w \beta'_a$ from above by $-\mathrm{ord}_{\overline{w}} \beta_{l'-a}$ plus the order of $\overline{\mathfrak{b}}/\alpha$ and of the power of $\mathfrak{a}\overline{\mathfrak{a}}$; (a) controls $\beta_{l'-a}$ within k on $Q \cup \overline{Q}$ and exactly elsewhere; (d) costs one more unit on Q; and (f) turns the upper bound for one half of β' into the lower bound for the other half. Linear arithmetic gives the near-lines bound for β' with n' and $k+1$.

Proof of the claim. By Inputs 1(g) there is a splitting of $\mathrm{Hom}(V, V')$ along the maps of positive degree for which the constant term at the string map $T_{y,y'}$ is the theta function of the zero term of the Heisenberg translate by this map. By (c) and the support of the zero term (note *Two consecutive theta lifts*: if a datum is fixed by the translations $\varrho_f(\mathsf{M}y)$, y integral, and the finite zero term of its translate by a vector t does not vanish, then t lies in $\mathsf{M}'\hat{\mathcal{O}} + k^{\perp}$, where $\mathsf{M}\mathsf{M}'^{*} = 1$ and k is the isotropic frame of the splitting), applied to the datum moved by the finite parts of (h, h'), which by (e) is fixed by the translations of $\mathfrak{b}$ times the lattice moved by (h, h'): there is an integral vector λ_0 such that $T_{y,y'}$ and $\overline{\mathfrak{b}}^{-1}(h, h')\lambda_0$ have the same pairing with the isotropic frame. Reading this relation in the frames of V and V', for the entries (i', i) with $\mathrm{gr}(i') < \mathrm{gr}(i)$, expresses the entries of $\overline{\mathfrak{b}}\, T_{y,y'}$ there through the matrix $\mathsf{W} = x_{V',f} h'_f \cdot \lambda_0 \cdot (x_{V,f} h_f)^{-1}$. Now $b'^{-1}\, \mathsf{W}\, J_V^{-1} (b^{-1})^{*}$ is integral, because b' and b are adapted and λ_0 is integral. Its entry at the a-th string index of $\mathcal{Y}'$ and the string

index $l'-a$ of $\mathcal{Y}$ is a double sum in which, by the triangularity of b'^{-1} and b^{-1}, only one term survives: the product of the diagonal entries $\beta_a'^{-1}$ and $\overline{\beta_{l'-a}}^{-1}$, of $\overline{\mathfrak{b}}/\alpha$, of the multiple of the string map at z_a (which is 1, $\mathfrak{c}(\mathcal{Y})$ or $-N\mathfrak{c}(\mathcal{Y})$, by Definition 2.3) and of the entry of J_V^{-1} at $(z_a, z_{l'-a})$, which is 1, or $-N^{-1}$ when z_a is the middle vector of $\mathcal{Y}$. The multiple $-N\mathfrak{c}(\mathcal{Y})$ occurs exactly at the middle vector, where the factor $-N^{-1}$ cancels $-N$; so the product of the last two factors is $\mathfrak{c}(\mathcal{Y})$ or 1, and comparing the cases of Definition 2.3 with the definition of δ_a shows that it is $\mathfrak{c}(\mathcal{Y})^{\delta_a}$. This is the claim. □

LEAN `Grading.HasNearLines.step`

Lemma 6.7 (valuations of the data)**.** *In Setting 1.1:*

(i) the ideal of $E(D)$ generated by $\bar{\pi}_g(D)$ has absolute norm $g(D)^{f(D)}$;

(ii) for every finite place w, the idele $\hat{\pi}_g(D)$ of Inputs 2(a) and $\bar{\pi}_g(D)$ have the same order at w;

(iii) for every natural number j with $j \le 2\varrho(D)+1$ and every finite place w, the constant $\mathfrak{c}(\mathcal{Y}_j(D))$ and the idele $\mathfrak{a}(D)\overline{\mathfrak{a}(D)}$ have the same order at w;

(iv) for every natural number j with $j \le 2\varrho(D)+1$, the grading $\mathcal{Y}_j(D)$ spans the lattice of $(\mathfrak{a}(D), \hat{\pi}_N(D), u_j(D))$, $\hat{\pi}_N(D)$ the principal idele of $\pi_N(D)$;

(v) for a tame character ϑ of D and a hermitian space with frame V over $E(D)$, with a finite index set: every element of $K_D^{\mathrm{ch}}(V)$ that is 1 at the places of $Q(\vartheta)$ is congruent to 1 modulo every chosen place and every place of $Q(\vartheta)$.

Proof. (i) The ideal is the product of the chosen places, and those above g_i have norm g_i and are $f(D)$ in number. (ii) Both orders are the multiplicity of w in the ideal of $\bar{\pi}_g(D)$. (iii) By the self-duality of the Weil data, $\mathbf{j}\alpha\overline{\alpha}$ has at w the order of the inverse different, which $\varpi(P,\mu)^{-1}$ generates; so $(\mathbf{j}\, g(D)\, \varpi(P,\mu))^{-1}$ has the order of $\alpha\overline{\alpha}/g(D)$, and $\mathfrak{a}(D)\overline{\mathfrak{a}(D)} = \alpha\overline{\alpha}/(\hat{\pi}_g(D)\overline{\hat{\pi}_g(D)})$, where $\hat{\pi}_g(D)\overline{\hat{\pi}_g(D)}$ has the order of $\bar{\pi}_g(D)\overline{\bar{\pi}_g(D)} = g(D)$ by (ii). (iv) This is Inputs 2(a), by the definition of the spaces and of the gradings. (v) At a chosen place this is the definition of $K_D^{\mathrm{ch}}(V)$; at a place of $Q(\vartheta)$ an element with component 1 reduces to 1. □

Proposition 6.8 (where a stage function lives)**.** *In Setting 1.1 let ϑ be a tame character of D, ξ and y tuples of real and of finite points as in Definition 2.16 with $y_0 \in K_D^{\mathrm{ch}}(Y_0(D))$, let $\varphi \in \mathrm{Col}^{\mathrm{ram}}(D)$ be a ramified column, j a natural number with $j \le 2\varrho(D)+1$, and $g \in G(Y_j(D))$ a point with $\mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi, y; \mathcal{Y}_j(D)](g) \neq 0$. Then*

$$g_f \text{ has near lines for } (\mathcal{Y}_j(D); \mathfrak{a}(D), Q(\vartheta); \lfloor (m-j+1)/2 \rfloor, j).$$

Proof. By induction on j. For $j=0$, Lemma 4.2(ii) moves g_f into the principal level by an element of the finite Bessel group, and Lemma 6.3 applies, by Lemma 6.7(iv) with $u_0(D) = (\mathfrak{a}(D)/\overline{\mathfrak{a}(D)})^{\lfloor (m+1)/2 \rfloor}$. For the step from j to $j+1$: the value at g is an integral over $\varsigma \in [B(\mathcal{Y}_j(D))]$ of the stage function at $\varsigma \cdot (\xi_j, y_j)$ times a constant term, so both factors are non-zero for some ς. The induction hypothesis at that point is hypothesis (a) of Proposition 6.6, which we apply with $\mathfrak{a} = \mathfrak{a}(D)$, $Q = Q(\vartheta)$, the datum $\mathfrak{d}_j(D,\vartheta) = v \otimes \Upsilon_j(D,\vartheta)$ and $\mathfrak{b}$ a generator of the product $\mathfrak{m}$ of the chosen places and the places of $Q(\vartheta)$; the parities of the string lengths match the exponents.

(b) is Lemma 6.7(iii). (d): the order of $\mathfrak{b}$ at w is the multiplicity of w in the ideal of $\bar{\pi}_g(D)$ plus $[w \in Q(\vartheta)]$, and $\alpha/\mathfrak{a}(D) = \overline{\hat{\pi}_g(D)}$. (e): $\Upsilon_j(D,\vartheta)$ is named on the vacuum by an indicator modulo $\mathfrak{m}$; by Inputs 2(e) with $g' = 0$, $q = 1$ and $\mathfrak{e} = \mathfrak{b}$ (so that $\mathfrak{e}\,q \equiv 0$ modulo $\mathfrak{m}$) it is a combination of translates $\varrho_f(t)$ of the vacuum with $\overline{\mathfrak{b}}t$ integral at every place. Only this support is used: the denominator that the Input gives for $g' = 0$ is 0 and says nothing about the coefficients. Now $\varrho_f(\mathfrak{b}y)$ fixes the vacuum for integral y and commutes with $\varrho_f(t)$ up to the value of the additive character at the pairing of $\mathfrak{b}y$ and t, which is 1 because $\overline{\mathfrak{b}}t$ is integral (Input 1(a) and (e) of the note *Two consecutive theta lifts*: the standard lattice is self-dual). (f) follows from Proposition 6.5 for $\mathcal{Y}_{j+1}(D)$, with $\Sigma = \Pi(D)$ and the principal idele $\hat{\pi}_N(D)$ of $\pi_N(D)$ (Inputs 2(b)), once its hypothesis is verified.

So let the string of $\mathcal{Y}_{j+1}(D)$ be odd, that is $j+1 = 2i+2$ for a natural number i, and suppose that for some $\varsigma \in B_f(\mathcal{Y}_{j+1}(D))$ and $w \in \Pi(D)$ the inclusion of Proposition 6.5 holds at the point g_f. Write $\varsigma^{-1} = u\, i_{\mathcal{Y}_{j+1}(D)}(a_0)$ with u unipotent, and $\varphi = \psi - z_w(D)\psi$ with $\psi \in \mathrm{Col}(D)$ (Inputs 2(b)). By Proposition 5.2 for the pair index i, with the real point of g and after replacing the entry of ξ and y of index $2i+2$ (Lemma 5.1(i),(iii)), the function of stage $2i+2$ on the middle grading is a coefficient of the chain of $i+1$ pairs. The central element of $z_w(D)$ is a scalar of norm one supported at w and $\overline{w}$; by Inputs 2(g) the chain of pairs of $z_w(D)\psi$ is the right translate by this scalar of the chain of pairs of ψ, the character factors being trivial because the characters are unramified above $N(D)$. Moving u out by genericity (a string of odd length makes every unipotent element raise grades by 2), the stage function at g becomes the difference of two values of the same coefficient, at a point and at its translate by the scalar; by the assumed inclusion this translate differs from the point by an element of $\mathcal{J}_{j+1}(D,\vartheta)$ — a place of $\Pi(D)$ is neither chosen nor in $Q(\vartheta)$ — and the evaluated data depend only on cosets modulo these levels (Lemma 5.1(iii)). The two values agree and the stage function vanishes at g, against the assumption. □

7 Periods as finite sums

Lemma 7.1. *Let H be a group with subgroups S, A, J.*

(i) For a finite set T of left cosets of J, an element $p \in S$ and a left coset t of J: $\mathrm{mult}_{S,A}(T; p\,t) = \mathrm{mult}_{S,A}(T; t)$.

(ii) Let H be a measurable group with a left invariant measure, written vol*, let J be a measurable subgroup and T_0 a non-empty finite set of left cosets of J. Then the union of the cosets in T_0 has measure $|T_0| \cdot \mathrm{vol}(J)$.*

Proof. (i) Left multiplication by p^{-1} is a bijection of the cosets of $S \cap A$ in S that carries the set counted for $p\,t$ to the set counted for t. (ii) The union is disjoint and every coset is a left translate of J. □

LEAN `coverMultiplicity_smul` · `measure_union_cosets`

Proposition 7.2 (a cut with multiplicities of prime-power type)**.** *Let V be a hermitian space with frame, let S, A, J, H_0 be subgroups of $G_f(V)$ with A and J levels, $J \subseteq A \subseteq H_0$, let K be a compact subset of $G_f(V)$, q a natural number and W a set*

of finite points. Assume: every $h \in \mathsf{K}$ lies in H_0 and has a natural number n with $(huh^{-1})^{q^n} \in A$ for all $u \in J$; and for every $h \in \mathsf{W}$ there is $\varsigma \in S$ with $\varsigma h \in \mathsf{K}$. Then there is a finite set T of left cosets of J such that

(i) for every $p \in S \cap A$ and every coset t: $t \in T$ if and only if $p\,t \in T$;

(ii) every h with $hJ \in T$ lies in H_0;

(iii) for every h with $hJ \in T$ or $h \in \mathsf{W}$, the multiplicity $\mathrm{mult}_{S,A}(T; hJ)$ divides a power of q.

Proof. Let C be a set of cosets hJ, $h \in \mathsf{K}$, that meets every S-orbit of such cosets exactly once, and let T be the set of the cosets $p\,t$ with $p \in S \cap A$, $t \in \mathsf{C}$. It is contained in the image of the compact set $A\mathsf{K}$ in the discrete space of cosets of the open subgroup J, hence finite. (i) holds by construction. (ii): if $hJ = p\,h_0 J$ with $h_0 \in \mathsf{K}$, then $h \in A\,H_0\,J \subseteq H_0$. (iii): a coset hJ in T, and by the second hypothesis also the coset of a point of W, lies in the S-orbit of some $h_0 J \in \mathsf{C}$, $h_0 \in \mathsf{K}$; by Lemma 7.1(i) it has the multiplicity of $h_0 J$. Let S_0 be the stabiliser of $h_0 J$ in S. Since C meets the orbit once, the elements $\varsigma \in S$ with $\varsigma^{-1} h_0 J \in T$ are those of $S_0\,(S \cap A)$, so the multiplicity is the index of $S_0 \cap A$ in S_0, which is finite because $h_0 A h_0^{-1}$ is commensurable with A. This index divides the order of the quotient of S_0 by the normal core of $S_0 \cap A$. Every element of S_0 lies in $h_0 J h_0^{-1}$, so by the first hypothesis a fixed q^n-th power of it lies in A, and the same holds for its conjugates in S_0: every element of the finite quotient has order dividing q^n. A finite group all of whose elements have order a power of q has order dividing a power of q. □

LEAN `exists_cut_coverMultiplicity_dvd`

Proposition 7.3 (a period over the Bessel quotient as a finite sum)**.** *Let E have Weil data, $\mathcal{Y}$ a grading of a hermitian space with frame V, with a finite set X and a string, A a level of V and a a complex function on $G_\infty(V)$. There is a complex number C such that the following holds for every function F_1 on $G(V)$ that is generic for $\mathcal{Y}$, every automorphic function F_2 on $G(V)$, every level J of V, every finite set T of cosets of J in $G_f(V)$ and every complex function b on the cosets of J; write $F = F_1 F_2$. If*

(a) F is integrable on $\Gamma_B(\mathcal{Y})\backslash G(V)$;

(b) for every $p \in B_f(\mathcal{Y}) \cap A$ and every coset t: $t \in T$ if and only if $p\,t \in T$;

(c) $\mathrm{mult}_{B_f(\mathcal{Y}),A}(T; g_f J) \neq 0$ for every $g \in G(V)$ with $F(g) \neq 0$;

(d) $\int_{[B(\mathcal{Y})]} F(\varsigma g)\,d\varsigma = [K_0(V) : J] \cdot \mathsf{a}(g_\infty)\,\mathsf{b}(g_f J)$ for every $g \in G(V)$ with $g_f J \in T$,

then

$$\int_{\Gamma_B(\mathcal{Y})\backslash G(V)} F \;=\; C \cdot \sum_{t \in T} \frac{\mathsf{b}(t)}{\mathrm{mult}_{B_f(\mathcal{Y}),A}(T; t)}.$$

Proof. Normalise the Haar measure of $B_f(\mathcal{Y})$ so that the compact open subgroup $B_f(\mathcal{Y}) \cap A$ has measure 1. The Bessel group acts properly on $G(V)$, so there is a cut-off function for this action: a function β_0 on $G(V)$ whose integral over each orbit of $B(\mathcal{Y})$ is 1. Let $\alpha_0(g_\infty)$ be the integral of β_0 over the finite part of the orbit, and let C be the integral of a against α_0 times the measure of $G_\infty(V)$; it depends on $\mathcal{Y}$, A, a only. Let ψ_T be the function on the cosets of J equal to the inverse of the multiplicity on T and to 0 elsewhere. By (c) the integral of F may be restricted to the set where the multiplicity does not vanish. Integration in stages over $\Gamma_B(\mathcal{Y})\backslash G(V)$ (a result

of the background library on quotient measures, of the type of Weil's integration formula) writes it as the integral, against the density $\alpha_0(g_\infty)\psi_T(g_f J)$, of the inner integrals $\int_{[B(y)]} F(\varsigma g)\, d\varsigma$; this uses the identity

$$\int_{B_f(y)} \psi_T(\varsigma^{-1} t)\, d\varsigma = 1 \qquad \text{for every coset } t \text{ of non-zero multiplicity,}$$

whether t lies in T or not. It holds because the multiplicity is invariant under all of $B_f(y)$ (Lemma 7.1(i)), while the indicator of T is invariant only under $B_f(y) \cap A$, by (b): the integrand is the inverse of the multiplicity of t on the set of the ς with $\varsigma^{-1} t \in T$, which is a union of exactly that many cosets of $B_f(y) \cap A$ (Lemma 7.1(ii)), and it vanishes elsewhere. For a coset of multiplicity zero the integrand vanishes identically; by (c) such cosets carry none of the integral of F. By (d) the inner integrals are $[K_0(V) : J]\, \mathsf{a}(g_\infty)\mathsf{b}(g_f J)$. The density is a product, the real part gives C, and the finite part is a sum over the finite set T of $\psi_T(t)\mathsf{b}(t)$ times the measure of a coset of J, which is $[K_0(V) : J]^{-1}$ (Lemma 7.1(ii)); the two indices cancel. □

LEAN `Grading.exists_integral_eq_sum_over_cut`

Proof of Theorem C. The case $j = 0$. Take $A = K_D^{\mathrm{ch}}(Y_0(D))$; by Inputs 2(d) it contains $i_{y_0(D),f}(K_0^{\mathrm{col}}(D))$. For a tame character ϑ apply Proposition 7.2 with $S = B_f(y_0(D))$, $J = \mathcal{J}_0(D, \vartheta) \subseteq A$ (Lemma 3.1(ii)), $\mathsf{K} = A$, $H_0 = K^{(\mathrm{n}(\vartheta))}(Y_0(D)) \cap A$, $q = \mathrm{n}(\vartheta)$ and W the set of the points where some function of stage 0 does not vanish. For $h \in A$ and $u \in J \subseteq A$ the conjugate huh^{-1} lies in the group A, so the exponent $n = 0$ works; and Lemma 4.2(ii) moves a point of W by an element of S into the principal level of the filling data of D, which is A (Inputs 2(d)).

The case $j \neq 0$. Take $A = K_0(Y_j(D))$; it contains $i_{y_j(D),f}(K_j^{\mathrm{col}}(D))$ by Lemma 6.4, whose hypotheses are Lemma 6.7(iv), Inputs 2(b) and the congruence condition in the definition of $K_j^{\mathrm{col}}(D)$. For every finite point h choose an adapted pair $(b(h), \beta(h))$ (Lemma 6.1(ii)). Fix ϑ, put $Q = Q(\vartheta)$ and call the *profile* of h the family of the integers $\mathrm{ord}_w \beta(h)_a - \mathrm{ord}_w \beta(1)_a$, for the string indices a and the places w in $Q \cup \overline{Q}$. For every profile with values between $-j$ and j choose a point, with this profile if there is one, and keep its components at the places of $Q \cup \overline{Q}$ only, setting the others to 1; let K be the union of the finitely many cosets $h_0\, K_0(Y_j(D))$ of these points h_0. It is compact. Apply Proposition 7.2 with $S = B_f(y_j(D))$, $J = \mathcal{J}_j(D, \vartheta)$, $H_0 = K^{(\mathrm{n}(\vartheta))}(Y_j(D))$, $q = \mathrm{n}(\vartheta)$ and W the set of the finite parts of the points where a function of stage j of a ramified column, with $y_0 \in K_D^{\mathrm{ch}}(Y_0(D))$, does not vanish. The hypotheses: a point of K is integral at the places not dividing $\mathrm{n}(\vartheta)$, because the places of $Q \cup \overline{Q}$ divide it (Inputs 2(a)); for $u \in J$ the conjugate huh^{-1} agrees with an element of $K_0(\,\cdot\,)$ outside $Q \cup \overline{Q}$, and at a place w of Q the component u_w of u is congruent to 1 modulo w, that is, $u_w \in 1 + \mathfrak{p}_w \mathrm{M}_I(\mathcal{O}_w)$, where $\mathfrak{p}_w$ is the maximal ideal of $\mathcal{O}_w$ and $\mathrm{M}_I(\mathcal{O}_w)$ the ring of the matrices over $\mathcal{O}_w$. Let ℓ be the residue characteristic of w. By the binomial expansion, the ℓ-th power maps $1 + \mathfrak{p}_w^\nu \mathrm{M}_I(\mathcal{O}_w)$ into $1 + \mathfrak{p}_w^{\nu+1} \mathrm{M}_I(\mathcal{O}_w)$ for every $\nu \geq 1$; so $u_w^{\ell^\nu} \in 1 + \mathfrak{p}_w^{\nu+1} \mathrm{M}_I(\mathcal{O}_w)$ for all $u \in J$ and all ν. These subgroups are stable under powers, and ℓ divides $\mathrm{n}(\vartheta)$. As they form a basis of neighbourhoods of 1, one exponent n, chosen for the finitely many places of Q, puts $u_w^{\mathrm{n}(\vartheta)^n}$ into the open subgroup $h_w^{-1}\, \mathrm{GL}_I(\mathcal{O}_w) h_w$ for every $u \in J$ at once; at the conjugate place the component of $(huh^{-1})^{\mathrm{n}(\vartheta)^n}$ is then integral with integral inverse as well, the element being unitary. Finally let $h \in \mathsf{W}$. By Proposition 6.8 the lattice of h has near lines; by Lemma 6.3 for $h = 1$ and $Q = \emptyset$ the string diagonal at 1 has exactly

the reference orders; so the profile of h has values in $[-j, j]$ and the diagonal of h has the orders of that of 1 outside $Q \cup \overline{Q}$. Let h_0 be the chosen point with this profile. By Lemma 6.1(vi), adapted bases at h_0 and at h have string diagonals of the same orders at every place, and Proposition 6.2 gives $k \in K_0(\,\cdot\,)$ with $\varsigma = h_0\, k\, h^{-1} \in B_f(\mathcal{Y}_j(D))$; then $\varsigma h = h_0 k \in \mathsf{K}$. The three conclusions of Proposition 7.2 are (i), (ii) and (iii) of the theorem; for $j = 0$, (ii) includes $h \in A$. □

8 The unfolding

Proof of Theorem B. By induction on j, for all $\mathcal{Y}$ and all functions a.

$j = 0$. Take $C = \mathsf{a}(1)$, the value at the tuple of trivial points, and $\mathsf{w} = S(1)$, the value at the tuple of trivial cosets: a combination with one coefficient 1, which is (i). (ii) holds because no index is moved: $q' = q$ for every q, so that $\Omega(S(1)) = S(1)$. For (iii), unfold the Poincaré series twice (Inputs 2(d)): the integral over $[G(Y_0(D))]$ of z times $\mathrm{P}_D\varphi$, the series over all rational points, and the integral over $\Gamma_B(\mathcal{Y})\backslash G(Y_0(D))$ of z times the series over $\Gamma_B(\mathcal{Y})$, which is the function of stage 0, are both equal to $\sum_a \phi_a \int_G z \cdot \mathrm{cb}_a$. The second is integrable, so the hypothesis at the trivial tuples evaluates it as $\mathsf{a}(1)L(S(1))$.

From j to $j+1$. Theorem C at j gives the level A and, for every ϑ, a cut $T = T(\vartheta)$. For every tuple ξ let $C(\xi)$ be the constant of Proposition 7.3 for the grading $\mathcal{Y}_j(D)$, the level A and the function $\xi'_j \mapsto \mathsf{a}(\xi$ with its entry j replaced by $\xi'_j)$. Apply the induction hypothesis at j to the grading $\mathcal{Y}_j(D)$ and the function $\xi \mapsto C(\xi)$; it gives a constant C. Given ϑ, M and S, put

$$S'(q) = \sum_{t \in T} \frac{1}{\mathrm{mult}_{B_f(\mathcal{Y}_j(D)),A}(T;t)}\; S(q \text{ with its entry } j \text{ replaced by } t)$$

and let w be the vector that the induction hypothesis gives for S'.

(i) Each $S'(q)$ is a combination of values of S at tuples whose new entry is integral away from $\mathrm{n}(\vartheta)$ (Theorem C(ii)), with coefficients $1/\mathrm{mult}_{B_f(\mathcal{Y}_j(D)),A}(T;t)$ that lie in $O^{(\mathrm{n}(\vartheta))}$, because the multiplicities divide powers of $\mathrm{n}(\vartheta)$ (Theorem C(iii)). If $Q(\vartheta) = \emptyset$ the sum of the absolute values of their conjugates is at most $|T|$, and T injects into the quotient of $K_0(Y_j(D))$ by the principal congruence subgroup of $\bar{\pi}_g(D)$: its elements are integral everywhere, and two of them that are congruent modulo $\bar{\pi}_g(D)$ differ by an element of $\mathcal{J}_j(D,\vartheta)$ (Lemma 6.7(v)). The order of that quotient is at most the norm of $\bar{\pi}_g(D)$ to the power $|\underline{Y}_j(D)|^2$, which is at most $\mathrm{cut}(D)$ by Lemma 6.7(i) and Inputs 2(c). Substituting these combinations into the admissible combination for S' multiplies the sizes: (i) holds with $\mathrm{cut}(D)^j \cdot \mathrm{cut}(D)$.

(ii) Let b and Ω be as in (ii) for $j+1$. Then $\Omega(S'(q))$ is the sum over $t \in T$ of the same coefficients times S at the moved tuple with entry $i_{\mathcal{Y}_j(D),f}(b_j)\, t$ at j. Since $i_{\mathcal{Y}_j(D),f}(b_j) \in B_f(\mathcal{Y}_j(D)) \cap A$, multiplication by it permutes T (Theorem C(i)) and keeps the multiplicity (Lemma 7.1(i)); so $\Omega(S'(q)) = S'(q')$ with q' the tuple moved at the indices $< j$, and the induction hypothesis gives $\Omega(\mathsf{w}) = \mathsf{w}$.

(iii) Let z, φ, L satisfy the hypothesis for $j+1$ and the grading $\mathcal{Y}$. By Lemma 3.1(iii) and Inputs 1(c), with $z^\flat$ the descent of z times the index $[K_0(Y_j(D)) : \mathcal{J}_j(D,\vartheta)]$,

$$\int_{[G(Y_{j+1}(D))]} z \cdot \mathcal{L}^{(j+1)}(D,\vartheta)(\mathrm{P}_D\varphi) = \int_{[G(Y_j(D))]} z^\flat \cdot \mathcal{L}^{(j)}(D,\vartheta)(\mathrm{P}_D\varphi),$$

and $z^\flat$ is a form of the conjugate type on $Y_j(D)$. It remains to verify the hypothesis of (iii) at j for $z^\flat$, the function $C(\,\cdot\,)$, the map S' and the same L. Fix ξ and y and let F be the function of stage j on $\mathcal{Y}_j(D)$ times $z^\flat$, assumed integrable. Proposition 7.3 applies to it: the stage function is generic (Lemma 5.1(ii)), T is stable (Theorem C(i)), and where F does not vanish the multiplicity divides a power of $\mathrm{n}(\vartheta)$, so it is not zero (Theorem C(iii)). Its hypothesis (d): at a point (ξ'_j, t) with $t \in T$, the value of $z^\flat$ is the index $[K_0(Y_j(D)) : \mathcal{J}_j(D,\vartheta)]$ times the theta integral of z, and by one unfolding step (Inputs 1(b)) the inner integral over $[B(\mathcal{Y}_j(D))]$ of the stage function times that theta integral is the integral over $\Gamma_B(\mathcal{Y})\backslash G(Y_{j+1}(D))$ of the function of stage $j+1$ for the tuples with entry (ξ'_j, t) at j, times z, and this product is integrable by the same Input, which is the premise that the hypothesis for $j+1$ asks for; the stage function at j does not see the new entry (Lemma 5.1(i)). By the hypothesis for $j+1$ this integral is a at the changed tuple times L of S at the changed tuple of cosets; the conditions $y_{2\varrho(D)+2} = 1$ and $y_0 \in K_D^{\mathrm{ch}}(Y_0(D))$ persist, the latter for $j = 0$ by Theorem C(ii). Proposition 7.3 now gives $\int F = C(\xi)\sum_{t\in T} L(S(\dots t \dots))/\operatorname{mult}_{B_f(y_j(D)),A}(T;t) = C(\xi)\,L(S'(\text{cosets of } y))$, which is the hypothesis at j. □

9 From an invariant combination to a good datum

In this section the translate sums and the pair translates are those of Definition 2.14, and *vac* is the vacuum of the space in question.

Proposition 9.1 (the pairs of lifts evaluate admissibly)**.** *In Setting 1.1 let i be a natural number with $i \le \varrho(D)$. Then* $\mathrm{ev}_{D,i}$ *is an admissible evaluation for $N(D)$, $\Pi(D)$ and $\bar\pi_g(D)$ in the sense of the note* Two consecutive theta lifts*: there is a complex number C_i such that for every natural number n prime to $N(D)$, every proposition p and every finite vector t_0 of* $\mathrm{Hom}(Y_{2i+1}(D), Y_{2i}(D)^- \oplus Y_{2i+2}(D))$ *for which $\bar\pi_g(D)\,t_0$ is integral on the rows of the first summand and $\pi_g\,t_0$ on the rows of the second, at all places not dividing n (two conjugate weights),*

$$\mathrm{ev}_{D,i}(\varrho_f(t_0)\mathrm{vac}) \in \mathrm{Adm}(v, \mathcal{J}_n; n, d_i; p, 1),$$
$$v(t_1,t_2) = C_i \cdot \mathsf{T}_{N(D),\Pi(D)}(\underline{X}^\circ_{2i}(D), \underline{X}_{2i+1}(D), \underline{X}^\circ_{2i+2}(D))(\varrho_f(t_1)\mathrm{vac} \otimes \varrho_f(t_2)\mathrm{vac}),$$

where $\mathcal{J}_n$ is the set of the pairs of finite matrices (t_1,t_2) with $\pi_g\,t_1$ and $\pi_g\,t_2$ integral at the places not dividing n, and d_i is the order of $\hat{\mathcal{O}}/\bar\pi_g(D)$ to the power $(n_{2i}(D) + n_{2i+2}(D))\cdot n_{2i+1}(D)$.

Proof. By the definition of $\mathrm{ev}_{D,i}$ this is the theorem *admissible evaluation* of the note *Two consecutive theta lifts* (Theorem D there), applied to the middle pair for $i < \varrho(D)$ and to the last pair for $i = \varrho(D)$. Its hypotheses, in the letters of that theorem: $\Pi(D)$ is a split level for $N(D)$, and $N(D)$ is split and squarefree along it with the principal idele $\hat\pi_N(D)$ of $\pi_N(D)$ (Inputs 2(b)). The middle grading $\mathcal{Y}_{2i+1}(D)$ spans the lattice of $(\mathfrak{a}(D), \hat\pi_N(D), u_{2i+1}(D))$ (Lemma 6.7(iv)). The integral adele β is $\bar\pi_g(D)$, and $\delta = \overline{\hat\pi_g(D)}^{-1}\hat\pi_g(D)$, of norm one, satisfies $\delta = (\overline{\alpha}/\alpha)\cdot(\mathfrak{a}(D)/\overline{\mathfrak{a}(D)})$ because $\mathfrak{a}(D) = \alpha/\overline{\hat\pi_g(D)}$. The family κ is 1 at every index except the point of $\underline{X}_m(D)$ in the last pair, where it is δ. At the places above $N(D)$, $\delta = 1$ and $\bar\pi_g(D)$ is a unit, because chosen places do not divide $N(D)$ (Lemma 6.7(ii)); and $\pi_g\kappa_b$ and $\bar\pi_g(D)\kappa_b$ are integral, δ having at every place the order of $\bar\pi_g(D)/\pi_g$. *The hypothesis on weights*: the zero part of the middle pair joins only indices that carry the same

weight; that of the last pair also joins the point of $\underline{X}_m(D)$ to the only string vector of $\mathcal{Y}_{2\varrho(D)}(D)$, where the two weights are $\bar{\pi}_g(D)$ and $\pi_g\delta$, of the same absolute value at every place: this is the reason for $\kappa = \delta$ there. *The hypothesis on lattices*: scaled neighbour vectors land in the lattices of the outer spaces. In the middle pair this is the lattice lemma of that note (Lemma 4.3 there) for $\mathcal{Y}_{2i}(D)$ and $\mathcal{Y}_{2i+2}(D)$, whose scales $u_{2i}(D)$ and $u_{2i+2}(D)$ are the powers of $\mathfrak{a}(D)/\overline{\mathfrak{a}(D)}$ with exponents $\varrho(D) - i + 1$ and $\varrho(D) - i$ (Lemma 6.7(iv)). In the last pair it is the same lemma for $\mathcal{Y}_{2\varrho(D)}(D)$, with exponent 1, applied to the sum of the two congruences of a neighbour vector, one of them multiplied by the unit ε with $\bar{\varepsilon}\varepsilon = -1$; the frame of the standard space $Y_m(D)$ is 1. □

LEAN `Data.isAdmissibleEval_pairEvalY`

Proposition 9.2 (evaluated data are combinations of reduced vacua)**.** *In Setting 1.1 there is a complex number C such that for every tame character ϑ of D and every tuple $y = (y_j)$ of finite points with $y_j \in K^{(\mathrm{n}(\vartheta))}(Y_j(D))$ for all j:*

$$\mathrm{ed}_{\varrho(D)}(D, \vartheta; y) \otimes \ldots \otimes \mathrm{ed}_0(D, \vartheta; y)$$
$$\in \mathrm{Adm}(C \cdot \mathrm{rv}_D(\cdot), \mathrm{Tr}_{\mathrm{n}(\vartheta)}(D); \mathrm{n}(\vartheta), \mathrm{cut}(D)^{2m}; Q(\vartheta) = \emptyset, 1).$$

Proof. Write $n = \mathrm{n}(\vartheta)$. *Each moved datum.* $\Upsilon_j(D, \vartheta)$ is named by an indicator modulo the product $\mathfrak{m}$ of the chosen places and the places of $Q(\vartheta)$, and $\bar{\pi}_g(D)\, n \in \mathfrak{m}$; by Inputs 2(e) it is an admissible combination, away from n, of translates $\varrho_f(t)\mathrm{vac}$ with $\pi_g t$ integral at the places not dividing n, with denominator a power of the norm of $\bar{\pi}_g(D)$ and size at most 1. The Weil operator of a finite pair (y_j, y_{j+1}) is linear, and by Inputs 2(f) it sends such a translate to an admissible combination of translates of the same kind: the pair is integral at the places not dividing n, so the translations stay in the same group; its finite multiplier has ℓ-adic absolute value 1 for ℓ prime to n, and is 1 when $Q(\vartheta) = \emptyset$, the pair then lying in the stabiliser of the lattice; and the values of the twisting character are ℓ-adic units, of complex absolute value 1. So $\Upsilon_j(D, \vartheta; y)$ is such a combination. *Each pair.* The arrow product is bilinear, and the arrow product of two translated vacua is a root of unity times a translated vacuum of $\mathrm{Hom}(Y_{2i+1}(D), Y_{2i}(D)^- \oplus Y_{2i+2}(D))$, at the vector with rows $-\varepsilon\bar{t}$ on the first summand and t' on the second, which satisfies the integrality of Proposition 9.1: the conjugated block has the weight $\bar{\pi}_g(D)$, the other block the weight π_g. Applying $\mathrm{ev}_{D,i}$ and Proposition 9.1 (with n, prime to $N(D)$), $\mathrm{ed}_i(D, \vartheta; y)$ is an admissible combination of the vectors $v(t_1, t_2)$ of that proposition, each of them C_i times the translate sum of the pair i applied to a tensor of two translated vacua. *The tensor.* A pure tensor of admissible combinations is an admissible combination of the pure tensors, with the product of the denominators and of the sizes; the pure tensor of the vectors $v(t_1, t_2)$ of the pairs is $\prod_i C_i$ times a reduced vacuum, up to the normalisation of the vacuum, which is absorbed in C. The denominators: all are powers of the order of $\hat{\mathcal{O}}/\bar{\pi}_g(D)$, which is $g(D)^{f(D)}$ (Lemma 6.7(i)), with exponents bounded, for each pair, by $4\, n_m(D)^2$; so each pair contributes a divisor of $\mathrm{cut}(D)^4$ and the $\varrho(D) + 1$ pairs a divisor of $\mathrm{cut}(D)^{4(\varrho(D)+1)} = \mathrm{cut}(D)^{2m}$. □

LEAN `Data.exists_isAdmissibleComb_reducedVacuum`

Lemma 9.3. *In Setting 1.1 let ϑ be a tame character of D, $t \in \mathrm{Tr}_{\mathrm{n}(\vartheta)}(D)$ and i a natural number, and let P_Π be the projection of the finite part to the vectors that are vacua at the places of $\Pi(D)$ and their conjugates (Definition 2.15(iii)). Then*

$$(\mathsf{P}_\Pi \otimes \mathsf{P}_\Pi)(\tau_D(\mathrm{v}_D(t).)_i) = \mathrm{v}_D(t)_{2i} \otimes \mathrm{v}_D(t)_{2i+1}.$$

Proof. The places of $\Pi(D)$ and their conjugates do not divide $\mathrm{n}(\vartheta)$ and are not chosen, so $\mathrm{v}_D(t)_j$ is fixed by P_Π (Inputs 2(b)); for such a vector, $\mathsf{P}_\Pi \varrho_f(t')$ is $\varrho_f(t')$ if t' is integral at these places and 0 otherwise (Input 1(f) of the note *Two consecutive theta lifts*). In the sum defining $\tau_D(\mathrm{v}_D(t).)_i$ the vector $-y/N(D)$ is integral at $\Pi(D)$ only for $y = 0$, and that term is the tensor of the two data. □

LEAN `Data.projOnFinPart_pairTranslates`

Lemma 9.4. *In Setting 1.1 let q be a natural number, p a proposition and $t \in \mathrm{Tr}_q(D)$. Then*

$$\mathrm{rv}_D(t) \in \mathrm{Adm}(v, \mathrm{Tr}_{q\,N(D)}(D); q, 1; p, N(D)^{\,f(D)n_m(D)(\varrho(D)+1)}),$$
$$v(t') = \bigotimes_{i \le \varrho(D)} (\mathrm{v}_D(t')_{2i} \otimes \mathrm{v}_D(t')_{2i+1}).$$

Proof. Factor by factor: $\tau_D(\mathrm{v}_D(t).)_i$ is a sum, over at most $N(D)^{f(D)n_m(D)}$ vectors y, of terms with coefficient 1, and each term is a root of unity times $\varrho_f(t_1)\mathrm{vac} \otimes \varrho_f(t_2)\mathrm{vac}$ with t_1, t_2 the sums of the entries of t and of the translations by $\mp y/N(D)$, since Heisenberg operators compose up to values of the additive character. These translations live at the places above $N(D)$, so the new tuple is admissible for $qN(D)$. Tensoring the $\varrho(D)+1$ factors multiplies the sizes. □

LEAN `Data.isAdmissibleComb_reducedVacuum`

Proposition 9.5 (an invariant combination of reduced vacua is the chain of a good datum)**.** *In Setting 1.1 let ϑ be a twist of D and let w be a tensor in the product of the paired data spaces of the $\varrho(D)+1$ pairs of definite lifts. Assume that*

$$\mathsf{w} \in \mathrm{Adm}(\mathrm{rv}_D(\cdot), \mathrm{Tr}_{\mathrm{n}(\vartheta)}(D); \mathrm{n}(\vartheta), 1; Q(\vartheta) = \emptyset, \mathrm{cut}(D)^{\,2m} \cdot \mathrm{cut}(D)^{\,2\varrho(D)+2}),$$

and that for every tuple $b = (b_j)$ with $b_j \in K_j^{\mathrm{col}}(D)$ and $b_{2\varrho(D)+2} = 1$ the tensor w is fixed by the operator

$$\bigotimes_{i \le \varrho(D)} \omega(b_{2i}, b_{2i+1}) \otimes \omega(b_{2i+1}, b_{2i+2}).$$

Then there is a finitely supported $\Psi\colon \mathrm{Tr}(D) \to \mathbb{C}$ that is a good datum for ϑ and such that for every $\varphi \in \mathrm{St}_0(D)$

$$\mathrm{C}_{D,\vartheta}^{[\varrho(D)+1]}(\mathsf{w})(\varphi) = \mathrm{C}_{D,\vartheta}^{(m)}[\Psi](\varphi),$$

the left side being the chain of pairs extended linearly to tensors.

Proof. Substitute Lemma 9.4 into the combination w: this gives a finitely supported Ψ on $\mathrm{Tr}_{\mathrm{n}(\vartheta)N(D)}(D)$ with values in $O^{(\mathrm{n}(\vartheta))}$ and $\mathsf{w} = \sum_t \Psi(t) \bigotimes_i (\mathrm{v}_D(t)_{2i} \otimes \mathrm{v}_D(t)_{2i+1})$; if $Q(\vartheta) = \emptyset$ its size is at most the product of the two sizes, which the comparisons of the data bound by $\exp(x^{60})$. This is condition (i) of Definition 2.15. The chain of pairs of a pure tensor of pairs is the chain of the single data, so $\mathrm{C}_{D,\vartheta}^{[\varrho(D)+1]}(\mathsf{w}) = \mathrm{C}_{D,\vartheta}^{(m)}[\Psi]$, because $m = 2(\varrho(D)+1)$. Joint invariance (ii): regrouping the tensor of the m single data into pairs carries the joint action of a tuple b to the action in the hypothesis,

which fixes w. Condition (iii): let R be the endomorphism of the tensor product of the paired data spaces that is, on the factor of the pair i, the projection $\mathsf{P}_\Pi \otimes \mathsf{P}_\Pi$ followed by the translate sum of that pair (Definition 2.14); on a pure tensor of single data $s = (s_j)_{j<m}$ it gives the tensor of the pair translates $\tau_D(\mathsf{P}_\Pi s)_i$, $i \le \varrho(D)$. By Lemma 9.3, R fixes the reduced vacuum of every $t \in \mathrm{Tr}_{\mathrm{n}(\vartheta)}(D)$, hence w. Applying R to $\mathsf{w} = \sum_t \Psi(t) \bigotimes_i (\mathrm{v}_D(t)_{2i} \otimes \mathrm{v}_D(t)_{2i+1})$ and then the chain of pairs gives (iii). □

LEAN `Data.exists_isGoodDatum_of_invariant`

10 Proof of the seesaw identity

Proof of Theorem A. The constants. Let C_{v} be the constant of Proposition 9.2. Let R and the constants C_{t} be as in Inputs 2(d) (the last stage). For every tuple ξ of real points let $\mathsf{t}(\xi)$ be the functional of Proposition 5.2 for the pair index $i = \varrho(D)$, the grading $\mathcal{Y}_{\mathrm{last}}(D)$ of $Y_m(D)$, the last arrow pair, whose finite evaluation is $\mathrm{ev}_{D,\varrho(D)}$ by definition, and the trivial real point. Apply Theorem B with $j = m = 2\varrho(D) + 2$, the grading $\mathcal{Y}_{\mathrm{last}}(D)$, whose string has length 0, and the function $\mathsf{a}(\xi) = C_{\mathrm{t}(\xi)}$; let C_{u} be the constant it gives. Put

$$c_D = \Big(\frac{C_{\mathrm{u}}\, C_{\mathrm{v}}}{\mathrm{cut}(D)^{\,2m}} \Big)^{-1} \text{ if this quotient is not zero, and } c_D = 1 \text{ otherwise.}$$

The datum. Fix a twist ϑ. Let M be the tensor product of the paired data spaces and

$$S(q) = \mathrm{ed}_{\varrho(D)}(D, \vartheta; q^\circ) \otimes \ldots \otimes \mathrm{ed}_0(D, \vartheta; q^\circ),$$

where q° is the tuple of the chosen representatives of the cosets q; let w be the vector of Theorem B. By Theorem B(i), w is an admissible combination of the values $S(\text{cosets of } y)$, y integral away from $\mathrm{n}(\vartheta)$, with denominator 1 and size $\mathrm{cut}(D)^{\,m}$; by Lemma 5.1(iii) these values are the tensors of Proposition 9.2. Substituting, w is an admissible combination of the vectors $C_{\mathrm{v}}\mathrm{rv}_D(t)$, $t \in \mathrm{Tr}_{\mathrm{n}(\vartheta)}(D)$, with denominator $\mathrm{cut}(D)^{\,2m}$; clearing the constant and the denominator (Inputs 2(f)), the vector $\mathsf{w}^\star = c_D\, C_{\mathrm{u}}\, \mathsf{w}$ is an admissible combination of the reduced vacua themselves with denominator 1 and size $\mathrm{cut}(D)^{\,2m} \cdot \mathrm{cut}(D)^{\,m}$. It is invariant as Proposition 9.5 requires: for a tuple b with $b_j \in K_j^{\mathrm{col}}(D)$ and $b_m = 1$, the operator $\bigotimes_i \omega(b_{2i}, b_{2i+1}) \otimes \omega(b_{2i+1}, b_{2i+2})$ sends $S(q)$ to S at the tuple moved by the images of the b_j under the inclusions $i_{y_j(D),f}$, because the finite evaluation of an arrow pair commutes with the finite points of the three definite groups (*equivariance of the finite evaluation*, Inputs 2(f)); so Theorem B(ii) applies. Proposition 9.5 gives a good datum Ψ with $\mathrm{C}^{[\varrho(D)+1]}_{D,\vartheta}(\mathsf{w}^\star) = \mathrm{C}^{(m)}_{D,\vartheta}[\Psi]$.

The identity. By the criterion (1) of the last stage it suffices to show, for $\varphi \in \mathrm{Col}^{\mathrm{ram}}(D)$,

$$\mathcal{L}^{(m)}(D, \vartheta)(\mathrm{P}_D(c_D\, \varphi)) = R(\mathrm{C}^{(m)}_{D,\vartheta}[\Psi](\varphi)),$$

and for this to pair both sides with an arbitrary $\Xi \in \mathcal{F}_m(D)$. Apply Theorem B(iii) to the form $z = \overline{\Xi}$, the column φ and the linear form

$$L(\mathsf{w}') = \langle \Xi, R(\mathrm{C}^{[\varrho(D)+1]}_{D,\vartheta}(\mathsf{w}')(\varphi)) \rangle.$$

Its hypothesis: for ξ and y with $y_m = 1$ and $y_0 \in K_D^{\mathrm{ch}}(Y_0(D))$, Proposition 5.2 says that the function of stage m on $\mathcal{Y}_{\mathrm{last}}(D)$ is, on the image of $i_{y_{\mathrm{last}}(D)}$, the coefficient at $\mathsf{t}(\xi)$, on the block diagonal elements, of

$$\psi = \mathrm{C}_{D,\vartheta}^{[\varrho(D)+1]}(\mathrm{ed}.(D,\vartheta;y))(\varphi);$$

by (2) of the last stage its integral against $\overline{\Xi}$ is

$$C_{\mathsf{t}(\xi)}\langle \Xi, R\psi\rangle = \mathsf{a}(\xi)\, L(S(\text{cosets of } y)),$$

again by Lemma 5.1(iii). The conclusion of Theorem B(iii) is

$$\langle \Xi, \mathcal{L}^{(m)}(D,\vartheta)(\mathrm{P}_D\varphi)\rangle = C_{\mathrm{u}} \cdot \langle \Xi, R(\mathrm{C}_{D,\vartheta}^{[\varrho(D)+1]}(\mathsf{w})(\varphi))\rangle.$$

Multiplying by c_D and using linearity in the tensor gives the pairing of Ξ with

$$R(\mathrm{C}_{D,\vartheta}^{[\varrho(D)+1]}(\mathsf{w}^\star)(\varphi)) = R(\mathrm{C}_{D,\vartheta}^{(m)}[\Psi](\varphi)).$$

As Ξ is arbitrary, the two forms agree, and (1) of the last stage gives the theorem. The number c_D was fixed before ϑ and φ. □

11 Where the results are used

Theorem A is used once, in the proof of Theorem A of the write-up (*short forms*, unit *Endgame*): its constant c_D is the constant in the Poincaré maps $\mathrm{pr}_D(\gamma) \circ \mathrm{P}_D \circ (c_D\,\cdot)$ from ramified columns to rows: the restriction of this composite to $\mathrm{Col}^{\mathrm{ram}}(D)$ is the Poincaré series $\mathcal{P}_D(\gamma)$ of Setting 2 of the overview, and the "fixed non-zero constant" of that Setting is c_D (in the formal text the map is the composite of the projection, the Poincaré series and the inclusion of the ramified columns scaled by the constant chosen from Theorem A). The roman P_D of this note is the series before the projection and the scaling. For every twist the good datum turns the size and the divisibility of $\iota_{D,\vartheta}$ of such a row into those of $B^{\Psi}_{D,\vartheta}$, which the units *Columns*, *Curve* and *TwistedHecke* estimate. The map $\iota^{\mathrm{lev}}_{D,\vartheta}(\,\cdot\,)$ restricted to the rows is the chain of lifts $\Theta_{D,\vartheta}$ of the overview; Corollary 3.5 and Lemma 3.3 are used by the units *Rows* and *Exchange*, and Proposition 4.1 with the maps of Definition 2.11 by the unit *Filling*, which in turn supplies the last stage (Inputs 2(d)).

12 Notes on the formal text

What kind of seesaw. The identity moves a chain of theta lifts from the tower of indefinite spaces $Y_j(D)$ to the tower of definite spaces $X_j(D)$ sitting inside them, at the price of a Bessel period; the header of the formal file calls it a seesaw identity and names as related work B. Wang (2025), Gomez–Zhu (2014) and Gan–Ichino (2016) for the transfer of Bessel and Fourier–Jacobi periods, and Gross (1999), Hsieh–Namikawa (2015) and X. Zhang (2022) for periods on definite groups as finite sums. Kudla's seesaw principle in the form of the background library (which the catalogue marks as a weaker form) is used in the unit *Exchange*, not here: this unit unfolds.

Shape of the statements. (1) Theorem A is stated for twists, because a good datum is defined for twists; Theorems B and C and all statements about the chain hold for tame characters. (2) In Theorem B the grading $\mathcal{Y}$ is arbitrary with the right string length, and the subtraction in $l = 2\varrho(D) + 1 - j$ is truncated; the proof uses it for $\mathcal{Y}_j(D)$ and, at $j = m$, for $\mathcal{Y}_{\mathrm{last}}(D)$. The integrability in (iii) is a hypothesis *inside* the hypothesis: the formal text never has to prove that the function of stage $j+1$ times z is integrable, because the unfolding step provides it. (3) The constant c_D is Mathlib's normalising unit of $C_{\mathrm{u}}C_{\mathrm{v}}/\mathrm{cut}(D)^{2m}$, which is 1 when the quotient vanishes; the formal text does not show that the quotient is non-zero and does not need it. (4) The bound $\exp(x^{60})$ in the definition of a good datum is asked only for $Q(\vartheta) = \emptyset$, and so are all size clauses in this note. (5) Lemma 3.3(ii) is stated for every commutative ring, with the cardinality of an infinite set counted as 0. (6) The grading $\mathcal{Y}_{\mathrm{last}}(D)$ is defined for every number M with a proof that $m = M$, and the functions of stage $j+1$ are defined for an arbitrary grading of $Y_{j+1}(D)$, which enters only through the constant term. (7) The groups of a hermitian space with frame depend on less than the space: $G_f(V)$ on the index set, $G(V)$ on the signs; the notation of this note records the space whose frame gives the rational structure.

Arguments in the census that Lean does not take. The census of the write-up reads arguments from the text. For the following declarations it lists section variables that the statement binds again, or that occur only as the name of a field: the tame character, the column and the tuple of finite points in Proposition 5.2 (bound inside the statement; Lean takes only ξ); a twist in Proposition 9.2 (the statement quantifies over tame characters); a Boolean named like the constant of a grading in Lemma 6.7(iii); a group, a subgroup and a set of cosets in Propositions 7.2 and 7.3; the two subgroups of Definition 2.20, listed twice. The census ends the statement of Theorem C at its first *let* and so lists only the stage and its bound; the theorem is stated here in full, from the source. For five definitions whose type ends in a linear map or a function ($\mathcal{L}_j(D,\vartheta)(\,\cdot\,)$, $\mathcal{L}^{(j)}(D,\vartheta)(\,\cdot\,)$, $\iota^{\mathrm{lev}}_{D,\vartheta}(\,\cdot\,)$, $\mathrm{lch}_{D,\vartheta}(\cdot)$, $\mathrm{bl}_j(\cdot)$) the census counts the argument of that map as an argument of the definition; the notation shows it. Unused hypotheses were not determined: no Lean was run for this note.

The second reading. A second reader compared the member texts of the whole unit and a sample of the proof steps with the Lean source, after the dossier was made. Where her reading and the dossier differ, this note follows her, having checked each point in the source: one scalar c_D for the datum, chosen before the twist, and a restriction that acts on the definite chain only, the indefinite chain being paired with a test form directly (proof of Theorem A); in Proposition 7.3 the average over the finite Bessel group is taken for every coset of non-zero multiplicity, the multiplicity and not the indicator of the cut being invariant under the whole group; the common weight of the translations is π_g, and the two blocks of a combined vector carry the two conjugate weights (Propositions 9.1 and 9.2); Proposition 9.2 holds for tame characters; the normal form of the Poincaré series is stated with the coordinates of general filling data, the translation by the lattice scale entering only through cc_D; and the constant of Theorem A keeps the zero case of the normalisation.

What the final theorems use. The reader's dossier sets nothing of the unit aside. Of this note, the instance that the index sets $\underline{Y}_j(D)$ are non-empty is used only implicitly.

How this note was written. From the reader's dossier of the unit, after its program check passed, and from the Lean source. Of the 32 structured proofs that belong to this note all were read. In the Lean text I read completely the files of the theorem (all three proofs line by line), of the chain and the gradings, of the stage functions, of the adapted bases, of the two lattice steps, of the standard lattice, of the cuts, of the Poincaré series at Bessel points and of the good datum, and the six lemmas on valuations and levels; among them the four proofs that the reader asked to sample first (Propositions 9.2, 6.6, 4.3 and 7.3). There the structure, the order of the steps and every cited lemma agree with the dossier; the long chains of rewriting and of automated case analysis at the end of these four proofs, and of Propositions 6.2, 6.5 and 9.1, were not run, and the note describes their effect from the terms involved rather than reproducing them. The definitions recalled from the background library and from other units (spaces with frame, gradings, Bessel groups, generic functions, the unfolding step, arrows, chains, good data, filling data) were read in the Lean source; the Inputs are stated as their Lean statements read, the last stage, the unfolding of Poincaré series, the unfolding step and the transposition of lift and descent after the source, the others after the dossier. The proofs here follow the formal ones; they are shorter where the formal text spends lines on coercions, on measurability and on the choice of representatives. The program check of the unit's dossier covered 503 leaf steps of 83 proofs.

Revision. After an independent referee's report the note was revised. The Inputs were completed: the discrete-series input on which every lift rests, four further facts of the library and three of the unit *Filling* are now listed, with their status in the catalogue; Inputs 2(e) is quoted with the adele that sets the weight of the translates, read again in the Lean source, so that step (e) of Proposition 6.8 follows from it. The proofs of Lemma 6.4, of Propositions 6.5, 6.6 and 9.1, of the last step of Proposition 4.4 and of the first hypothesis in the proof of Theorem C were completed. The two boxes of Inputs have their own numbers, Theorem B is stated before Theorem C, the constant of Theorem A is written c_D, and the objects of the library carry the names and the arguments that the other notes of the unit give them.

The statement of the theorem, as the artifact has it:

```
lemma seesaw : ∃ c : ℂˣ, ∀ θ, ∃ Ψ, IsGoodDatum θ Ψ ∧ ∀ φ,
  ι θ (D.poincare ((c.1 • D.ramifiedColumns.subtype) φ)) = Bμ θ Ψ φ
```

Notation

$P = (N_0, d)$, K parameters; the field $\mathbb{Q}(\sqrt{-d})$

D admissible data for P, with components x, x_1, b (scales), μ (exponent), m (number of lifts), r (rank), g_0, g_1 (primes), π_g

$E(D)$, $f(D)$, $g(D)$, $t(D)$, $n_j(D)$ the CM field; the number of its infinite places; $g_0 g_1$; $5r$; the rank of stage j

$\mathbf{j}$, α, υ, $\varpi(P, \mu)$ Weil data: an element of trace zero, an idele, the splitting character; the generator of the different of $E(D)$

$\varrho(D)$ $m/2 - 1$

$\bar{\pi}_g(D)$, $\hat{\pi}_g(D)$, $\hat{\pi}_N(D)$ the conjugate of π_g in $E(D)$; an idele generating its ideal; the principal idele of $\pi_N(D)$ (the last two written as in the note of the unit *Trace*)

$N(D)$, $\pi_N(D)$, $\Pi(D)$ the level prime; an integer of norm $N(D)$; the places dividing it

ϑ, $Q(\vartheta)$, ψ_ϑ, $\mathrm{n}(\vartheta)$ a tame character; its places; its tame part; the product of the norms of its places

$\omega_{D,w}$, $\mu_{D,j}(\vartheta)$, $\psi_{D,j}(\vartheta)$ residue characters at chosen places; the characters of the lifts; their tame parts

$\underline{X}_j(D)$, $\underline{Y}_j(D)$, $X_j(D)$, $Y_j(D)$ index sets; the definite and the graded hermitian spaces

$\mathsf{G}(D)$, $e_0(D)$, γ the finite group; the good idempotent; an element of $\mathsf{G}(D)$

E, $\mathbb{A}$, $\mathbb{A}_f$, $\hat{\mathcal{O}}$, $\mathcal{O}_w$ a CM field; adeles; finite adeles; their integers; local integers

w, v, $\overline{w}$, $\mathbb{F}_w$, $\mathrm{N}\, w$, ord_w finite places; conjugate; residue field; norm; order

V, V', W, I, J_V, x_V, $x_{V,f}$ hermitian spaces with frame; index set; Gram matrix; frame and its finite part (written as in the note *Two consecutive theta lifts*)

$G(V)$, $G_\infty(V)$, $G_f(V)$, $\Gamma(V)$ adelic, real, finite and rational points

$K_0(V)$, $K_w(V)$, $K^{(n)}(V)$, $K_D^{\mathrm{ch}}(V)$ lattice stabiliser; its part at w; points integral away from n; principal level at the chosen places

$\mathcal{Y}$, $\mathcal{Y}'$, e_y, $\mathfrak{c}(\mathcal{Y})$, N, X, l gradings; bijection; constant; norm; set; string length

z_a, gr, a, a' string vectors; grade; string indices

$U(\mathcal{Y})$, $B(\mathcal{Y})$, $B_f(\mathcal{Y})$, $\Gamma_B(\mathcal{Y})$ unipotent and Bessel groups; finite part; rational points

i_y, $i_{y,f}$ the inclusion of the group of X

ψ_E, sh_y the standard additive character; the shift matrix

$\mathcal{S}(W)$, $\mathcal{W}_f(W)$, $\varrho(y)$, $\varrho_f(y)$, ω, ω_ν^{pr}, θ theta data; finite part; Heisenberg operators; Weil representation; twisted pair action; theta functional

ν, Φ, $v \otimes f$, $\boxtimes$ a character; a datum; integrated datum; arrow product

$T_{y,y'}$, ct, unf the string map; constant term at the string map; unfolded function

$\mathcal{Y}_j(D)$, $\mathcal{Y}_{\mathrm{last}}(D)$ the gradings of the spaces $Y_j(D)$

$\mathrm{in}_{D,j}$, $\mathrm{bl}_j(i)$, R_0, T_0 block inclusion; block number; sets of blocks

$\mathcal{J}_j(D, \vartheta)$, $\psi_j^{\uparrow}(D, \vartheta)$, $\mathcal{K}_j(D, \vartheta)$, $\Upsilon_j(D, \vartheta)$ level, tame part, kernel and finite datum of lift $j+1$

$\mathcal{F}_j(D)$, $\mathfrak{d}_j(D,\vartheta)$, $\mathcal{L}_j(D,\vartheta)(F)$, $\mathcal{L}^{(j)}(D,\vartheta)(F)$ forms; datum; one lift; j lifts

$\iota_{D,\vartheta}$, $\iota^{\mathrm{lev}}_{D,\vartheta}(F)$, $\mathsf{P}_{\mathrm{last}}(D,\vartheta)$, $\mathrm{lch}_{D,\vartheta}(\kappa)$, $\mathrm{lift}_{D,\vartheta}(\gamma)$ the chain of m lifts; with its level; the level group and its character; a lift of γ

S, g_{S}, ϖ_{S}, K_{S}, $K^{\mathrm{pr}}_{\mathsf{S}}$, X_0, η filling data and their components; a central element

$\mathrm{P}_{\mathsf{S}}(\phi,\Delta)$, cb_a, cc_{S}, A, W, $\sigma(u)$ Poincaré series; cut-off Bessel functions; column coordinates; change of coordinates; Bessel vector; simple root sum

$\mathrm{Col}(D)$, $\mathrm{Col}^{\mathrm{ram}}(D)$, cc_D, P_D, $\mathrm{pr}_D(\gamma)$ columns; ramified columns; their coordinates; Poincaré series; projection to rows

$O^{(n)}$, $\mathrm{Adm}(v,\mathcal{J};n,d;p,B)$ numbers integral away from n; admissible combinations

ℓ, $\jmath$, σ a prime; a ring homomorphism $\mathbb{C}\to\mathbb{C}_\ell$; an automorphism of $\mathbb{C}$

$K^{\mathrm{col}}_j(D)$, $\mathrm{St}_j(D)$, $z_w(D)$ level and forms of stage j; the central translation at w

$\mathrm{Tr}(D)$, $\mathrm{Tr}_q(D)$, $\mathrm{v}_D(t)_j$ translations; admissible ones; translated vacua

$\mathrm{C}^{(j)}_{D,\vartheta}(\Phi)$, $\mathrm{C}^{[p]}_{D,\vartheta}(\Phi)$, $\mathrm{C}^{(j)}_{D,\vartheta}[\Psi]$ chains of definite lifts: single, paired, combined

res_D, $B^{\Psi}_{D,\vartheta}$, Ψ restriction to $Y_m(D)$; the definite side; a good datum

$\underline{X}^{\circ}_j(D)$, $\mathsf{T}_{N,\Sigma}(I,I',I'')$, $\tau_D(v)_i$, $\mathrm{rv}_D(t)$ $\underline{X}_j(D)$ without its point; translate sum of three index sets, a set of places and a prime; pair translates of a family v; reduced vacuum

P_Π, R, I', I'' projection at $\Pi(D)$; an endomorphism (Proposition 9.5); index sets

φ, ψ, ξ, y, $\mathfrak{P}^{(j)}_{D,\vartheta,\varphi}[\xi,y;\mathcal{Y}]$ columns; tuples of real and finite points; stage functions

$\mathrm{ev}_{D,i}$, $\mathrm{cut}(D)$, $\Upsilon_j(D,\vartheta;y)$, $\mathrm{ed}_i(D,\vartheta;y)$ finite evaluation of a pair; the cut bound; moved and evaluated data

$\mathrm{fl}_e(i)$, b, β, k, d flag order; adapted basis; string diagonal; auxiliary matrices

$\mathfrak{a}$, $\mathfrak{b}$, $\mathfrak{a}(D)$, $u_j(D)$, ϵ_a, Λ, π, Σ ideles; the idele and the scale of the data; reference factors; graded lattice basis; an idele of norm N; a split set of places

H, S, A, J, T, t, H_0, K, W, C a group, subgroups, a set of cosets, a coset; a subgroup, a compact set, a set of points, representatives

$\mathrm{mult}_{S,A}(T;t)$ multiplicity of a cut

C, C_i, C_{t}, C_{u}, C_{v}, c_D constants; the constant of Theorem A

M, L, Ω, a, b, w, $\mathsf{w}^\star$, q, q' a vector space, a linear form, an endomorphism; functions; vectors of M; tuples of cosets

t, $\langle\mathsf{t},\psi\rangle$, R, Ξ, z, $z^\flat$, F a functional; a coefficient; the last-stage map; forms; functions

g, h, h_0, k, u, ς, p, n, i, j, e, f points, integral points, unipotent and Bessel elements; natural numbers and indices; a bijection; a datum

δ, δ_a, λ_0, M, W, ε, κ a norm-one idele; exponents; an integral vector; matrices; a unit with $\overline{\varepsilon}\varepsilon=-1$; a family of weights

e, u_0, g, s, S_0, $\varkappa$, $\mathfrak{p}_w$, $\mathrm{M}_I(\mathcal{O}_w)$ in the Inputs and in single proofs: an integral adele, a projected vector, a representative, a map of parameters, a stabiliser, a number, the maximal ideal at w, a matrix ring

letters with two meanings b: the third scale of D (Setting 1.1 only), an adapted basis (Section 6), and with an index a member of a tuple of level elements; d: the prime of P, and a denominator of an admissible combination; t: a coset, and a tuple of translations in $\mathrm{Tr}(D)$; T: a set of cosets, and with two gradings as indices the string map; x: the first scale of D, and a point or a parameter; ϱ: the Heisenberg operators, and with D the number $\varrho(D)$; P: the parameters, the roman P_D is the Poincaré series and the fraktur one the stage functions; w: a finite place, the sans-serif w a vector; ν: a character, and an index or exponent

$\Theta_{D,\vartheta}$ the chain of lifts on the rows, as in the overview

$\mathfrak{X}$, $\mathfrak{m}$, $\mathfrak{m}_1$, s, Δ, Γ, ϕ, Q, Q_0, U, B, G, Y, Z, O level places; moduli; a datum; a subgroup; coefficients; sets of places and of planes; letters occurring only inside the names above

READBACK NOTE 22

Two consecutive theta lifts: admissible combinations, arrow pairs and zero terms

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The seesaw identity of Chapter V is proved by unfolding a chain of theta lifts two lifts at a time. This note supplies that two-lift step and its arithmetic bookkeeping. First, a calculus of *admissible combinations*: finite linear combinations whose coefficients are integral away from a given integer, up to a denominator, and bounded at every conjugate. Second, for three hermitian spaces graded by strings of lengths l, $l-1$, $l-2$, an *arrow pair*: a splitting of the space of homomorphisms that carries two consecutive lifts at once; its zero term intertwines the Weil actions, so that the period of a generic function against two consecutive constant terms is a matrix coefficient of two definite theta lifts. Third, the finite part of that zero term sends translated vacua to admissible combinations of Gauss-sum translates of pairs of translated vacua.

What this note is. The artifact grh-compact is a body of Lean code whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. Its authors report that it compiles and that Lean's kernel accepts these theorems from the three standard axioms; the record of checks of this write-up says who replayed what. That is a fact about a formal text: no mathematician has read the argument through, and the result is a *claim*. This note treats one part of one unit of the argument (the folder of the seesaw identity): 57 of its 312 declarations, those of eight files; the other declarations are treated in the notes on the seesaw identity, on the Gauss-sum operator and on the characters and index sets of the data. Every statement below was compared, argument by argument, with its Lean statement, and every proof is written out from the Inputs, except that two statements proved in the formal text by one automatic step are only described (Lemma 3.2, parts (c) and (d)). What is taken for granted is stated as Inputs 1 to 7 with its owner: the construction of the Weil representation, its mixed model and the unfolding of Bessel periods come from the background library of the artifact, which this write-up quotes and does not read. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 98 declarations.

1 The statements

The objects are defined in Section 2; the four statements cite its Settings. Throughout, a *proposition* p is a statement that may or may not hold: it switches the size bounds on.

Theorem A (calculus of admissible combinations). Let $\mathcal{X}$, $\mathcal{X}'$ be sets, Z a complex vector space, $v\colon \mathcal{X} \to Z$ and $v'\colon \mathcal{X}' \to Z$ families of vectors, $A \subseteq \mathcal{X}$ and $A' \subseteq \mathcal{X}'$, n and d natural numbers, p a proposition, B a real number and $z \in Z$ with $z \in \mathrm{Adm}(v, A; n, d; p, B)$ (Definition 2.8).
(i) Substitution. Let d', d'' be natural numbers and B', C real numbers. Suppose that $v(x) \in \mathrm{Adm}(v', A'; n, d'; p, B')$ for every $x \in A$, that $d \cdot d'$ divides d'', and that p implies $B \cdot |B'| \le C$. Then $z \in \mathrm{Adm}(v', A'; n, d''; p, C)$.
(ii) Integrality. Let ℓ be a prime number that does not divide n, let $\jmath\colon \mathbb{C} \to \mathbb{C}_\ell$ be a ring homomorphism, $O_\jmath$ the ring of the complex numbers w with $|\jmath(w)|_\ell \le 1$, and M an $O_\jmath$-submodule of Z that contains $v(x)$ for every $x \in A$. Then $d \cdot z \in M$.
(iii) Tensor products. Let n be a natural number and p a proposition. For $j \in \mathbb{N}$ let $\mathcal{X}_j$ be an additive group and A_j a subgroup of it; for $i \in \mathbb{N}$ let F_i be a complex vector space, $v_i\colon \mathcal{X}_{2i} \times \mathcal{X}_{2i+1} \to F_i$ a family and $f_i \in F_i$. Let d, m be natural numbers and B a real number, and suppose $f_i \in \mathrm{Adm}(v_i, A_{2i} \times A_{2i+1}; n, d; p, B)$ for every $i < m$. Let $v_{\otimes m}$ be the family $y \mapsto v_{m-1}(y_{2m-2}, y_{2m-1}) \otimes \cdots \otimes v_0(y_0, y_1)$, indexed by all tuples $y = (y_j)_{j\in\mathbb{N}}$ with $y_j \in \mathcal{X}_j$, and A_* the set of the tuples with $y_j \in A_j$ for all j. Then the pure tensor satisfies

$$f_{m-1} \otimes \cdots \otimes f_0 \in \mathrm{Adm}(v_{\otimes m}, A_*; n, d^m; p, |B|^m).$$

Theorem B (the zero term of an arrow pair is equivariant). In Setting 2.6, let X'' and H be finite index sets and $\mathcal{R} \in \mathrm{Arr}_{X'',H}(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}'')$ an arrow pair (Definition 2.16), with its homomorphism $\mathrm{emb}_{\mathcal{R}}\colon G(\langle X_0\rangle) \to G(\langle X''\rangle)$, its splitting $\Xi^{\mathrm{pr}}(\mathcal{R})$ and its finite evaluation $\mathrm{fev}_{\mathcal{R}}$ (Definition 2.17). Let μ, μ' be characters of $\mathrm{U}(1)(\mathbb{A})$ trivial on $\mathrm{U}(1)(E)$.
(i) For all $g \in G(\langle X\rangle)$, $g' \in G(\langle X'\rangle)$, $k \in G(\langle X_0\rangle)$ and $f \in \mathcal{S}(\mathrm{Hom}(V', V^- \oplus V''))$,

$$\mathrm{ev}_{\Xi^{\mathrm{pr}}(\mathcal{R})}\Big(\omega^{\mathrm{tr}}_{\mu,\mu'}(\imath_{\mathcal{Y}}(g), \imath_{\mathcal{Y}'}(g'), \imath_{\mathcal{Y}''}(k))f\Big) = \omega^{\mathrm{tr}}_{\mu,\mu'}(g, g', \mathrm{emb}_{\mathcal{R}}(k))\ \mathrm{ev}_{\Xi^{\mathrm{pr}}(\mathcal{R})}(f).$$

(ii) Let $g \in G_f(X)$, $g' \in G_f(X')$, $k \in G_f(X_0)$, $k' \in G_f(X'')$ and $x \in G_f(I'')$ be finite points with $\imath^f_{\mathcal{Y}''}(k) = x$ and $\mathrm{emb}_{\mathcal{R}}(1, k) = (1, k')$, and let $\Phi \in \mathcal{W}_f(\mathrm{Hom}(V, V'))$, $\Phi' \in \mathcal{W}_f(\mathrm{Hom}(V', V''))$. Then

$$\begin{aligned}\mathrm{fev}_{\mathcal{R}}\Big(\omega^{\mathrm{pr},f}_{\mu}(\imath^f_{\mathcal{Y}}(g), \imath^f_{\mathcal{Y}'}(g'))\Phi \boxtimes \omega^{\mathrm{pr},f}_{\mu'}(\imath^f_{\mathcal{Y}'}(g'), x)\Phi'\Big)\\ = (\omega^{\mathrm{pr},f}_{\mu}(g, g') \otimes \omega^{\mathrm{pr},f}_{\mu'}(g', k'))\ \mathrm{fev}_{\mathcal{R}}(\Phi \boxtimes \Phi').\end{aligned}$$

Theorem C (two unfolding steps are a double lift). *(i)* In Setting 2.6, let X'' and H be finite index sets and $\mathcal{R} \in \mathrm{Arr}_{X'',H}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'')$. There is $z \in \mathbb{C}$ such that for all characters μ, μ' of $\mathrm{U}(1)(\mathbb{A})$ trivial on $\mathrm{U}(1)(E)$, all data $f \in \mathcal{S}(\mathrm{Hom}(V,V'))$ and $f' \in \mathcal{S}(\mathrm{Hom}(V',V''))$, all $k \in G(\langle X_0\rangle)$, all functions $P\colon G(V) \to \mathbb{C}$ and all $h \in G(V)$: if P is generic for $\mathcal{Y}$, then

$$\begin{aligned}&\int_{[B(\mathcal{Y}')]} \int_{[B(\mathcal{Y})]} P(gh)\ \mathrm{ct}^{\mu}_{\mathcal{Y},\mathcal{Y}'}(f)(g,r)\ \mathrm{ct}^{\mu'}_{\mathcal{Y}',\mathcal{Y}''}(f')(r,\imath_{\mathcal{Y}''}(k))\,dg\,dr\\ &\quad= \int_{[G(\langle X\rangle)]} P(\imath_{\mathcal{Y}}(g)h)\Big(z \int_{[G(\langle X'\rangle)]} \theta(\omega^{\mathrm{tr}}_{\mu,\mu'}(g,r,\mathrm{emb}_{\mathcal{R}}(k))f_{\mathcal{R}})\,dr\Big)dg,\\ &\qquad\text{where } f_{\mathcal{R}} = \mathrm{ev}_{\Xi^{\mathrm{pr}}(\mathcal{R})}(\varrho(\mathbf{T}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}''))(f\boxtimes f')).\end{aligned}$$

Here $\varrho(\mathbf{T}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}''))$ is the Heisenberg operator of $\mathrm{Hom}(V',V^-\oplus V'')$ at the frame coordinates of the stacked string map (Definition 2.15), and θ is the theta functional of $\mathrm{Hom}(\langle X'\rangle,\langle X\rangle^-\oplus\langle X''\rangle)$.
(ii) Let E be a CM field with Weil data, X, X', X_0 finite index sets, $\varkappa$ a weight and e, e', e'' determinant exponents, U a set, and for $o \in U$ let μ_o, μ'_o be characters of $\mathrm{U}(1)(\mathbb{A})$ trivial on $\mathrm{U}(1)(E)$ and

$$\begin{aligned}&\mathcal{L}_o\colon \mathcal{W}_f(\mathrm{Hom}(\langle X\rangle,\langle X'\rangle)) \to \mathrm{Hom}_{\mathbb{C}}(\mathcal{A}(X;\varkappa,e),\mathcal{A}(X';\varkappa,e')),\\ &\mathcal{L}'_o\colon \mathcal{W}_f(\mathrm{Hom}(\langle X'\rangle,\langle X_0\rangle)) \to \mathrm{Hom}_{\mathbb{C}}(\mathcal{A}(X';\varkappa,e'),\mathcal{A}(X_0;\varkappa,e''))\end{aligned}$$

linear maps such that $(\mathcal{L}_o)_o$ is a family of theta lifts for $(\mu_o)_o$ and $(\mathcal{L}'_o)_o$ a family of theta lifts for $(\mu'_o)_o$ (Input 5). Let u be a real datum of $\mathrm{Hom}(\langle X'\rangle,\langle X\rangle^-\oplus\langle X_0\rangle)$ and t a linear functional on the vectors of weight $\varkappa$ for X. Let $\mathcal{L}''_o$ be the linear map on $\mathcal{W}_f(\mathrm{Hom}(\langle X\rangle,\langle X'\rangle))\otimes\mathcal{W}_f(\mathrm{Hom}(\langle X'\rangle,\langle X_0\rangle))$ with $\mathcal{L}''_o(\Phi\otimes\Phi') = \mathcal{L}'_o(\Phi')\circ\mathcal{L}_o(\Phi)$. Then there is a linear functional t'' on the vectors of weight $\varkappa$ for X_0 such that for all $o \in U$, all y in the tensor product, all $\varphi \in \mathcal{A}(X;\varkappa,e)$ and all $g \in G(\langle X_0\rangle)$

$$\begin{aligned}&\int_{[G(\langle X\rangle)]} \mathrm{coef}_t(\varphi)(x) \int_{[G(\langle X'\rangle)]} \theta\Big(\omega^{\mathrm{tr}}_{\mu_o,\mu'_o}(x,r,g)(u\otimes \mathrm{at}(y))\Big)\,dr\,dx\\ &\qquad= \mathrm{coef}_{t''}(\mathcal{L}''_o(y)(\varphi))(g).\end{aligned}$$

Theorem D (the finite evaluation of an arrow pair is admissible). In Setting 2.19, with its index sets X, X'' and its objects N, Σ, π, δ, β, κ, let X', X_0, H be finite index sets and l, l', l'' natural numbers; let V, V', V'' be hermitian spaces over E with index sets I, I', I'' and with gradings: $\mathcal{Y}$ of V with definite part X^+ and a string of length l, $\mathcal{Y}'$ of V' with definite part X'^+ and a string of length l', $\mathcal{Y}''$ of V'' with definite part X_0 and a string of length l'', all of norm N. Let a be a finite idele and u a finite adele with $u\bar{u} = 1$ such that $\mathsf{Lat}(\mathcal{Y}'; a, \pi, u)$, and suppose $\delta = (\bar{\alpha}/\alpha)\cdot(a/\bar{a})$, α the idele of the Weil data. Let $\mathcal{R} \in \mathrm{Arr}_{X''^+, H}(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}'')$ be an arrow pair, with the matrix $\mathrm{inc}_{\mathcal{R}}$ of its zero part (rows $I \sqcup I''$, columns $(H \sqcup H) \sqcup (X^+ \sqcup X''^+)$). Suppose:
(weights) for all $i \in I \sqcup I''$ and $b \in X^+ \sqcup X''^+$, either $\mathrm{inc}_{\mathcal{R}}(i,b) = 0$ or $|\beta^{\langle i\rangle}|_w = |\beta^{\langle b\rangle}\kappa_b|_w$ for every finite place w;
(lattices) for all $r_1, r_2 \in \mathbb{A}_f$ with $r_1 \cdot (a/\bar{a}) = \overline{\epsilon_-}\,\delta$ and $r_2 r_1 = 1$, all c, x such that $\mathsf{Nb}_{\pi,\delta}(c; x)$, and the vector $v = \mathrm{inc}_{\mathcal{R}} \cdot ((0,\, r_1 u c),\ (r_1\kappa_b x_b)_{b\in X^+},\ (\kappa_b x_b)_{b\in X''^+})$, whose coordinates on the first copy of H are 0 and on the second copy all equal to $r_1 uc$: all entries of $x^{-1}_{V',f}(r_2\, v|_I)$ and of $x^{-1}_{V'',f}(v|_{I''})$ lie in $\hat{\mathcal{O}}$.
Then $\mathsf{AdmEv}_{N,\Sigma,\beta}(\mathrm{fev}_{\mathcal{R}}; \beta^{\langle\cdot\rangle})$: the finite evaluation of $\mathcal{R}$ is an admissible evaluation for (N, Σ, β) (Definition 2.21, with the index sets X, X'^+, X'').

The four theorems are used in the note on the seesaw identity. Theorem A is the bookkeeping of every denominator and every size there; Theorem C, applied once for each pair of consecutive lifts, turns the function left after an even number of unfoldings into a matrix coefficient of a chain of pairs of definite lifts; Theorem B makes the resulting data invariant under the levels; Theorem D, with Theorem A(iii), expresses these data through translated vacua with controlled denominators. The transfer of a Bessel or Fourier–Jacobi period under one theta lift is known; the file of the seesaw theorem names as related work B. Wang (2025), Gomez–Zhu (2014) and Gan–Ichino (2016). The seesaw principle of Kudla, which the background library proves in a weaker form for periods, is not used in this note.

2 The setting

Conventions. In every statement E is a CM field with a CM type (one embedding into $\mathbb{C}$ chosen from each pair of complex conjugate embeddings). The bar is complex conjugation on E, on its adeles $\mathbb{A}$, on the finite adeles $\mathbb{A}_f$ and on the ring $\hat{\mathcal{O}}$ of integral finite adeles; M^* is the conjugate transpose of a matrix. Finite places of E are written w, with conjugate place $\bar{w}$; $|\cdot|_w$ is the absolute value at w, with value e^{-1} at a uniformiser, and u_w is the component at w of a finite adele u. Where a statement says so, E carries *Weil data* (Definition 2.2). All index sets (I, I', I'', I_0, I_1, I_2, X, X', X'', X_0, H) are finite; for an index set X we put $X^+ = X \sqcup \{\mathrm{pt}\}$, and $\{0, \dots, l-1\}$ indexes a *string* of length l. Vectors over $\mathbb{A}_f$ indexed by a product of index sets are also read as matrices. The letters Z, Z', W, F_i denote complex vector spaces, $\mathcal{X}$, $\mathcal{X}'$ sets that index families of vectors, $\mathcal{X}_j$ an additive group. A prime number is ℓ or N; $\jmath\colon \mathbb{C} \to \mathbb{C}_\ell$ is a ring homomorphism and $O_\jmath$ the ring of the $w \in \mathbb{C}$ with $|\jmath(w)|_\ell \le 1$; σ runs over the field automorphisms of $\mathbb{C}$. In Section 4, R and S are commutative rings and R has an involution, written as a bar. A hermitian space

V has an index set and signs (Definition 2.1); gradings are written y, y', y'', with strings of lengths l, l', l'' and norm N.

Vocabulary of the background library. The next five definitions recall objects that the artifact constructs in its background library. They are not declarations of this unit; we state what the proofs use, and quote their properties as Inputs 1 to 7.

Definition 2.1 (hermitian spaces and their groups; recalled)**.** A *hermitian space* V over E consists of a finite index set I, *signs* $I \to \{\pm 1\}$, a hermitian matrix $J_V \in M_I(E)$ and a *frame* $x_V \in \mathrm{GL}_I(\mathbb{A})$ such that $x_V^* J_V x_V$ is the diagonal matrix of the signs at every infinite place and the identity at every finite place; $x_{V,f}$ is the finite part of x_V. So $x_{V,f}\hat{\mathcal{O}}^I$ is a self-dual lattice for J_V. The adelic unitary group is $G(V) = G_\infty(V) \times G_f(I)$, where $G_\infty(V)$ is the product over the infinite places of the unitary groups of the signs and $G_f(I) = \{g \in \mathrm{GL}_I(\mathbb{A}_f) : g^* g = 1\}$; an element $g = (g_\infty, g_f)$ has the *matrix in rational coordinates* $x_V g x_V^{-1}$, which is unitary for J_V. The *rational points* $\Gamma(V)$ are the g whose matrix in rational coordinates has entries in E, and $[G(V)] = \Gamma(V)\backslash G(V)$ carries the invariant measure of the library (a probability measure when V is definite). The *standard space* $\langle X \rangle$ on an index set X has all signs $+1$, $J = 1$ and frame 1; it is definite. For hermitian spaces V, V' (index sets I, I'), $\mathrm{Hom}(V, V')$ is the hermitian space with index set $I' \times I$, matrix $J_{V'} \otimes (J_V^{-1})^{\mathsf{T}}$ and frame $x_{V'} \otimes (x_V^{-1})^{\mathsf{T}}$; a pair $(g, g') \in G(V) \times G(V')$ acts on it by $y \mapsto g' y g^{-1}$. $V \oplus V'$ is the orthogonal sum, $\mathbb{H}^H$ the hyperbolic space with index set $H \sqcup H$ and matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, and $\mathbb{H}^H \oplus V$ their sum. An adelic matrix $y \colon V \to V'$ *in rational coordinates* is an $I' \times I$ matrix over $\mathbb{A}$; its *frame coordinates* are $x_{V'}^{-1} y x_V$, and its *adjoint* is $y^\dagger = J_V^{-1} y^* J_{V'}$.

Definition 2.2 (Weil data, spaces of data, the Weil representation; recalled)**.** *Weil data* for E are: the condition that E is stably unramified in the sense of the library, which provides a unit ϵ_- of $\hat{\mathcal{O}}$ with $\overline{\epsilon_-}\,\epsilon_- = -1$; an element $\mathbf{j} \in E$ with $\bar{\mathbf{j}} = -\mathbf{j}$; a finite idele α such that $\mathbf{j}\alpha\bar{\alpha}$ generates the inverse different at every finite place; and a splitting character v, a Hecke character of E whose restriction to the norm-one ideles is again written v. For a hermitian space V over such an E, with index set I, the library constructs: a Banach space $\mathcal{S}(V)$ of *data*, which are functions on $\mathbb{A}^I$; *Heisenberg operators* $\varrho_V(y)$ on it, for $y \in \mathbb{A}^I$; the *Weil representation* ω_V of $G(V)$ on it; the *theta functional* $\theta_V \colon \mathcal{S}(V) \to \mathbb{C}$, invariant under $\Gamma(V)$, with $f(y) = \theta_V(\varrho_V(y) f)$ for every datum f and $y \in \mathbb{A}^I$; the *vacuum* $\mathrm{vac}_V \in \mathcal{S}(V)$; and a space $\mathcal{F}(V)$ of *real data* (a Fock space) with its *polynomial vectors* v_Q, Q a complex polynomial, and a bounded bilinear map $\mathcal{F}(V) \times \mathcal{S}(V) \to \mathcal{S}(V)$, $(v, f) \mapsto v \otimes f$. The *finite Heisenberg operator* of $x \in \mathbb{A}_f^I$ is $\varrho_{f,V}(x)$, a root of unity times ϱ_V at the adelic vector with real part 0 and finite part αx; the *finite part* of $\mathcal{S}(V)$ is the span $\mathcal{W}_f(V)$ of the vectors $\varrho_{f,V}(x)\mathrm{vac}_V$. For an adelic vector y its *finite coordinates* are $y_f = \alpha^{-1} \cdot (\text{finite part of } y)$. The *finite multiplier* of $g \in G_f(I)$ is a complex number $\Delta_f(g) \neq 0$; ψ_0 is the additive character $u \mapsto \psi_f(\mathbf{j}\alpha\bar{\alpha}u)$ of $\mathbb{A}_f$, ψ_f the standard one. For a set S of finite places, P^S is the bounded operator on $\mathcal{S}(V)$ that averages $\varrho_{f,V}(y)$ over the $y \in \hat{\mathcal{O}}^I$ supported at the places of S and their conjugates. For matrices $y \colon V \to V'$ in rational coordinates, $\varrho(y)$ denotes the Heisenberg operator of $\mathrm{Hom}(V, V')$ at the frame coordinates of y.

Input 1. (the Weil representation; background library, units of the folders *Weil/Construction* and *Adelic/Adeles*). Let V be a hermitian space with index set I over a field with Weil data. (a) $\varrho_{f,V}(x)\varrho_{f,V}(y) = \varsigma \cdot \varrho_{f,V}(x+y)$ with ς a value of ψ_0, and every value of ψ_0 is a root of unity; $\varrho_{f,V}(y)\mathrm{vac}_V = \mathrm{vac}_V$ for $y \in \hat{\mathcal{O}}^I$; $\varrho_{f,V}(x)$ maps $\mathcal{W}_f(V)$ into itself. (b) $\omega_V(g)\varrho_{f,V}(x) = \varrho_{f,V}(g_f x)\omega_V(g)$ and $\omega_V(g)(v \otimes f) = (\omega_V(g_\infty)v) \otimes \omega_V(1, g_f)f$, where $G_\infty(V)$ acts on $\mathcal{F}(V)$; for an adelic vector y and $v \in \mathcal{F}(V)$ there is $v_1 \in \mathcal{F}(V)$ with $\varrho_V(y)(v \otimes f) = v_1 \otimes \varrho_{f,V}(y_f)f$ for all f; $\varrho_{f,V}(x)(v \otimes f) = v \otimes \varrho_{f,V}(x)f$; and $\omega_V(1,g)$ maps $\mathcal{W}_f(V)$ into itself. (c) For $g \in G_f(I)$, $\omega_V(1,g)\mathrm{vac}_V = \Delta_f(g)|\Delta_f(g)|^{-2}\sum_y \varrho_{f,V}(gy)\mathrm{vac}_V$, the sum over representatives y of $\hat{\mathcal{O}}^I$ modulo $\hat{\mathcal{O}}^I \cap g^{-1}\hat{\mathcal{O}}^I$; the number of classes is $|\Delta_f(g)|^2$. (d) If $f \in \mathcal{W}_f(V)$ and $\varrho_{f,V}(gy)f = f$ for all $y \in \hat{\mathcal{O}}^I$, then $f = c \cdot \omega_V(1,g)\mathrm{vac}_V$ for some $c \in \mathbb{C}$. (e) A vector $u \in \mathbb{A}_f^I$ lies in $\hat{\mathcal{O}}^I$ if and only if $\psi_0(x^*u) = 1$ for every $x \in \hat{\mathcal{O}}^I$; and $\varrho_{f,V}(x)\varrho_{f,V}(y) = \psi_0(y^*x) \cdot \varrho_{f,V}(y)\varrho_{f,V}(x)$. (f) If $P^S f = f$, then $P^S(\varrho_{f,V}(y)f)$ is $\varrho_{f,V}(y)f$ if y is integral at the places of S and their conjugates, and 0 otherwise. *References.* The library gives as its sources for the Weil representation A. Weil, Acta Math. 111 (1964), and S. Kudla, Israel J. Math. 87 (1994); the catalogue of this write-up has not confirmed the places: reference to be confirmed. The formulas above are those of the lattice model.

Definition 2.3 (arrow products and the triple action; recalled)**.** Let E carry Weil data and let V, V', V'' be hermitian spaces with index sets I, I', I''. V^- is V with the matrix $-J_V$, the opposite signs and the frame x_V multiplied at the finite places by the idele $\overline{\epsilon}_\bar{\alpha}/\alpha$; an element g of $G(V)$, read in $G(V^-)$, is written g^-. For a character μ of $\mathrm{U}(1)(\mathbb{A})$ trivial on $\mathrm{U}(1)(E)$ put $\mu_V = \mu \cdot \upsilon^{\lfloor |I|/2 \rfloor}$. The *twisted pair action* on $\mathcal{S}(\mathrm{Hom}(V,V'))$ is $\omega_\mu^{\mathrm{pr}}(g,g') = \mu_V(\det g')\,\mu_{V'}(\det g)^{-1}\,\omega_{\mathrm{Hom}(V,V')}(g,g')$, and $\omega_\mu^{\mathrm{pr},f}$ is its restriction to finite points, acting on $\mathcal{W}_f(\mathrm{Hom}(V,V'))$. (The note on the Gauss-sum operator writes $\omega_{a,b}$ for the pair action twisted by two characters a, b; in that notation ω_μ^{pr} is the action with $a = \mu_V$ and $b = \mu_{V'}$.) The *arrow product* is a bounded bilinear map $(f,f') \mapsto f \boxtimes f'$ from $\mathcal{S}(\mathrm{Hom}(V,V')) \times \mathcal{S}(\mathrm{Hom}(V',V''))$ to $\mathcal{S}(\mathrm{Hom}(V', V^- \oplus V''))$; it induces the linear map $\mathrm{at}\colon \mathcal{W}_f(\mathrm{Hom}(V,V')) \otimes \mathcal{W}_f(\mathrm{Hom}(V',V'')) \to \mathcal{S}(\mathrm{Hom}(V', V^- \oplus V''))$, and $\mathrm{at}^\flat$ is a chosen linear left inverse of at. There is also a bounded bilinear arrow product of real data, $(v,v') \mapsto v \boxtimes v'$, from $\mathcal{F}(\mathrm{Hom}(V,V')) \times \mathcal{F}(\mathrm{Hom}(V',V''))$ to $\mathcal{F}(\mathrm{Hom}(V', V^- \oplus V''))$. The *triple action* of a triple (g,g',g'') of elements of $G(V)$, $G(V')$, $G(V'')$ on the space $\mathcal{S}(\mathrm{Hom}(V', V^- \oplus V''))$ is

$$\omega_{\mu,\mu'}^{\mathrm{tr}}(g,g',g'') = \mu_V(\det g')\,\mu_{V'}(\det g)^{-1}\,\mu'_{V'}(\det g'')\,\mu'_{V''}(\det g')^{-1} \cdot \upsilon(\det g)^{|I'|}\,\upsilon(\det g')^{-|I|} \cdot \omega(g', g^- \oplus g''),$$

ω the Weil representation of $\mathrm{Hom}(V', V^- \oplus V'')$.

Input 2. (two lifts as one pair; background library, unit of the folder *Weil/DualPair*). In the situation of Definition 2.3: (a) there is $z \neq 0$ with $\theta(f \boxtimes f') = z \cdot \theta(f)\theta(f')$ for all f, f'; (b) for matrices $y\colon V \to V'$, $y'\colon V' \to V''$ in rational coordinates, $\varrho\left(\begin{smallmatrix} y^\dagger \\ y' \end{smallmatrix}\right)(f \boxtimes f') = \varrho(y)f \boxtimes \varrho(y')f'$; (c) for a finite vector y of $\mathrm{Hom}(V', V^- \oplus V'')$, with blocks y_1 (indices $I \times I'$) and y_2 (indices $I'' \times I'$), $\varrho_f(y)(f \boxtimes f') = \varsigma \cdot \varrho_f(\epsilon_- y_1^*)f \boxtimes \varrho_f(y_2)f'$ with ς a root of unity, and $\mathrm{vac} \boxtimes \mathrm{vac} = \mathrm{vac}$; (d) $\omega_\mu^{\mathrm{pr}}(g, g')f \boxtimes \omega_{\mu'}^{\mathrm{pr}}(g', g'')f' = \omega_{\mu,\mu'}^{\mathrm{tr}}(g, g', g'')(f \boxtimes f')$, and for finite points $\mathrm{at} \circ (\omega_\mu^{\mathrm{pr},f}(p, q) \otimes \omega_{\mu'}^{\mathrm{pr},f}(q, r)) = \omega_{\mu,\mu'}^{\mathrm{tr}}((1, p), (1, q), (1, r)) \circ \mathrm{at}$; (e) at is injective, $\mathrm{at}^\flat \circ \mathrm{at} = 1$, and the range of at is $\mathcal{W}_f(\mathrm{Hom}(V', V^- \oplus V''))$; (f) $(g, g') \mapsto \theta(\omega_{\mu,\mu'}^{\mathrm{tr}}(g, g', k)f)$ is invariant under left multiplication by $\Gamma(V) \times \Gamma(V')$; (g) $\omega_\mu^{\mathrm{pr}}(g, g')\varrho(y) = \varrho(g'yg^{-1})\omega_\mu^{\mathrm{pr}}(g, g')$, with g, g' read in rational coordinates; (h) for real data v, v' and data f, f': $(v \otimes f) \boxtimes (v' \otimes f') = (v \boxtimes v') \otimes (f \boxtimes f')$; and for a polynomial Q_1 in the coordinates of $\mathrm{Hom}(V', V^-)$ and a polynomial Q_2 in those of $\mathrm{Hom}(V', V'')$, $v_{Q_1 Q_2} = v_{Q_1'} \boxtimes v_{Q_2}$, where Q_1' is the polynomial in the coordinates of $\mathrm{Hom}(V, V')$ obtained from Q_1 by sending each variable to the variable at the transposed position, with the sign that the formal text attaches to the two positions. *References:* none in the catalogue; reference to be confirmed. The catalogue classes the product formula for polynomial vectors in (h) as elementary.

Definition 2.4 (splittings and zero terms; recalled)**.** Let V, V_0 be hermitian spaces with index sets I, I_0 and H a finite index set. A *splitting* Ξ of V over V_0 along H consists of matrices $\mathsf{k}_\Xi, \mathsf{l}_\Xi \in M_{I \times H}(E)$ and $\mathsf{i}_\Xi \in M_{I \times I_0}(E)$ with $\mathsf{k}^* J_V \mathsf{k} = 0$, $\mathsf{l}^* J_V \mathsf{l} = 0$, $\mathsf{l}^* J_V \mathsf{k} = 1$, $\mathsf{i}^* J_V \mathsf{i} = J_{V_0}$, $\mathsf{i}^* J_V \mathsf{k} = 0$, $\mathsf{i}^* J_V \mathsf{l} = 0$ and $|I| = |I_0| + 2|H|$. In frame coordinates these are $x_V^{-1}\mathsf{k}_\Xi$, $x_V^{-1}\mathsf{l}_\Xi$ and $x_V^{-1}\mathsf{i}_\Xi x_{V_0}$; their finite parts are written $\mathsf{k}_{\Xi,f}$, $\mathsf{l}_{\Xi,f}$, $\mathsf{i}_{\Xi,f}$. If E carries Weil data, the *zero term* $\mathrm{ev}_\Xi\colon \mathcal{S}(V) \to \mathcal{S}(V_0)$ is the bounded linear map with $(\mathrm{ev}_\Xi f)(y)$ the mean of $f(x_V^{-1}\mathsf{i}_\Xi x_{V_0} y + x_V^{-1}\mathsf{k}_\Xi b)$ over $b \in \mathbb{A}^H$ modulo E^H. Splittings compose: one of V over V_0 and one of V_0 over V_1 give one of V over V_1, and the zero term of the composite is the composite of the zero terms. For a hermitian space V', a splitting Ξ of V over V_0 along H induces one of $\mathrm{Hom}(V', V)$ over $\mathrm{Hom}(V', V_0)$ along $H \times I'$. The space $\mathbb{H}^H \oplus V_0$ has the splitting over V_0 that *removes the planes*. An element $g \in G(V)$ is *adapted* to Ξ if the matrix with column blocks $g^{-1}x_V^{-1}(\mathsf{l}_\Xi, \mathsf{k}_\Xi, \mathsf{i}_\Xi x_{V_0})$ has orthonormal columns at every infinite place and integral entries at the finite places.

Input 3. (zero terms and the mixed model; background library, units of the folders *Weil/MixedModel* and *Weil/DualPair*). Let Ξ be a splitting of V over V_0 along H, over a field with Weil data. (a) An element of $G(V)$ adapted to Ξ exists. If g is adapted to Ξ, there are $c \neq 0$ and a function ϵ on $\mathbb{A}^H$ with $\mathrm{ev}_\Xi(\varrho_V(x_V^{-1}\mathsf{l}_\Xi b)\,\omega_V(g)\mathrm{vac}_V) = c\,\epsilon(b)\,\mathrm{vac}_{V_0}$ for all $b \in \mathbb{A}^H$, and there is a bounded linear map $\Lambda\colon \mathcal{F}(V) \to \mathcal{F}(V_0)$ with $\mathrm{ev}_\Xi(\omega_V(g)(v \otimes f)) = \Lambda v \otimes \mathrm{ev}_\Xi(\omega_V(g)(v_{\mathrm{vac}} \otimes f))$ for all v, f, where v_{vac} is the vacuum of $\mathcal{F}(V)$; moreover $v_{\mathrm{vac}} \otimes f = f$ for $f \in \mathcal{W}_f(V)$. (b) $\mathrm{ev}_\Xi(\varrho_V(x_V^{-1}\mathsf{i}_\Xi x_{V_0} y)f) = \varrho_{V_0}(y)\,\mathrm{ev}_\Xi(f)$ and $\mathrm{ev}_\Xi(\varrho_V(x_V^{-1}\mathsf{k}_\Xi b)f) = \mathrm{ev}_\Xi(f)$. (c) Every $y \in \mathbb{A}_f^I$ is $\mathsf{l}_{\Xi,f}a + \mathsf{i}_{\Xi,f}w + \mathsf{k}_{\Xi,f}b$ for unique a, w, b, and $a = \mathsf{k}^*_{\Xi,f}y$, $w = \mathsf{i}^*_{\Xi,f}y$. (d) Suppose that k_Ξ is the inclusion of the basis vectors of positive weight, for weights $\mathrm{wt}\colon I \to \mathbb{Z}$. Let $g \in G(V)$, $g_0 \in G(V_0)$, let C be an $I \times I$ matrix over $\mathbb{A}$ and u an idele of norm one, and suppose, in rational coordinates: g and C have the same columns of positive weight; the entry (b,a) of $C-1$ vanishes whenever $\mathrm{wt}(b) \leq \min(0, \mathrm{wt}(a))$; $\det C = u$; and $g\,\mathsf{i}_\Xi - \mathsf{i}_\Xi g_0$ has non-zero entries only in rows of positive weight. Then $\mathrm{ev}_\Xi(\omega_V(g)f) = v(u)^{-1}\omega_{V_0}(g_0)\,\mathrm{ev}_\Xi(f)$ for all f. (e) For the splitting of $\mathrm{Hom}(V', \mathbb{H}^H \oplus V_0)$ over $\mathrm{Hom}(V', V_0)$ induced by removing the planes, and $h \in G(V')$, $r \in G(V_0)$: $\mathrm{ev}(\omega(h, 1 \oplus r)f) = v(\det h)^{|H|}\omega(h,r)\,\mathrm{ev}(f)$. (f) For a set S of finite places disjoint from its conjugate, functions Ψ of the components at S of a finite vector *name* operators $\Psi \otimes$ on $\mathcal{S}(V)$: the indicator of the vectors integral at S names P^S; the name of its translate by y is $\varrho_{f,V}(y_S) \circ P^S$ up to a root of unity, y_S the part of y at S and its conjugate; and for $g \in G_f(I)$ with component 1 outside S and its conjugate, $\omega_V(1,g) \circ (\Psi \otimes) = C_g \cdot (\Psi(g^{-1}\,\cdot) \otimes)$ with a constant $C_g \in \mathbb{C}$. *References.* The library gives as its sources Mœglin–Vignéras–Waldspurger, LNM 1291 (1987), and S. Kudla, Israel J. Math. 87 (1994); not confirmed by the catalogue: reference to be confirmed.

Definition 2.5 (gradings, Bessel groups, constant terms; recalled)**.** A *grading* $\mathcal{Y}$ of a hermitian space V (index set I) with *definite part* X and a string of length l, of *norm* $N \in E^\times$, $\bar{N} = N$, consists of a bijection $\mathbf{e}_y\colon X \sqcup \{0, \dots, l-1\} \to I$ with $J_V = \mathrm{Gr}_{\mathbf{e}_y}(N)$ and a constant $\mathfrak{c}(\mathcal{Y}) \in E^\times$, $\overline{\mathfrak{c}(\mathcal{Y})} = \mathfrak{c}(\mathcal{Y})$. Here $\mathrm{Gr}_{\mathbf{e}}(N)$ is the matrix that is the identity on X, pairs the string vectors a and $l-1-a$ to 1 for $a \neq l-1-a$, and has the entry $-N$ at the middle string vector $a = l-1-a$ (which exists when l is odd). The *grade* gr_y is 0 on X and $l-1-2a$ at the string vector a. The homomorphism $\imath_y\colon G(\langle X \rangle) \to G(V)$ lets a unitary matrix act on X and fixes the string vectors (in rational coordinates), and $\imath_y^f$ is its restriction to finite points. The *Bessel group* $B(\mathcal{Y})$ is the group of the $g \in G(V)$ that, in rational coordinates, fix every string vector of grade ≥ 0 up to string vectors of higher grade; it contains $\imath_y(G(\langle X \rangle))$ and the group of the *unipotent* elements, those g for which $g-1$ strictly raises grades. $[B(\mathcal{Y})]$ is the quotient of $B(\mathcal{Y})$ by its rational points, with the measure of the library. If E carries Weil data, a function $P\colon G(V) \to \mathbb{C}$ is *generic* for $\mathcal{Y}$ if it is continuous, left invariant

under the rational points of $B(\mathcal{Y})$, and multiplied by an explicit character under left multiplication by the unipotent elements n for which $n-1$ raises grades by at least 2. For a second grading $\mathcal{Y}'$ of V' with definite part X', the *string map* $T_{\mathcal{Y},\mathcal{Y}'}\colon V \to V'$ (the library's name; it carries the frequencies of the constant terms below) is the rational matrix that kills X and sends the string vector a of $\mathcal{Y}$ to a multiple of the string vector a of $\mathcal{Y}'$, the multiple being one of 1, $\mathfrak{c}(\mathcal{Y})$, $-N\mathfrak{c}(\mathcal{Y})$ according to the grade: for odd l it is 1, $-N\mathfrak{c}(\mathcal{Y})$, $\mathfrak{c}(\mathcal{Y})$ at positive, zero, negative grade, for even l it is $\mathfrak{c}(\mathcal{Y})$, 1 at positive, negative grade. The *shift* $\mathrm{sh}_{\mathcal{Y}}$ is the rational matrix $V \to V$ that kills X and sends the string vector a to a multiple of the string vector $a+1$ (the last one to 0), the multiple being $\mathfrak{c}(\mathcal{Y})$ times $-N$ if a is the middle string vector, times $-N\mathfrak{c}(\mathcal{Y})$ if l is even and a has grade 1, and times 1 otherwise. The *degree* of the position $(b,a) \in I' \times I$ is $\mathrm{gr}_{\mathcal{Y}'}(b) - \mathrm{gr}_{\mathcal{Y}}(a)$. The *constant term at the string map* of a datum $f \in \mathcal{S}(\mathrm{Hom}(V,V'))$, for a character μ as in Definition 2.3, is the function $\mathrm{ct}^{\mu}_{\mathcal{Y},\mathcal{Y}'}(f)$ on $G(V)\times G(V')$ whose value at (g,r) is the mean of

$$\theta\big(\varrho(n)\,\varrho(T_{\mathcal{Y},\mathcal{Y}'})\,\omega^{\mathrm{pr}}_{\mu}(g,r)f\big)$$

over the adelic matrices $n\colon V \to V'$ with entries only in positions of positive degree, modulo the rational ones. Finally, the *Heisenberg bicharacter* of $\mathrm{Hom}(V,V')$ is $\mathrm{bi}(x,y) = \psi_{\mathbb{A}}\big(\frac{1}{2}\mathbf{j}\,\mathrm{tr}(y^{\dagger}x)\big)$ for adelic matrices $x, y\colon V \to V'$, where $\psi_{\mathbb{A}}$ is the standard additive character of $\mathbb{A}$ trivial on E; the product $\varrho(x)\varrho(y)$ is $\varrho(x+y)$ times a value of it.

Input 4. (Bessel periods; background library, unit of the folder *Weil/Periods*). Let $\mathcal{Y}$, $\mathcal{Y}'$ be gradings of V, V' over a field with Weil data. (a) Let H be a finite index set and $\gamma\colon H \hookrightarrow \{b \in I : \mathrm{gr}_{\mathcal{Y}}(b) = 1\}$ an injection. There is $C \in \mathbb{C}$ such that $\int_{[B(\mathcal{Y})]} \phi = C \int_{[G(\langle X\rangle)]} M$ whenever ϕ is a continuous function on $G(V)$, left invariant under the rational points of $B(\mathcal{Y})$, such that for every $a \in G(\langle X\rangle)$ the function $n \mapsto \phi(n\,\imath_{\mathcal{Y}}(a))$ of unipotent n is a continuous function, periodic for the rational matrices, of mean $M(a)$, of the entries of $\mathfrak{c}(\mathcal{Y})(n-1)$ in the rows $\gamma(H)$ and the columns X (in rational coordinates), and M is continuous and left invariant under $\Gamma(\langle X\rangle)$. (b) If P is generic for $\mathcal{Y}$ and n is unipotent with $n-1$ raising grades by at least 2, then $g \mapsto P(ng)\cdot$(constant term of $\omega^{\mathrm{pr}}_{\mu}(ng,r)f$ at a matrix y) equals $\mathrm{bi}(T_{\mathcal{Y},\mathcal{Y}'}n, T_{\mathcal{Y},\mathcal{Y}'})/\,\mathrm{bi}(yn,y)$ times the same expression at g, provided $y(n-1)$ has only entries in positions of positive degree; here $l' = l-1$. (c) $\mathrm{ct}^{\mu}_{\mathcal{Y},\mathcal{Y}'}(f)(\gamma g,\gamma' r) = \mathrm{ct}^{\mu}_{\mathcal{Y},\mathcal{Y}'}(f)(g,r)$ for rational points γ, γ' of the two Bessel groups; and the constant term of $\omega^{\mathrm{pr}}_{\mu}(ng,n'r)f$ at a matrix y is that of $\omega^{\mathrm{pr}}_{\mu}(g,r)f$ at $n'^{-1}yn$, for unipotent n and n' with $n'-1$ raising degrees. (d) If $l' = l-1$, then $T^{\dagger}_{\mathcal{Y},\mathcal{Y}'}\,T_{\mathcal{Y},\mathcal{Y}'} = \mathrm{sh}_{\mathcal{Y}}$; and if moreover $\mathfrak{c}(\mathcal{Y}') = \mathfrak{c}(\mathcal{Y})$, then $T_{\mathcal{Y},\mathcal{Y}'}\,T^{\dagger}_{\mathcal{Y},\mathcal{Y}'} = \mathrm{sh}_{\mathcal{Y}'}$. *References.* The library gives as its source for the unfolding of Bessel periods B. Wang Peng Jun, J. Number Theory 271 (2025), Prop. 3.2 and Thm. 4.5, and the authors record the place as compared; the catalogue of this write-up has not confirmed it: reference to be confirmed.

Input 5. (algebraic forms and theta lifts; background library, units of the folders *Adelic/CuspForms* and *Weil/Periods*). For a finite index set X, a weight $\varkappa$ and a determinant exponent e, $\mathcal{A}(X;\varkappa,e)$ is the space of algebraic modular forms of weight $(\varkappa,e)$ on the definite unitary group of $\langle X\rangle$: functions on $G_f(X)$ with values in the space of vectors of weight $\varkappa$ for X (the catalogue names B. Gross, Algebraic modular forms, Israel J. Math. 113 (1999), for this notion; place not confirmed). For a linear functional t on that space of vectors, $\mathrm{coef}_t(\varphi)$ is the function $g \mapsto t(\bar{g}_\infty^{-1}\varphi(g_f))$ on $G(\langle X\rangle)$; it is continuous and left invariant under $\Gamma(\langle X\rangle)$. Let E carry Weil data. A family of linear maps $\mathcal{L}_o\colon \mathcal{W}_f(\mathrm{Hom}(\langle X\rangle,\langle X'\rangle)) \to \mathrm{Hom}_{\mathbb{C}}(\mathcal{A}(X;\varkappa,e),\mathcal{A}(X';\varkappa,e'))$, $o\in U$, is a *family of theta lifts* for characters $(\mu_o)_{o\in U}$ if for every complex polynomial Q and every functional t there is a functional t' such that for all $o\in U$, Φ, φ and $h\in G(\langle X'\rangle)$

$$\int_{[G(\langle X\rangle)]} \theta\big(\omega^{\mathrm{pr}}_{\mu_o}(g,h)(v_Q\otimes\Phi)\big)\,\mathrm{coef}_t(\varphi)(g)\,dg = \mathrm{coef}_{t'}\big(\mathcal{L}_o(\Phi)\varphi\big)(h).$$

This is a definition of the library; the lifts to which the seesaw note applies it are theta lifts in this sense by a result of the library that this note does not use.

LEAN `Space.isAutomorphic_algFormCoeff`

Input 6. (Hermite reduction; background library, unit of the folder *Adelic/Witt*). Let I, H be finite index sets and Y an $I\times H$ matrix over $\mathbb{A}_f$ that has a left inverse. Then there is an invertible $H\times H$ matrix t over $\mathbb{A}_f$ such that Yt has entries in $\hat{\mathcal{O}}$ and a left inverse with entries in $\hat{\mathcal{O}}$. (The library proves this for pairs of a ring and a subring with a valuation property, with t block triangular; the catalogue classes it as elementary.)

LEAN `IsValuationPair.exists_isPrimitiveMatrix_mul`

Input 7. (analysis; background library). (a) The polynomial vectors v_Q are dense in the space $\mathcal{F}(V)$ of real data (folder *Weil/Fock*). (b) If two families of variables together exhaust the variables of a polynomial ring over $\mathbb{C}$, every polynomial is a finite sum of products of a polynomial in the first family with a polynomial in the second (folder *General/LinearAlgebra*). (c) Let $\phi\colon \mathsf{A}\times\mathsf{A}'\to\mathsf{B}$ be a continuous surjective homomorphism of topological abelian groups that maps the product of two cocompact lattices into a cocompact lattice of B. Then the mean over A of the mean over A' of $F\circ\phi$ is the mean of F over B, each mean taken modulo its lattice (folder *Adelic/QuotientMeasure*). (d) If a prime ℓ does not divide the natural number n, then $|n|=1$ in every normed field that is a normed algebra over the ℓ-adic numbers (folder *General/Algebra*).

Setting 2.6 (three graded spaces)**.** E is a CM field with a CM type and Weil data. V, V', V'' are hermitian spaces over E with finite index sets I, I', I'' and their signs. y, y', y'' are gradings of V, V', V'' of the same norm $N\in E$, with finite definite parts X, X', X_0 and strings of lengths l, l', l''.

Admissible combinations.

Definition 2.7 (integral away from n)**.** For a natural number n, $O^{(n)}$ is the set of the complex numbers w with $|\jmath(w)|_\ell \le 1$ for every prime number ℓ coprime to n and every ring homomorphism $\jmath\colon \mathbb{C} \to \mathbb{C}_\ell$. It is a subring of $\mathbb{C}$, by the ultrametric inequality, and $O^{(n)} \subseteq O_\jmath$ for every such ℓ and $\jmath$.

LEAN `integralAway`

Definition 2.8 (admissible coefficients and combinations)**.** Let $\mathcal{X}$ be a set, $A \subseteq \mathcal{X}$, n and d natural numbers, p a proposition and B a real number. A finitely supported function $r\colon \mathcal{X} \to \mathbb{C}$ is *admissible*, written $r \in \mathrm{Co}(A; n, d; p, B)$, if its support lies in A; $d \cdot r(x) \in O^{(n)}$ for every $x \in \mathcal{X}$; and, if p holds, $\sum_x |\sigma(r(x))| \le B$ for every field automorphism σ of $\mathbb{C}$. For a complex vector space Z, a family $v\colon \mathcal{X} \to Z$ and $z \in Z$ we write $z \in \mathrm{Adm}(v, A; n, d; p, B)$ if $z = \sum_x r(x)v(x)$ for some r with $r \in \mathrm{Co}(A; n, d; p, B)$: z is an *admissible combination* of the $v(x)$, $x \in A$, *away from* n, with *denominator* d and, under p, *size* B. The size is an upper bound, and it is asked only when p holds.

LEAN `IsAdmissibleCoeffs` · `IsAdmissibleComb`

Translations and lattices.

Definition 2.9 (groups of translations)**.** Let E be a CM field, I an index set, n a natural number and $d\colon I \to \mathbb{A}_f$ a family of finite adeles. $\mathrm{Tr}_n[d]$ is the additive group of the $x \in \mathbb{A}_f^I$ such that $d_i x_i$ is integral at every finite place that does not divide n, for every $i \in I$. For a single finite adele d, $\mathrm{Tr}_n^I[d]$ is the group $\mathrm{Tr}_n[d]$ for the constant family $i \mapsto d$ on I. For index sets I_1, I_2, $\beta \in \hat{\mathcal{O}}$ and $j \in I_1 \sqcup I_2$ we put $\beta^{\langle j \rangle} = \beta$ if $j \in I_1$ and $\beta^{\langle j \rangle} = \bar{\beta}$ if $j \in I_2$.

LEAN `weightedTranslations` · `translations` · `selfOrConj`

Definition 2.10 (split and squarefree)**.** Let E be a CM field with a CM type, Σ a finite set of finite places of E, $N \in E$ and π a finite idele. We write $\mathsf{SqF}_\Sigma(N; \pi)$, and say that N is *split and squarefree along* Σ through π, if $N = \pi\bar{\pi}$ in $\mathbb{A}_f$ and, for every finite place w, $|\pi_w|_w = e^{-1}$ if $w \in \Sigma$ and $|\pi_w|_w = 1$ otherwise, and $w \in \Sigma$ implies $\bar{w} \notin \Sigma$.

LEAN `IsSplitSquarefree`

Definition 2.11 (graded lattice basis)**.** Let R be a commutative ring with an involution, X and I index sets, l a natural number, $\mathbf{e}\colon X^+ \sqcup \{0, \dots, l-1\} \to I$ a bijection, a and π units of R and $u \in R$ with $u\bar{u} = 1$. The matrix $\mathsf{L}_\mathbf{e}(a, \pi, u) \in M_I(R)$ is defined by its columns, indexed through $\mathbf{e}$ (write e_i for the basis vectors). If l is odd, with middle string index z: the column of $x \in X$ is e_x, the column of pt is $\bar{\pi}^{-1}e_{\mathrm{pt}} + u(\pi\bar{\pi})^{-1}e_z$, and the column of a string index b is ue_b. If l is even: the column of $x \in X^+$ is e_x, and the column of a string index b is $ua^{-1}e_b$ if $2b < l$ and $u\bar{a}e_b$ otherwise.

Let now E be a CM field with a CM type, V a hermitian space with index set I, and $\mathcal{Y}$ a grading of V with definite part X^+ and a string of length l, of norm N; let a, π be finite ideles and u a finite adele with $u\bar{u} = 1$. We write $\mathsf{Lat}(\mathcal{Y}; a, \pi, u)$ if

$x_{V,f} = \mathsf{L}_{\mathbf{e}_y}(a, \pi, u) \cdot k$ for some $k \in \mathrm{GL}_I(\hat{\mathcal{O}})$: the columns of the finite frame of V and of the graded lattice basis span the same lattice.

LEAN gradedLatticeBasis · Grading.SpansLattice

Zero terms and arrow pairs.

Definition 2.12 (the finite zero term)**.** Let E carry Weil data and let Ξ be a splitting of V over V_0 along H (Definition 2.4; index sets I, I_0; signs as in Definition 2.1). Choose an element of $G(V)$ adapted to Ξ (Input 3(a)), let g_∞ be its real component and $v_\Xi = \omega_V(g_\infty)v_{\mathrm{vac}} \in \mathcal{F}(V)$. The *finite zero term* is the bounded linear map

$$\mathrm{ev}^f_\Xi \colon \mathcal{S}(V) \to \mathcal{S}(V_0), \qquad \mathrm{ev}^f_\Xi(f) = \mathrm{ev}_\Xi(v_\Xi \otimes f).$$

LEAN zeroTermFin

Definition 2.13 (grade-zero parts)**.** Let E carry Weil data, let V, V'' be hermitian spaces with index sets I, I'' and their signs, and $\mathrm{wt} \colon I \to \mathbb{Z}$ a function (*weights*). A *grade-zero part* of V for wt with zero part V'', an element of the set $\mathrm{GZ}(V, V''; \mathrm{wt})$, is a pair $\mathcal{Z} = (\mathrm{ind}_\mathcal{Z}, \mathrm{inc}_\mathcal{Z})$ of an injection $\mathrm{ind}_\mathcal{Z} \colon I'' \hookrightarrow I$ whose image is $\{i : \mathrm{wt}(i) = 0\}$ and a matrix $\mathrm{inc}_\mathcal{Z} \in M_{I \times I''}(E)$ such that $\mathrm{inc}_\mathcal{Z}(a, b) = 0$ whenever $\mathrm{wt}(a) \neq 0$, such that $\mathrm{inc}^*_\mathcal{Z} J_V \mathrm{inc}_\mathcal{Z} = J_{V''}$, and such that $J_V(a, b) \neq 0$ implies $\mathrm{wt}(a) + \mathrm{wt}(b) = 0$. Its *splitting* $\Xi(\mathcal{Z})$ is the splitting of V over V'' along $\{i : \mathrm{wt}(i) > 0\}$ with k the inclusion of the basis vectors of positive weight, $\mathsf{l} = J_V^{-1}\mathsf{k}$ and $\mathsf{i} = \mathrm{inc}_\mathcal{Z}$; the equations of Definition 2.4 hold because J_V and J_V^{-1} pair only opposite weights.

LEAN GradeZeroPart · GradeZeroPart.splitting

Definition 2.14 (the grade-zero part of a space of homomorphisms)**.** Let E carry Weil data, let V, V', V'' be hermitian spaces with index sets I, I', I'', let $\mathcal{Y}'$ be a grading of V' of norm N with definite part X' and a string of length l', let $\mathrm{wt} \colon I \to \mathbb{Z}$ and $\mathcal{Z} \in \mathrm{GZ}(V, V''; \mathrm{wt})$. Suppose that l' is even and that $\mathrm{wt}(i)$ is even for every $i \in I$. Then $\mathrm{Hom}(\mathcal{Y}', \mathcal{Z})^0$ is the grade-zero part of $\mathrm{Hom}(V', V)$ for the weights $(i, j) \mapsto \mathrm{wt}(i) - \mathrm{gr}_{\mathcal{Y}'}(j)$, with zero part $\mathrm{Hom}(\langle X' \rangle, V'')$: its injection is $\mathrm{ind}_\mathcal{Z}$ times the inclusion of X' into I' along $\mathbf{e}_{\mathcal{Y}'}$, and its matrix is the Kronecker product of $\mathrm{inc}_\mathcal{Z}$ with the inclusion matrix of X'. (The two hypotheses make $\mathrm{wt}(i) - \mathrm{gr}_{\mathcal{Y}'}(j) = 0$ possible only for $j \in X'$.)

LEAN GradeZeroPart.hom

Definition 2.15 (the stacked string map)**.** In Setting 2.6, $\mathbf{T}(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}'')$ is the adelic matrix $V' \to V^- \oplus V''$ in rational coordinates with the two row blocks $T^\dagger_{\mathcal{Y},\mathcal{Y}'}$ (rows I) and $T_{\mathcal{Y}',\mathcal{Y}''}$ (rows I''), and $\mathbf{T}_f(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}'')$ is the vector of the finite coordinates of its frame coordinates, a finite vector of $\mathrm{Hom}(V', V^- \oplus V'')$.

LEAN stackedT · stackedTFin

Definition 2.16 (arrow pairs)**.** In Setting 2.6, let X'' and H be finite index sets. An *arrow pair* for $\mathcal{Y} \to \mathcal{Y}' \to \mathcal{Y}''$, an element of the set $\mathrm{Arr}_{X'',H}(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}'')$, consists of the following.

(a) A grade-zero part $\mathcal{Z}_\mathcal{R} \in \mathrm{GZ}(V^- \oplus V'', \mathbb{H}^H \oplus (\langle X \rangle^- \oplus \langle X'' \rangle); \mathrm{gr}_\mathcal{Y} \sqcup \mathrm{gr}_{\mathcal{Y}''})$; its matrix is written $\mathrm{inc}_\mathcal{R}$ and its injection $\mathrm{ind}_\mathcal{R}$.

(b) The conditions: l is odd, $l' = l - 1$, $l'' = l' - 1$ (subtraction of natural numbers, truncated at 0: so $l'' = l - 2$ if $l \geq 3$ and $l' = l'' = 0$ if $l = 1$), $\mathfrak{c}(y') = \mathfrak{c}(y)$, and $|I| + |I''|$ is even.

(c) A homomorphism $\mathrm{emb}_{\mathcal{R}} \colon G(\langle X_0 \rangle) \to G(\langle X'' \rangle)$ with $\det \mathrm{emb}_{\mathcal{R}}(k) = \det k$, such that for all $g \in G(\langle X \rangle)$ and $k \in G(\langle X_0 \rangle)$, in rational coordinates,

$$(\imath_y(g) \oplus \imath_{y''}(k)) \cdot \mathrm{inc}_{\mathcal{R}} = \mathrm{inc}_{\mathcal{R}} \cdot (1 \oplus g^- \oplus \mathrm{emb}_{\mathcal{R}}(k)).$$

(d) An injection $\gamma_{\mathcal{R}} \colon H \hookrightarrow \{b \in I' : \mathrm{gr}_{y'}(b) = 1\}$ such that for every index a of the zero part and every $b \in I'$ the entry of $\mathbf{T}(y, y', y'')$ at $(\mathrm{ind}_{\mathcal{R}}(a), b)$ is $\sum_{k \in H,\ \gamma_{\mathcal{R}}(k) = b} \mathrm{inc}_{\mathcal{R}}(\mathrm{ind}_{\mathcal{R}}(a), k^*) \cdot \mathfrak{c}(y')$, where k^* is the index of the k-th vector of the second copy of H in $\mathbb{H}^H$.

LEAN `ArrowPair`

Definition 2.17 (the splitting and the finite evaluation of an arrow pair)**.** In Setting 2.6, let X'', H be finite index sets and $\mathcal{R} \in \mathrm{Arr}_{X'',H}(y, y', y'')$. (i) $\mathcal{Z}^{\mathrm{Hom}}(\mathcal{R}) = \mathrm{Hom}(y', \mathcal{Z}_{\mathcal{R}})^0$ is the grade-zero part of $\mathrm{Hom}(V', V^- \oplus V'')$ with zero part $\mathrm{Hom}(\langle X' \rangle, \mathbb{H}^H \oplus (\langle X \rangle^- \oplus \langle X'' \rangle))$; Definition 2.14 applies because l' is even and the grades of y and y'' are even, l being odd and l'' odd or zero. (ii) $\Xi^{\mathrm{pr}}(\mathcal{R})$ is the splitting of $\mathrm{Hom}(V', V^- \oplus V'')$ over $\mathrm{Hom}(\langle X' \rangle, \langle X \rangle^- \oplus \langle X'' \rangle)$ obtained by composing the splitting $\Xi(\mathcal{Z}^{\mathrm{Hom}}(\mathcal{R}))$ with the splitting induced by removing the H planes. (iii) The *finite evaluation* of $\mathcal{R}$ is the linear map

$$\mathrm{fev}_{\mathcal{R}} = \mathrm{at}^\flat \circ \mathrm{ev}^f_{\Xi^{\mathrm{pr}}(\mathcal{R})} \circ \varrho_f(\mathbf{T}_f(y, y', y''))$$

from $\mathcal{S}(\mathrm{Hom}(V', V^- \oplus V''))$ to $\mathcal{W}_f(\mathrm{Hom}(\langle X \rangle, \langle X' \rangle)) \otimes \mathcal{W}_f(\mathrm{Hom}(\langle X' \rangle, \langle X'' \rangle))$.

LEAN `ArrowPair.homZeroPart` · `ArrowPair.splitting` · `ArrowPair.finEval`

Definition 2.18 (the middle pair and the last pair)**.** In Setting 2.6, suppose that l is odd, $l' = l - 1$, $l'' = l' - 1$ and $\mathfrak{c}(y') = \mathfrak{c}(y)$, and that $|I| + |I''|$ is even. Let z, z'' be the middle string vectors of y and y''.

(i) If $l \neq 1$, the *middle pair* $\mathcal{R}_{\mathrm{mid}}(y, y', y'')$, an element of $\mathrm{Arr}_{X_0, \{\mathrm{pt}\}}(y, y', y'')$, removes one hyperbolic plane: its zero part sends the two basis vectors of the plane to $(2N)^{-1}(z - z'')$ and $z + z''$, and the basis vectors of X and of X_0 to the corresponding basis vectors of V and V''; its homomorphism emb is the identity of $G(\langle X_0 \rangle)$; its injection γ picks the string vector of y' with index $(l'' - 1)/2$, which has grade 1.

(ii) If $l = 1$, and $\pi_0 \in E$ satisfies $\pi_0 \overline{\pi_0} = N$, the *last pair* $\mathcal{R}_{\mathrm{last}}(y, y', y''; \pi_0)$, an element of $\mathrm{Arr}_{X_0^+, \emptyset}(y, y', y'')$, removes no plane: its zero part sends the basis vectors of X and of X_0 to the corresponding basis vectors and the new point to z/π_0, z the only string vector of y; its homomorphism emb is the block embedding $k \mapsto k \oplus 1$ of $G(\langle X_0 \rangle)$ into $G(\langle X_0^+ \rangle)$.

In both cases the conditions of Definition 2.16 are verified entry by entry from the explicit matrices $\mathrm{Gr}_{\mathbf{e}}(N)$ and the definition of the string maps.

Admissible evaluations.

Setting 2.19 (data at a split prime)**.** E is a CM field with a CM type and Weil data, and X, X'' are finite index sets. N is a prime number and Σ a finite set of finite places of E that is a *split level* for N in the sense of the note on the Gauss-sum operator: $\bar{w} \notin \Sigma$ for $w \in \Sigma$, every $w \in \Sigma$ has norm N and N is a uniformiser at w, and a finite place divides N exactly if it or its conjugate lies in Σ. π is a finite idele with $\mathsf{SqF}_{\Sigma}(N;\pi)$. δ is a finite adele with $\delta\bar{\delta} = 1$, and $\beta \in \hat{\mathcal{O}}$, such that $\delta_w = 1$ and $|\beta_w|_w = 1$ at every finite place w dividing N. Finally $\kappa\colon X^+ \sqcup X''^+ \to \mathbb{A}_f$ is a family with $\kappa_b \in \{1, \delta\}$, $\bar{\beta}\kappa_b \in \hat{\mathcal{O}}$ and $\beta^{\langle b\rangle}\kappa_b \in \hat{\mathcal{O}}$ for every b.

Definition 2.20 (neighbour vectors)**.** Let E carry Weil data, let X, H be finite index sets, π a finite idele, δ and c finite adeles and x a vector over $\mathbb{A}_f$ indexed by $X^+ \sqcup H^+$; write pt_1, pt_2 for the points of X^+ and H^+. We write $\mathsf{Nb}_{\pi,\delta}(c;x)$, and call (c,x) a *neighbour vector* for (π,δ), if: $\delta c = c$; $x_i \in \hat{\mathcal{O}}$ for every index i other than pt_1, pt_2; $\bar{\pi}x_i \in \hat{\mathcal{O}}$ for every i; $c - \pi^{-1}x_{\mathrm{pt}_1} \in \hat{\mathcal{O}}$; and $\overline{\epsilon_}c - \pi^{-1}x_{\mathrm{pt}_2} \in \hat{\mathcal{O}}$.

LEAN `IsNeighbourVector`

Definition 2.21 (admissible evaluations)**.** Let E carry Weil data; let V, V', V'' be hermitian spaces with index sets I, I', I'' and their signs, and X, X', X'' finite index sets. Let N be a prime number, Σ a finite set of finite places, $\beta \in \hat{\mathcal{O}}$, $d\colon I \sqcup I'' \to \mathbb{A}_f$ a family (by default $d = \beta^{\langle\cdot\rangle}$), and L a map from $\mathcal{S}(\mathrm{Hom}(V', V^- \oplus V''))$ to $\mathcal{W}_f(\mathrm{Hom}(\langle X^+\rangle, \langle X'\rangle)) \otimes \mathcal{W}_f(\mathrm{Hom}(\langle X'\rangle, \langle X''^+\rangle))$. We write $\mathsf{AdmEv}_{N,\Sigma,\beta}(L;d)$, and call L an *admissible evaluation* for (N,Σ,β) with weights d, if there is $C \in \mathbb{C}$ such that for every natural number n coprime to N, every proposition p and every $y \in \mathrm{Tr}_n[(i,i') \mapsto d_i]$ (a finite vector indexed by $(I \sqcup I'') \times I'$)

$$L\big(\varrho_f(y)\mathrm{vac}\big) \in \mathrm{Adm}(v_C, A_n; n, D; p, 1),$$

where v_C is the family $t = (t_1, t_2) \mapsto C \cdot \mathsf{T}_{N,\Sigma}(X, X', X'')(\varrho_f(t_1)\mathrm{vac} \otimes \varrho_f(t_2)\mathrm{vac})$, the set A_n is the product of $\mathrm{Tr}_n^{X'\times X^+}[\bar{\beta}]$ and $\mathrm{Tr}_n^{X''^+\times X'}[\bar{\beta}]$, D is the number of maps from $(X^+ \sqcup X''^+) \times X'$ to $\hat{\mathcal{O}}/\beta\hat{\mathcal{O}}$ (zero if infinite), and $\mathsf{T}_{N,\Sigma}(X, X', X'')$ is the translate sum of the note on the Gauss-sum operator: the operator $\sum_y \varrho_f(\mathrm{c}(y)) \otimes \varrho_f(\mathrm{r}(y))$ on $\mathcal{W}_f(\mathrm{Hom}(\langle X^+\rangle, \langle X'\rangle)) \otimes \mathcal{W}_f(\mathrm{Hom}(\langle X'\rangle, \langle X''^+\rangle))$, the sum over $y \in ((\mathbb{Z}/N)^{\Sigma})^{X'}$, where the matrix $\mathrm{c}(y)$ has last column $-\tilde{y}/N$ and $\mathrm{r}(y)$ has last row $-\overline{\tilde{y}/N}$, both zero elsewhere, and $\tilde{y}/N$ is the finite adele with component $\tilde{y}_w/N$ at $w \in \Sigma$, $\tilde{y}_w$ the least non-negative representative, and 0 at the other places.

LEAN `IsAdmissibleEval`

3 Admissible combinations

Lemma 3.1 (rules)**.** *Let $\mathcal{X}$, $\mathcal{X}'$ be sets, Z, Z', W complex vector spaces, $v\colon \mathcal{X} \to Z$ a family, $A \subseteq \mathcal{X}$, $A' \subseteq \mathcal{X}'$, n, d, d' natural numbers, p a proposition and B, B' real numbers.*

(a) Let $F \subseteq \mathcal{X}$ be a finite subset and $c\colon \mathcal{X} \to \mathbb{C}$ a function such that $d \cdot c(x) \in O^{(n)}$ for every $x \in F$, and such that p implies $\sum_{x\in F}|\sigma(c(x))| \le B$ for every automorphism σ. Then $\sum_{x\in F} c(x)v(x) \in \mathrm{Adm}(v, F; n, d; p, B)$.

(b) If $x \in A$, then $v(x) \in \mathrm{Adm}(v, A; n, d; p, 1)$.

In (c) to (g) let $z \in Z$ with $z \in \mathrm{Adm}(v, A; n, d; p, B)$.

(c) For a linear map $L\colon Z \to Z'$, $L(z) \in \mathrm{Adm}(L \circ v, A; n, d; p, B)$.

(d) If $c \in O^{(n)}$, and p implies $|\sigma(c)| \le 1$ for every automorphism σ, then $c \cdot z \in \mathrm{Adm}(v, A; n, d; p, B)$.

(e) If $\varsigma \in \mathbb{C}$ is zero or a root of unity, then $\varsigma \cdot z \in \mathrm{Adm}(v, A; n, d; p, B)$.

(f) Let $v'\colon \mathcal{X}' \to Z$. If for every $x \in A$ there are a root of unity ς and $y \in A'$ with $v(x) = \varsigma \cdot v'(y)$, then $z \in \mathrm{Adm}(v', A'; n, d; p, B)$.

(g) Let $v'\colon \mathcal{X}' \to Z'$ be a family, let $z' \in Z'$ satisfy $z' \in \mathrm{Adm}(v', A'; n, d'; p, B')$, and let $b\colon Z \times Z' \to W$ be bilinear. Then, for the family $v_b\colon (x, x') \mapsto b(v(x), v'(x'))$ on $\mathcal{X} \times \mathcal{X}'$, $b(z, z') \in \mathrm{Adm}(v_b, A \times A'; n, d \cdot d'; p, B \cdot |B'|)$.

(h) Let $C, a \in \mathbb{C}$, suppose $d \neq 0$, and let $z \in Z$ with $z \in \mathrm{Adm}((x \mapsto C \cdot v(x)), A; n, d; p, B)$. Then $\mathrm{nu}(aC/d) \cdot a \cdot z \in \mathrm{Adm}(v, A; n, 1; p, d \cdot B)$, where $\mathrm{nu}(w) = w^{-1}$ for $w \neq 0$ and $\mathrm{nu}(0) = 1$.

Proof. (a) Take the coefficients c on F and 0 elsewhere. (b) Take the coefficient 1 at x; the size is 1, and $d \cdot 1 \in O^{(n)}$. (c) Apply L to $z = \sum_x r(x)v(x)$. (d), (e), (f) follow from Theorem A(i), proved below without them. For (d): by (c), $c \cdot z \in \mathrm{Adm}((x \mapsto c \cdot v(x)), A; n, d; p, B)$, and each $c \cdot v(x)$ is the combination of the v's with the single coefficient c, which is admissible with denominator 1 and size 1; substitute. For (e): 0 and the roots of unity lie in $O^{(n)}$, since a ring homomorphism to a field sends a root of unity to a root of unity, of absolute value 1; the same holds for the automorphisms σ; apply (d). For (f): by (b) and (e), $v(x) \in \mathrm{Adm}(v', A'; n, 1; p, 1)$ for $x \in A$; substitute. (g) By (c) for the linear map $b(\,\cdot\,, z')$, $b(z, z') \in \mathrm{Adm}((x \mapsto b(v(x), z')), A; n, d; p, B)$. For $x \in A$, by (c) for $b(v(x), \cdot\,)$, the vector $b(v(x), z')$ is an admissible combination of the $b(v(x), v'(x'))$, $x' \in A'$, with denominator d' and size B', hence, each of these being a single vector of the family indexed by $A \times A'$, an admissible combination of that family; substitute. (h) Let $z = \sum_x r(x)\, C v(x)$ with r admissible. The coefficients $d \cdot r$ are admissible with denominator 1 and, under p, size $d \cdot B$; let $z_1 = \sum_x d\, r(x)v(x)$. If $aC \neq 0$ then $\mathrm{nu}(aC/d)\, a\, z = (d/(aC)) \cdot aC \sum_x r(x)v(x) = z_1$; if $aC = 0$ then $a\, z = 0$. In both cases $\mathrm{nu}(aC/d)\, a\, z = \varsigma z_1$ with $\varsigma \in \{0, 1\}$, and (e) applies. □

LEAN `IsAdmissibleComb.of_sum` · `IsAdmissibleComb.single` · `IsAdmissibleComb.map` · `IsAdmissibleComb.smul` · `IsAdmissibleComb.smul_of_eq_zero_or_isOfFinOrder` · `IsAdmissibleComb.of_eq_isOfFinOrder_smul` · `IsAdmissibleComb.map_bilinear` · `IsAdmissibleComb.normUnit_smul`

Proof of Theorem A. (i) Write $z = \sum_x c(x)v(x)$ with c admissible for $(A; n, d; p, B)$; for $x \in A$ write $v(x) = \sum_y r_x(y)v'(y)$ with r_x admissible for $(A'; n, d'; p, B')$; and write $d'' = d\, d'\, k$. Put $\rho = \sum_{x \in \mathrm{supp}\, c} c(x)\, r_x$, a finitely supported function on $\mathcal{X}'$. Then $z = \sum_y \rho(y)v'(y)$. The support of ρ lies in A', because the support of c lies in A and that of every r_x, $x \in A$, in A'. Next $d''\rho(y) = k \sum_x (d\, c(x))(d'\, r_x(y))$ is a sum of products of elements of the ring $O^{(n)}$. Finally suppose p and let σ be an automorphism of $\mathbb{C}$. Then $B \ge 0$, and

$$\sum_y |\sigma(\rho(y))| \le \sum_x |\sigma(c(x))| \sum_y |\sigma(r_x(y))| \le \sum_x |\sigma(c(x))| \cdot |B'| \le B \cdot |B'| \le C.$$

(ii) Write $z = \sum_x r(x)v(x)$ with r admissible. Then $d \cdot z = \sum_x (d\, r(x))\, v(x)$; each $d\, r(x)$ lies in $O^{(n)} \subseteq O_J$, as ℓ is coprime to n, and each $v(x)$ with $r(x) \neq 0$ has $x \in A$, so lies in M.

(iii) Induction on m. For $m = 0$ the pure tensor is $1 \in \mathbb{C}$, the single vector of the family at the tuple $y = 0$, whose entries lie in the subgroups A_j; use Lemma 3.1(b). For the step from m to $m+1$, apply Lemma 3.1(g) to the bilinear map $(f, f') \mapsto f \otimes f'$, to f_m (denominator d, size B) and to the pure tensor of $f_{m-1}, \dots, f_0$ (denominator d^m, size $|B|^m$, by induction): the pure tensor of $f_m, \dots, f_0$ is an admissible combination, with denominator d^{m+1} and size $|B|^{m+1}$, of the tensors $v_m(x) \otimes$ (pure tensor at y), for $x \in A_{2m} \times A_{2m+1}$ and y a tuple with entries in the A_j. Such a tensor is the vector of the family for $m+1$ at the tuple that agrees with y except at the places $2m$ and $2m+1$, where it has the entries of x; that tuple has its entries in the A_j. Lemma 3.1(f), with $\varsigma = 1$, re-indexes the combination. □

Lemma 3.2 (integrality away from n)**.** *(a) Let n, c, d, k be natural numbers such that c divides $d \cdot n^k$. Then $d/c \in O^{(n)}$.*

(b) Let E be a CM field with a CM type, I a finite index set, and n, m natural numbers that are coprime. If $g \in G_f(I)$ has $g_w \in \mathrm{GL}_I(O_w)$ at every finite place w that does not divide n, then $g_w \in \mathrm{GL}_I(O_w)$ at every finite place w that divides m; here O_w is the ring of integers at w.

(c) Let E carry Weil data, let ℓ be a prime number, $\jmath\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism, I a finite index set and $g \in G_f(I)$ integral above ℓ*: $g_w \in \mathrm{GL}_I(O_w)$ at every finite place w dividing ℓ. Then $|\jmath(\Delta_f(g))|_\ell = 1$.*

(d) Let E be a CM field with a CM type, ℓ, $\jmath$, I as in (c), $g \in G_f(I)$ integral above ℓ, and μ a character of $\mathrm{U}(1)(\mathbb{A})$, trivial on $\mathrm{U}(1)(E)$, that has a weight and a tame part in the sense of the note on the characters of the data. For any signs on I, with $\det(1, g)$ the determinant of the element $(1, g)$ of the adelic unitary group of these signs: $|\jmath(\mu(\det(1, g)))|_\ell = 1$.

Proof. (a) Let ℓ be a prime coprime to n and $\jmath\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism. Write $d\,n^k = c\,m$ with m a natural number. Since ℓ does not divide n, $|\jmath(n)|_\ell = 1$, so $|\jmath(d)|_\ell = |\jmath(c)|_\ell\,|\jmath(m)|_\ell$ and $|\jmath(d/c)|_\ell = |\jmath(m)|_\ell \le 1$, the image of a natural number being integral. (For $c = 0$ the quotient is 0 by convention, and the claim is trivial.) (b) A finite place that divides m does not divide n: its prime ideal would contain $1 \in m\mathbb{Z} + n\mathbb{Z}$. (c), (d) In the formal text each is proved by one call of the simplifier, which we did not expand. It unfolds $\Delta_f(g)$ into the value of the finite part of the splitting character, and of an absolute value, at the determinant of a matrix λ with $\lambda\hat{\mathcal{O}}^I = \hat{\mathcal{O}}^I \cap g^{-1}\hat{\mathcal{O}}^I$, which is a unit at the places above ℓ when g is integral there; and it unfolds $\mu(\det(1, g))$ into a product of values of the tame part and of the weight at the local determinants, which are units above ℓ. The lemmas of the library that say that such values are ℓ-adic units under $\jmath$ are quoted, not read. □

Lemma 3.3 (groups of translations)**.** *Let E be a CM field and n a natural number.*

(a) Let I, I_0 be finite index sets, M an $I \times I_0$ matrix over $\mathbb{A}_f$ with all entries in $\hat{\mathcal{O}}$, $d\colon I \to \mathbb{A}_f$ and $d'\colon I_0 \to \mathbb{A}_f$ families, and $y \in \mathrm{Tr}_n[d]$. Suppose that for all $i \in I$, $j \in I_0$ and every finite place w with $|d_{i,w}|_w \neq |d'_{j,w}|_w$ the component of M_{ij} at $\bar{w}$ is 0. Then $M^* y \in \mathrm{Tr}_n[d']$.

(b) Let I, X be index sets, $c \in \hat{\mathcal{O}}$, $d\colon I \to \mathbb{A}_f$ a family, $x \in \mathrm{Tr}_n[d]$ and $f\colon X \to I$ a map. Then the vector $(c \cdot \overline{x_{f(i)}})_{i\in X}$ lies in $\mathrm{Tr}_n[(\overline{d_{f(i)}})_{i\in X}]$.

Proof. (a) $(M^*y)_j = \sum_i \overline{M_{ij}}\, y_i$, and the conditions define a group, so fix i, j and a finite place w not dividing n. If $|d_{i,w}|_w = |d'_{j,w}|_w$, then $|d'_j \overline{M_{ij}} y_i|_w = |\overline{M_{ij}}|_w\, |d_i y_i|_w \le 1$. Otherwise M_{ij} vanishes at $\bar w$, so $\overline{M_{ij}}$ vanishes at w. (b) $|\overline{d_{f(i)}}\, c\, \overline{x_{f(i)}}|_w = |c|_w\, |d_{f(i)} x_{f(i)}|_{\bar w} \le 1$ for w not dividing n, since then $\bar w$ does not divide n either. □

LEAN `mulVec_mem_weightedTranslations` · `star_mem_weightedTranslations`

Proposition 3.4 (a moved translate of the vacuum)**.** *Let E carry Weil data and let V be a hermitian space with index set I and its signs. Let n, d be natural numbers, $g \in G_f(I)$, $x \in \mathbb{A}_f^I$, $A \subseteq \mathbb{A}_f^I$ a set, p a proposition and $C, c \in \mathbb{C}$. Suppose that $c \cdot C = \Delta_f(g)$; that $g(x+y) \in A$ for every $y \in \hat{\mathcal{O}}^I$; that $d \cdot c/|\Delta_f(g)|^2 \in O^{(n)}$; and that p implies $|\sigma(c)| \le 1$ for every automorphism σ. Then*

$$\omega_V(1,g)\, \varrho_{f,V}(x)\mathrm{vac}_V \in \mathrm{Adm}((z \mapsto C \cdot \varrho_{f,V}(z)\mathrm{vac}_V), A; n, d; p, 1).$$

Proof. By Input 1(b), (c) and (a),

$$\omega_V(1,g)\varrho_{f,V}(x)\mathrm{vac}_V = \varrho_{f,V}(gx)\, \omega_V(1,g)\mathrm{vac}_V = \frac{c\,C}{|\Delta_f(g)|^2} \sum_y \varsigma_y\, \varrho_{f,V}(g(x+y))\mathrm{vac}_V,$$

the sum over representatives y of the $|\Delta_f(g)|^2$ classes of $\hat{\mathcal{O}}^I$ modulo $\hat{\mathcal{O}}^I \cap g^{-1}\hat{\mathcal{O}}^I$, with roots of unity ς_y. This is a sum, over a finite set, of the vectors $C\varsigma_y \varrho_{f,V}(g(x+y))\mathrm{vac}_V$ with the constant coefficient $c/|\Delta_f(g)|^2$. Its d-fold lies in $O^{(n)}$ by hypothesis; under p the size is $|\Delta_f(g)|^2 \cdot |\sigma(c)|/|\Delta_f(g)|^2 \le 1$, the positive integer $|\Delta_f(g)|^2$ being fixed by σ. So Lemma 3.1(a) applies, and Lemma 3.1(f) replaces each vector by $C\varrho_{f,V}(z)\mathrm{vac}_V$ with $z = g(x+y) \in A$. □

LEAN `isAdmissibleComb_weil_vacElem`

4 Lattices of graded spaces

Proposition 4.1 (the graded lattice basis is unimodular)**.** *Let X, I be finite index sets, l and N natural numbers, R a commutative ring with an involution, $\mathbf{e}\colon X^+ \sqcup \{0,\dots,l-1\} \to I$ a bijection, S a commutative ring, R_0 a subring of R, $f\colon S \to R$ a ring homomorphism, a and π units of R and $u \in R$ with $u\bar u = 1$. Suppose $f(N) = \pi\bar\pi$. Then the matrix $\mathsf{L}_{\mathbf{e}}(a,\pi,u)^* \cdot f(\mathrm{Gr}_{\mathbf{e}}(N)) \cdot \mathsf{L}_{\mathbf{e}}(a,\pi,u)$ is hermitian and lies in $\mathrm{GL}_I(R_0)$: its entries and those of its inverse lie in R_0.*

Proof. Let g_i be the columns of the graded lattice basis and $\langle\,,\rangle$ the form of $f(\mathrm{Gr}_{\mathbf{e}}(N))$. For l even, $g_b = ua^{-1}e_b$ for $2b < l$ and $g_b = u\bar a e_b$ otherwise, so $\langle g_b, g_{l-1-b}\rangle = \overline{ua^{-1}}\, u\bar a = 1$ for $2b < l$, and the Gram matrix is $\mathrm{Gr}_{\mathbf{e}}(N)$ itself (there is no middle vector), a permutation matrix equal to its inverse. For l odd with middle index z: $\langle g_b, g_{l-1-b}\rangle = u\bar u = 1$ for $b \ne z$; $\langle g_z, g_z\rangle = -u\bar u f(N) = -f(N)$; $\langle g_{\mathrm{pt}}, g_z\rangle = \overline{u(\pi\bar\pi)^{-1}} \cdot (-f(N)) \cdot u = -1$; and $\langle g_{\mathrm{pt}}, g_{\mathrm{pt}}\rangle = (\pi\bar\pi)^{-1} - u\bar u f(N)(\pi\bar\pi)^{-2} = 0$. So the Gram matrix is the image of the integer matrix that agrees with $\mathrm{Gr}_{\mathbf{e}}(N)$ except for the entries 0 at $(\mathrm{pt},\mathrm{pt})$ and -1 at (pt, z) and (z, pt). On the span of e_{pt}, e_z it is $\left(\begin{smallmatrix} 0 & -1 \\ -1 & -N \end{smallmatrix}\right)$, with inverse $\left(\begin{smallmatrix} N & -1 \\ -1 & 0 \end{smallmatrix}\right)$; elsewhere it is a permutation matrix. Both matrices are hermitian with entries in the image of $\mathbb{Z}$, hence in R_0. □

LEAN `isUnimodular_gradedLatticeBasis_gram`

Proposition 4.2 (a real frame)**.** *Let X, I be finite index sets, l and N natural numbers, R a commutative ring, $\mathbf{e}\colon X^+ \sqcup \{0,\dots,l-1\} \to I$ a bijection and $\phi\colon R \to \mathbb{C}$ a ring homomorphism. Suppose $N > 0$, and let $\varepsilon\colon I \to \{\pm 1\}$ be signs with exactly $\lfloor (l+1)/2 \rfloor$ minus signs. Then there is a complex $I \times I$ matrix y with $y^* \phi(\mathrm{Gr}_{\mathbf{e}}(N)) y$ the diagonal matrix of ε, and with $y^* y = 1$ if $N = 1$.*

Proof. Let $\eta_b = -1$ for $b < \lfloor (l+1)/2 \rfloor$ and $\eta_b = 1$ for the other string indices. The signs equal to 1 on X^+ and to η on the string have $\lfloor (l+1)/2 \rfloor$ minus signs, like ε, so after a bijection of the index sets we may assume that they are ε. Let y be the identity on X^+ and have, at a string index b with $b' = l - 1 - b \neq b$, the column $y_b = (\eta_b e_b + e_{b'})/\sqrt{2}$, and at the middle index (if l is odd) the column $e_b/\sqrt{N}$. For $b \neq b'$ the form pairs e_b with $e_{b'}$ to 1, so $\langle y_b, y_b \rangle = \eta_b$ and $\langle y_b, y_{b'} \rangle = (\eta_b \eta_{b'} + 1)/2 = 0$, because exactly one of b, b' is smaller than $\lfloor (l+1)/2 \rfloor$. At the middle index $\langle y_b, y_b \rangle = -N/N = -1 = \eta_b$. If $N = 1$ the columns are orthonormal for the standard hermitian form: $|\eta_b|^2/2 + 1/2 = 1$, $(\eta_b + \eta_{b'})/2 = 0$, and $1/N = 1$. □

LEAN `exists_frame_gradedGram`

Lemma 4.3 (vectors in the lattice)**.** *Let E be a CM field with a CM type, V a hermitian space with index set I and its signs, and $\mathcal{Y}$ a grading of V of norm N with definite part X^+ and a string of odd length l. Let a, π be finite ideles and u a finite adele with $u\bar{u} = 1$ such that $\mathsf{Lat}(\mathcal{Y}; a, \pi, u)$. Let $c \in \hat{\mathcal{O}}$, and let $x\colon X^+ \to \mathbb{A}_f$ be a vector with $x_i \in \hat{\mathcal{O}}$ for $i \in X$ and $\bar{\pi} x_{\mathrm{pt}} \in \hat{\mathcal{O}}$. Let $v \in \mathbb{A}_f^I$ be the vector with the coordinates x_i at the indices of X^+, $u(\pi^{-1} x_{\mathrm{pt}} + c)$ at the middle string index and 0 at the other string indices. Then every coordinate $(x_{V,f}^{-1} v)_i$, $i \in I$, lies in $\hat{\mathcal{O}}$.*

Proof. Write $x_{V,f} = \mathsf{L}_{\mathbf{e}_y}(a, \pi, u) \cdot k$ with $k \in \mathrm{GL}_I(\hat{\mathcal{O}})$. Let w be the vector with coordinates x_i at $i \in X$, $\bar{\pi} x_{\mathrm{pt}}$ at pt, c at the middle index z and 0 elsewhere; it is integral. By Definition 2.11, for odd l,

$$\mathsf{L}_{\mathbf{e}_y}(a, \pi, u)\, w = \sum_{i \in X} x_i e_i + \bar{\pi} x_{\mathrm{pt}} (\bar{\pi}^{-1} e_{\mathrm{pt}} + u(\pi\bar{\pi})^{-1} e_z) + c\, u\, e_z = v.$$

Hence $x_{V,f}^{-1} v = k^{-1} w$ is integral. □

LEAN `inv_xFin_mulVec_mem_of_spansLattice`

5 The finite zero term

Proposition 5.1. *Let E carry Weil data and let Ξ be a splitting of V over V_0 along H, with index sets I, I_0 and their signs.*

(i) ev_Ξ^f *maps $\mathcal{W}_f(V)$ into $\mathcal{W}_f(V_0)$.*

(ii) For every adelic vector $y \in \mathbb{A}^I$ and every $v \in \mathcal{F}(V)$ there is $v_0 \in \mathcal{F}(V_0)$ such that, for all $f \in \mathcal{S}(V)$,

$$\mathrm{ev}_\Xi(\varrho_V(y)(v \otimes f)) = v_0 \otimes \mathrm{ev}_\Xi^f(\varrho_{f,V}(y_f) f).$$

(iii) Let $b \in \mathbb{A}_f^H$, $w \in \mathbb{A}_f^{I_0}$ and $z = \mathsf{i}_{\Xi,f} w + \mathsf{k}_{\Xi,f} b$. Then, for every $f \in \mathcal{S}(V)$,

$$\mathrm{ev}_\Xi^f(\varrho_{f,V}(z) f) = \varrho_{f,V_0}(w)\ \mathrm{ev}_\Xi^f(f).$$

Proof. Let $g = (g_\infty, g_f)$ be the adapted element chosen in Definition 2.12, so that, by Input 1(b), $v_\Xi \otimes f = \omega_V(g)(v_{\mathrm{vac}} \otimes \omega_V(1, g_f^{-1}) f)$.

(iii) $\varrho_{f,V}(z)$ is a root of unity times the Heisenberg operator at the adelic vector with real part 0 and finite part αz, which in frame coordinates is the sum of an i-part and a k-part. Finite translations commute with $v_\Xi \otimes$, and Input 3(b) moves them through the zero term: the k-part disappears and the i-part becomes the translation by αw. Since k is isotropic and orthogonal to i, $z^*z = w^*w$, so the root of unity in $\varrho_{f,V}(z)$ is that of $\varrho_{f,V_0}(w)$ and the two translations commute without a factor.

(i) Let $f \in \mathcal{W}_f(V)$. Then $f_1 = \omega_V(1, g_f^{-1})f \in \mathcal{W}_f(V)$ and $v_{\mathrm{vac}} \otimes f_1 = f_1$ (Inputs 1(b), 3(a)), so $\mathrm{ev}^f_\Xi(f) = \mathrm{ev}_\Xi(\omega_V(g)f_1)$, and it suffices to see that $\mathrm{ev}_\Xi \circ \omega_V(g)$ maps every $\varrho_{f,V}(x)\mathrm{vac}_V$ into $\mathcal{W}_f(V_0)$. By Input 1(b), $\omega_V(g)\varrho_{f,V}(x)\mathrm{vac}_V = \varrho_{f,V}(g_f x)\omega_V(g)\mathrm{vac}_V$. Decompose $g_f x$ along the finite frame as in Input 3(c), into an l-part, an i-part with coordinates w and a k-part. By Input 3(b) the zero term turns the translation by the i-part into $\varrho_{f,V_0}(w)$ and forgets the k-part, up to roots of unity, and by Input 3(a) what remains, the zero term of an l-translate of $\omega_V(g)\mathrm{vac}_V$, is a multiple of vac_{V_0}. So the result is a multiple of $\varrho_{f,V_0}(w)\mathrm{vac}_{V_0}$.

(ii) By Input 1(b), $\varrho_V(y)(v \otimes f) = v_1 \otimes f_2$ with $f_2 = \varrho_{f,V}(y_f)f$ and some $v_1 \in \mathcal{F}(V)$. Again by Input 1(b), $v_1 \otimes f_2 = \omega_V(g)((\omega_V(g_\infty)^{-1}v_1) \otimes \omega_V(1, g_f^{-1})f_2)$. Input 3(a) gives

$$\mathrm{ev}_\Xi(v_1 \otimes f_2) = \Lambda(\omega_V(g_\infty)^{-1}v_1) \otimes \mathrm{ev}_\Xi(\omega_V(g)(v_{\mathrm{vac}} \otimes \omega_V(1, g_f^{-1})f_2)) = v_0 \otimes \mathrm{ev}^f_\Xi(f_2),$$

with $v_0 = \Lambda(\omega_V(g_\infty)^{-1}v_1)$. □

LEAN zeroTermFin_spec · zeroTermFin_finHeisOp_finFrameVector

Proposition 5.2 (the frequency of a non-zero finite zero term)**.** *Let E carry Weil data and let Ξ be a splitting of V over V_0 along H, with index sets I, I_0 and their signs. Let M, M' be $I \times I$ matrices over $\mathbb{A}_f$ with $M \cdot M'^* = 1$, let $f \in \mathcal{S}(V)$ with $\varrho_{f,V}(Mx)f = f$ for every $x \in \hat{\mathcal{O}}^I$, and let $y \in \mathbb{A}_f^I$ with $\mathrm{ev}^f_\Xi(\varrho_{f,V}(y)f) \neq 0$. Then there is $x_0 \in \hat{\mathcal{O}}^I$ with $\mathsf{k}^*_{\Xi,f}(y - M'x_0) = 0$.*

Proof. The $I \times H$ matrix $M'^*\mathsf{k}_{\Xi,f}$ has a left inverse: if c is the matrix that reads off the k-coordinate (Input 3(c)), then $\mathsf{c}MM'^*\mathsf{k}_{\Xi,f} = \mathsf{c}\mathsf{k}_{\Xi,f} = 1$. By Hermite reduction over $(\mathbb{A}_f, \hat{\mathcal{O}})$ (Input 6) there is an invertible $H \times H$ matrix t over $\mathbb{A}_f$ such that $M'^*\mathsf{k}_{\Xi,f}t$ has entries in $\hat{\mathcal{O}}$ and a left inverse L with entries in $\hat{\mathcal{O}}$. Put $u = t^*\mathsf{k}^*_{\Xi,f}y$ and $x_0 = L^*u$.

We claim $u \in \hat{\mathcal{O}}^H$; by Input 1(e) it suffices that $\psi_0(x^*u) = 1$ for $x \in \hat{\mathcal{O}}^H$. For such x, the vector $M'^*\mathsf{k}_{\Xi,f}tx$ is integral, so, by the hypothesis on f and $MM'^* = 1$, $\varrho_{f,V}(\mathsf{k}_{\Xi,f}tx)f = f$. By Input 1(e), $\varrho_{f,V}(y)f = \varrho_{f,V}(y)\varrho_{f,V}(\mathsf{k}_{\Xi,f}tx)f = \psi_0(x^*u) \cdot \varrho_{f,V}(\mathsf{k}_{\Xi,f}tx)\varrho_{f,V}(y)f$. Apply ev^f_Ξ; by Proposition 5.1(iii), with $w = 0$, the translation along k disappears: $\mathrm{ev}^f_\Xi(\varrho_{f,V}(y)f) = \psi_0(x^*u) \cdot \mathrm{ev}^f_\Xi(\varrho_{f,V}(y)f)$. As this vector is not zero, $\psi_0(x^*u) = 1$.

So $x_0 \in \hat{\mathcal{O}}^I$, and $t^*\mathsf{k}^*_{\Xi,f}(y - M'x_0) = u - (LM'^*\mathsf{k}_{\Xi,f}t)^*u = 0$; as t^* is invertible, the claim follows. □

LEAN zeroTermFin_support

Proposition 5.3 (the finite zero term of a translated vacuum)**.** *Let E carry Weil data and let Ξ be a splitting of V over V_0 along H, with index sets I, I_0 and their signs. Let $g \in G_f(I_0)$, let c be an $H \times I_0$ matrix over $\mathbb{A}_f$, and suppose that the matrix*

$B = \mathsf{i}_{\Xi,f}\, g + \mathsf{k}_{\Xi,f}\, c$ *has all its entries in* $\hat{\mathcal{O}}$. *Then there is* $C \in \mathbb{C}$ *such that for every* $y \in \mathbb{A}_f^I$ *there is* $\varsigma \in \mathbb{C}$, *zero or a root of unity, with*

$$\mathrm{ev}_\Xi^f(\varrho_{f,V}(y)\mathrm{vac}_V) = \varsigma \cdot C \cdot \omega_{V_0}(1,g)\, \varrho_{f,V_0}(B^* y)\mathrm{vac}_{V_0}.$$

Proof. *The constant.* $f_0 = \mathrm{ev}_\Xi^f(\mathrm{vac}_V)$ lies in $\mathcal{W}_f(V_0)$ (Proposition 5.1(i)). For $x \in \hat{\mathcal{O}}^{I_0}$, by Proposition 5.1(iii) with $w = gx$ and $b = cx$, $\varrho_{f,V_0}(gx) f_0 = \mathrm{ev}_\Xi^f(\varrho_{f,V}(Bx)\mathrm{vac}_V) = f_0$, as $Bx \in \hat{\mathcal{O}}^I$ (Input 1(a)). By Input 1(d), $f_0 = C \cdot \omega_{V_0}(1,g)\mathrm{vac}_{V_0}$ for some C.

The identity. Fix y. If $\mathrm{ev}_\Xi^f(\varrho_{f,V}(y)\mathrm{vac}_V) = 0$, take $\varsigma = 0$. Otherwise Proposition 5.2, with $M = M' = 1$ and $f = \mathrm{vac}_V$, gives $x_0 \in \hat{\mathcal{O}}^I$ with $\mathsf{k}_{\Xi,f}^*(y - x_0) = 0$. By Input 3(c), $y - x_0 = \mathsf{i}_{\Xi,f} w + \mathsf{k}_{\Xi,f} b$ with $w = \mathsf{i}_{\Xi,f}^*(y - x_0)$. Hence, with roots of unity ς_1, ς_2 from Input 1(a),

$$\begin{aligned}\mathrm{ev}_\Xi^f(\varrho_{f,V}(y)\mathrm{vac}_V) &= \mathrm{ev}_\Xi^f(\varrho_{f,V}(y)\varrho_{f,V}(-x_0)\mathrm{vac}_V) = \varsigma_1\, \mathrm{ev}_\Xi^f(\varrho_{f,V}(y - x_0)\mathrm{vac}_V)\\ &= \varsigma_1 \varrho_{f,V_0}(w) f_0 = \varsigma_1 C\, \varrho_{f,V_0}(w)\omega_{V_0}(1,g)\mathrm{vac}_{V_0}.\end{aligned}$$

Since g is unitary and $\mathsf{k}_{\Xi,f}^*(y - x_0) = 0$, we have $gB^*(y - x_0) = gg^*\mathsf{i}_{\Xi,f}^*(y - x_0) = w$, so by Input 1(b) $\varrho_{f,V_0}(w)\omega_{V_0}(1,g) = \omega_{V_0}(1,g)\varrho_{f,V_0}(B^*(y - x_0))$; and $B^* x_0 \in \hat{\mathcal{O}}^{I_0}$ fixes the vacuum, so $\varrho_{f,V_0}(B^*(y - x_0))\mathrm{vac}_{V_0} = \varsigma_2 \varrho_{f,V_0}(B^* y)\mathrm{vac}_{V_0}$. Take $\varsigma = \varsigma_1\varsigma_2$. □

6 Arrow pairs

Lemma 6.1 (two computations in rational coordinates)**.** *Let E be a CM field with a CM type and V, V' hermitian spaces with index sets I, I' and their signs.*

(a) For a pair $g = (g_1, g_2)$ of elements of $G(V)$ and $G(V')$, the matrix in rational coordinates of $g_1 \oplus g_2$, an element of $G(V \oplus V')$, is the block diagonal matrix of those of g_1 and g_2.

(b) Let $\mathcal{Y}$, $\mathcal{Y}'$ be gradings of V, V' of norm N, with definite parts X, X' and strings of lengths l, l'. For $g \in G(\langle X\rangle)$ and $g' \in G(\langle X'\rangle)$, in rational coordinates, $\imath_{\mathcal{Y}'}(g') \cdot T_{\mathcal{Y},\mathcal{Y}'} \cdot \imath_{\mathcal{Y}}(g)^{-1} = T_{\mathcal{Y},\mathcal{Y}'}$.

Proof. (a) The frame of $V \oplus V'$ is block diagonal. (b) In rational coordinates $\imath_{\mathcal{Y}}(g)$ is block diagonal for the decomposition into X and the string, with the identity on the string, and likewise $\imath_{\mathcal{Y}'}(g')$; the string map has its only non-zero block from string to string. □

LEAN `ratCoordMatrix_sum` · `inclX_mul_stringMap_mul_inclX_inv`

Lemma 6.2. *In Setting 2.6, let X'', H be finite index sets and $\mathcal{R} \in \mathrm{Arr}_{X'',H}(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}'')$. For all $\Phi \in \mathcal{W}_f(\mathrm{Hom}(V, V'))$ and $\Phi' \in \mathcal{W}_f(\mathrm{Hom}(V', V''))$,*

$$\mathrm{at}(\mathrm{fev}_{\mathcal{R}}(\Phi \boxtimes \Phi')) = \mathrm{ev}_{\Xi^{\mathrm{pr}}(\mathcal{R})}^f\Big(\varrho_f(\mathbf{T}_f(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}''))(\Phi \boxtimes \Phi')\Big),$$

where at *is the map of the standard spaces $\langle X\rangle$, $\langle X'\rangle$, $\langle X''\rangle$.*

Proof. $\Phi \boxtimes \Phi' = \mathrm{at}(\Phi \otimes \Phi')$ lies in $\mathcal{W}_f(\mathrm{Hom}(V', V^- \oplus V''))$ (Input 2(e)); the finite Heisenberg operators preserve finite parts (Input 1(a)); and $\mathrm{ev}_{\Xi^{\mathrm{pr}}(\mathcal{R})}^f$ maps finite parts to finite parts (Proposition 5.1(i)). So the right side lies in $\mathcal{W}_f(\mathrm{Hom}(\langle X'\rangle, \langle X\rangle^- \oplus \langle X''\rangle))$, which is the range of at for the standard spaces, and $\mathrm{at} \circ \mathrm{at}^\flat$ is the identity on that range because $\mathrm{at}^\flat \circ \mathrm{at} = 1$. □

Proof of Theorem B. (i) Put $\mathrm{wt} = \mathrm{gr}_y \sqcup \mathrm{gr}_{y''}$, write $l' = 2j$ (possible as l is odd and $l' = l-1$), let m_+ be the number of indices of $I \sqcup I''$ of positive weight, and let $x = \imath_y(g)^- \oplus \imath_{y''}(k) \in G(V^- \oplus V'')$. In rational coordinates x is the identity on the basis vectors of non-zero weight, because $\imath_y$ and $\imath_{y''}$ fix the string vectors (Lemma 6.1(a)). The splitting $\Xi^{\mathrm{pr}}(\mathcal{R})$ is a composite, so its zero term is the composite of two zero terms (Definition 2.4), and $\omega^{\mathrm{tr}}_{\mu,\mu'}(\imath_y g, \imath_{y'} g', \imath_{y''} k)$ is a scalar c_V times the Weil operator of $(\imath_{y'}(g'), x)$ on $\mathrm{Hom}(V', V^- \oplus V'')$ (Definition 2.3).

First zero term. Apply Input 3(d) to the splitting $\Xi(\mathcal{Z}^{\mathrm{Hom}}(\mathcal{R}))$, whose frame k consists of the basis vectors (i, b) of positive degree $\mathrm{wt}(i) - \mathrm{gr}_{y'}(b)$, with the element $(\imath_{y'}(g'), x)$, the element $g_0 = (g', 1 \oplus g^- \oplus \mathrm{emb}_{\mathcal{R}}(k))$ of the group of the zero part, and the matrix C that acts by x on the rows above each $b \in I'$ of negative grade and by the inverse transpose of $\imath_{y'}(g')$ on the columns above each i of positive weight, and is the identity elsewhere. Its determinant is $u = (\det g \cdot \det k)^j \cdot (\det g')^{-m_+}$, since y' has j string vectors of negative grade, $\det x = \det g \cdot \det k$ and $\det \imath_{y'}(g') = \det g'$. The conditions of Input 3(d) are statements about the entries of block diagonal matrices: they hold because x is the identity off weight zero, because the zero part has degree zero only above X' (Definition 2.14), and, for the last one, by condition (c) of Definition 2.16. Hence the first zero term carries the Weil operator of $(\imath_{y'}(g'), x)$ to $\upsilon(u)^{-1}$ times that of g_0.

Second zero term. By Input 3(e), removing the H planes carries the Weil operator of $(g', 1 \oplus g^- \oplus \mathrm{emb}_{\mathcal{R}}(k))$ to $\upsilon(\det g')^{|H|}$ times that of $(g', g^- \oplus \mathrm{emb}_{\mathcal{R}}(k))$; the side conditions of the input hold for the explicit frames of the splitting that removes the planes.

The scalars. The right side of (i) is the scalar c_X of the triple action for the standard spaces $\langle X\rangle$, $\langle X'\rangle$, $\langle X''\rangle$ at $(g, g', \mathrm{emb}_{\mathcal{R}}(k))$ times the same Weil operator. So it remains to see $c_V = c_X \cdot \upsilon(u)\, \upsilon(\det g')^{-|H|}$. The values of μ and μ' in c_V and c_X agree, since $\det \imath_y(g) = \det g$ and $\det \mathrm{emb}_{\mathcal{R}}(k) = \det k$. It remains to compare the exponents of υ at the three determinants, with $\mu_V = \mu \upsilon^{\lfloor |I|/2 \rfloor}$. At $\det g$: $(|I'| - \lfloor |I'|/2 \rfloor) - (|X'| - \lfloor |X'|/2 \rfloor) = 2j - j = j$, as $|I'| = |X'| + 2j$. At $\det k$: $\lfloor |I'|/2 \rfloor - \lfloor |X'|/2 \rfloor = j$. At $\det g'$: counting the weights of $I \sqcup I''$, $|I| + |I''| = 2m_+ + 2|H| + |X| + |X''|$; this number is even by condition (b) of Definition 2.16, so $\lfloor |I|/2 \rfloor - \lfloor |I''|/2 \rfloor = (|I| - |I''|)/2$ and likewise for X, X'', and the exponent is

$$\tfrac{1}{2}(|I| - |I''|) - |I| - \tfrac{1}{2}(|X| - |X''|) + |X| = -\tfrac{1}{2}(|I| + |I''|) + \tfrac{1}{2}(|X| + |X''|) = -m_+ - |H|.$$

These are the exponents of $\upsilon(u)\upsilon(\det g')^{-|H|}$.

(ii) Since $\mathrm{at}^\flat \circ \mathrm{at} = 1$, Input 2(d), Lemma 6.2 and the hypothesis $\mathrm{emb}_{\mathcal{R}}(1, k) = (1, k')$ give for the right side

$$\mathrm{at}^\flat\Big(\omega^{\mathrm{tr}}_{\mu,\mu'}((1, g), (1, g'), \mathrm{emb}_{\mathcal{R}}(1, k))\ \mathrm{ev}^f_{\Xi^{\mathrm{pr}}(\mathcal{R})}(\varrho_f(\mathbf{t})(\Phi \boxtimes \Phi'))\Big), \qquad \mathbf{t} = \mathbf{T}_f(y, y', y'').$$

Now $\mathrm{ev}^f_{\Xi^{\mathrm{pr}}(\mathcal{R})}(F) = \mathrm{ev}_{\Xi^{\mathrm{pr}}(\mathcal{R})}(v \otimes F)$ for a fixed real datum v, and the triple action of finite points commutes with $v \otimes$ (Input 1(b)). So part (i), with $\imath^f_{y''}(k) = x$, turns this into the first of the two vectors

$$\mathrm{at}^\flat\ \mathrm{ev}^f_{\Xi^{\mathrm{pr}}(\mathcal{R})}(\omega^{\mathrm{tr}}_{\mu,\mu'}(\imath^f_y g, \imath^f_{y'} g', x)\, \varrho_f(\mathbf{t})(\Phi \boxtimes \Phi')),$$
$$\mathrm{at}^\flat\ \mathrm{ev}^f_{\Xi^{\mathrm{pr}}(\mathcal{R})}(\varrho_f(\mathbf{t})\, \omega^{\mathrm{tr}}_{\mu,\mu'}(\imath^f_y g, \imath^f_{y'} g', x)(\Phi \boxtimes \Phi')),$$

and by Input 2(d) the left side of (ii) is the second. The two agree: on an arrow product the translation by the stacked string map is the arrow product of the translations by the finite parts of the two string maps (Input 2(b)), the triple action is the arrow product of the two pair actions (Input 2(d)), and each pair action commutes with the translation by its string map by Input 2(g) and Lemma 6.1(b). □

7 Two unfolding steps

Proof of Theorem C(i). Let $z_0 \neq 0$ be the constant of Input 2(a) for V, V', V''. Let C_1 be the constant of Input 4(a) for $\mathcal{Y}$ and the set of all its indices of grade 1; this set is empty, the grades of $\mathcal{Y}$ being even. Let C_2 be the constant of Input 4(a) for $\mathcal{Y}'$ and the injection $\gamma_{\mathcal{X}}$. We show the claim with $z = C_1 C_2 z_0^{-1}$. Fix μ, μ', f, f', k, h and a generic P, and put

$$F(g,r) = P(gh)\ \mathrm{ct}^{\mu}_{y,y'}(f)(g,r)\ \mathrm{ct}^{\mu'}_{y',y''}(f')(r, \imath_{y''}(k)).$$

It is continuous, and invariant under the rational points of $B(\mathcal{Y})$ in g and of $B(\mathcal{Y}')$ in r (Input 4(c)).

Step 1: a product of two constant terms is a zero term. For data f_1, f_2 and matrices $y\colon V \to V'$, $y'\colon V' \to V''$ in rational coordinates, the product of the constant term of f_1 at y and of f_2 at y' equals $z_0^{-1} \cdot \mathrm{ev}_{\Xi_1}(\varrho(y) f_1 \boxtimes \varrho(y') f_2)(0)$, where $\Xi_1 = \Xi(\mathcal{Z}^{\mathrm{Hom}}(\mathcal{R}))$. Indeed, the value at 0 of this zero term is the mean of the datum over the matrices $V' \to V^- \oplus V''$ of positive degree (Definition 2.4). The map $(a,b) \mapsto \left(\begin{smallmatrix} a^\dagger \\ b \end{smallmatrix}\right)$ carries the pairs of a matrix $V \to V'$ and a matrix $V' \to V''$, both of positive degree, onto these matrices, because the adjoint exchanges the positions (b,a) and (a,b) up to the reversal of the strings, which changes the sign of both grades. So the mean is an iterated mean (Input 7(c)); by Input 2(b) and (a) the integrand is $\theta(\varrho(a)\varrho(y) f_1 \boxtimes \varrho(b)\varrho(y') f_2) = z_0\, \theta(\varrho(a)\varrho(y) f_1)\, \theta(\varrho(b)\varrho(y') f_2)$, and the two means of the factors are the two constant terms (Definition 2.5).

Step 2: the inner integral. Fix r. For a unipotent element n of $\mathcal{Y}$, $n-1$ raises grades by at least 2, the grades being even; so by Input 4(b) at $y = T_{y,y'}$, where the quotient of the two values of the bicharacter is 1, $F(n\,\imath_y(a), r) = F(\imath_y(a), r)$ for $a \in G(\langle X \rangle)$ (the second constant term does not involve n). Input 4(a), with the constant function of mean $F(\imath_y(a), r)$, gives $\int_{[B(\mathcal{Y})]} F(g,r)\, dg = C_1 \int_{[G(\langle X \rangle)]} F(\imath_y(a), r)\, da$.

Step 3: Fubini. The function $(a,r) \mapsto F(\imath_y(a), r)$ is continuous and invariant on a product of two compact quotients, so the integrals over r and a may be exchanged.

Step 4: the integral over $[B(\mathcal{Y}')]$. Fix $a \in G(\langle X \rangle)$ and let $g' \in G(\langle X' \rangle)$ and n' a unipotent element of $\mathcal{Y}'$. Put $f_1 = \omega^{\mathrm{pr}}_{\mu}(\imath_y a, \imath_{y'} g') f$ and $f_2 = \omega^{\mathrm{pr}}_{\mu'}(\imath_{y'} g', \imath_{y''} k) f'$. By Input 4(c) the two constant terms in $F(\imath_y(a), n' \imath_{y'}(g'))$ are the constant terms of f_1 at $n'^{-1} T_{y,y'}$ and of f_2 at $T_{y',y''} n'$. Since n' is unitary, $(n'^{-1} T_{y,y'})^\dagger = T^\dagger_{y,y'} n'$, so by Step 1 and Input 2(b)

$$F(\imath_y(a), n' \imath_{y'}(g')) = P(\imath_y(a) h) \cdot z_0^{-1} \cdot \mathrm{ev}_{\Xi_1}\Big(\varrho(\mathbf{T} + \mathbf{T}(n'-1))(f_1 \boxtimes f_2)\Big)(0),$$

where we write $\mathbf{T}$ for $\mathbf{T}(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}'')$. The matrix $\mathbf{T}(\mathcal{Y}, \mathcal{Y}', \mathcal{Y}'')(n'-1)$ has two kinds of entries. Outside the positions of degree zero, which are the positions $(\mathrm{ind}_{\mathcal{X}}(a'), x')$

with $x' \in X'$, it has entries only in positions of positive degree, because the string maps lower degrees by at most one and $n'-1$ raises them; translations in these directions do not change the zero term (Input 3(b)). At the positions of degree zero, condition (d) of Definition 2.16 shows that its entries are those of $\mathrm{inc}_{\mathcal{R}}$ applied to the vector that has, at the second copy of $k \in H$ and at $x' \in X'$, the entry of $\mathfrak{c}(\mathcal{Y}')(n'-1)$ at $(\gamma_{\mathcal{R}}(k), x')$, and zeros elsewhere. By Input 3(b) the zero term turns this translation into the translation of the zero part by that vector. No Heisenberg factor arises when $\varrho(\mathbf{T}+\mathbf{T}(n'-1))$ is split into $\varrho(\mathbf{T})$ and the translations by the two parts of $\mathbf{T}(n'-1)$: such factors are values of the Heisenberg bicharacter of $\mathrm{Hom}(V', V^- \oplus V'')$ (Definition 2.5), and two of them occur. First, $\varrho(\mathbf{T}(n'-1)+\mathbf{T})$ and $\varrho(\mathbf{T}(n'-1))\,\varrho(\mathbf{T})$ differ by the value $\mathrm{bi}(\mathbf{T}(n'-1), \mathbf{T}) = \psi_{\mathbb{A}}(\frac{1}{2}\mathbf{j}\,\mathrm{tr}(\mathbf{T}^\dagger \mathbf{T}(n'-1)))$, which is 1 because the stacked string map is isotropic:

$$\mathbf{T}^\dagger \mathbf{T} = -T_{y,y'}\,T_{y,y'}^\dagger + T_{y',y''}^\dagger\,T_{y',y''} = -\mathrm{sh}_{y'} + \mathrm{sh}_{y'} = 0.$$

Here the adjoint of the stacked matrix has the blocks $-T_{y,y'}$ and $T_{y',y''}^\dagger$, the sign being that of the form of V^-; the second product is $\mathrm{sh}_{y'}$ by Input 4(d) for the gradings $\mathcal{Y}'$, $\mathcal{Y}''$, and the first is $\mathrm{sh}_{y'}$ by Input 4(d) for $\mathcal{Y}$, $\mathcal{Y}'$ because $\mathfrak{c}(\mathcal{Y}') = \mathfrak{c}(\mathcal{Y})$, condition (b) of Definition 2.16. This is where that condition on an arrow pair is used. Second, the translation by $\mathbf{T}(n'-1)$ and the product of the translations by its part of positive degree and by its part of degree zero differ by the value of the bicharacter at these two parts. The first part lies along the isotropic frame k of Ξ_1 and the second along i, and the bicharacter pairs k only with l; so this value is 1. The directions of the vectors of degree zero are exactly those over which the splitting that removes the planes averages. Therefore $n' \mapsto F(\imath_y(a), n'\imath_{y'}(g'))$ is a continuous periodic function of the entries of $\mathfrak{c}(\mathcal{Y}')(n'-1)$ in the rows $\gamma_{\mathcal{R}}(H)$ and the columns X', and its mean is

$$M(g') = P(\imath_y(a)h)\cdot z_0^{-1}\cdot\theta\Big(\mathrm{ev}_{\Xi^{\mathrm{pr}}(\mathcal{R})}(\varrho(\mathbf{T}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}''))(f_1\boxtimes f_2))\Big).$$

Now $f_1\boxtimes f_2 = \omega^{\mathrm{tr}}_{\mu,\mu'}(\imath_y a, \imath_{y'}g', \imath_{y''}k)(f\boxtimes f')$ (Input 2(d)); this triple action commutes with $\varrho(\mathbf{T}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}''))$, as in the proof of Theorem B(ii); and Theorem B(i) moves it through the zero term. So

$$M(g') = P(\imath_y(a)h)\,z_0^{-1}\,\theta\Big(\omega^{\mathrm{tr}}_{\mu,\mu'}(a, g', \mathrm{emb}_{\mathcal{R}}(k))\ \mathrm{ev}_{\Xi^{\mathrm{pr}}(\mathcal{R})}(\varrho(\mathbf{T})(f\boxtimes f'))\Big),$$

a continuous function of g', left invariant under $\Gamma(\langle X'\rangle)$ by Input 2(f). Input 4(a) for $\mathcal{Y}'$ gives $\int_{[B(\mathcal{Y}')]} F(\imath_y(a), r)\,dr = C_2\int_{[G(\langle X'\rangle)]} M(g')\,dg'$. Together with Steps 2 and 3 this is the claim. □

LEAN `ArrowPair.integral_constTermAtT_mul`

Proof of Theorem C(ii). Let $z_0 \neq 0$ be the constant of Input 2(a) for the standard spaces $\langle X\rangle$, $\langle X'\rangle$, $\langle X_0\rangle$. For $o \in U$, φ, g and a datum f of $\mathrm{Hom}(\langle X'\rangle, \langle X\rangle^- \oplus \langle X_0\rangle)$, the function $(x,r) \mapsto \mathrm{coef}_t(\varphi)(x)\cdot\theta(\omega^{\mathrm{tr}}_{\mu_o,\mu'_o}(x,r,g)f)$ on $[G(\langle X\rangle)]\times[G(\langle X'\rangle)]$ is continuous and well defined (Inputs 5 and 2(f)), on a compact space since the standard spaces are definite; so it is integrable, and its integral $\mathcal{J}_{o,\varphi,g}(f)$ is a continuous linear functional of f.

Reduction to polynomial vectors. The real data u for which the theorem holds form a linear subspace of the Fock space. It is closed: the map sending u to the function $(o,y,\varphi,g) \mapsto \mathcal{J}_{o,\varphi,g}(u\otimes \mathrm{at}(y))$ is continuous for pointwise convergence,

and the functions of the form $(o, y, \varphi, g) \mapsto \mathrm{coef}_{t''}(\mathcal{L}''_o(y)\varphi)(g)$, t'' in the finite-dimensional dual of the vectors of weight $\varkappa$, form a finite-dimensional, hence closed, subspace. By Input 7(a) it suffices to treat $u = v_Q$, and by Input 7(b) and linearity a product $Q = Q_1 Q_2$ of a polynomial Q_1 in the coordinates of $\mathrm{Hom}(\langle X'\rangle, \langle X\rangle^-)$ and a polynomial Q_2 in those of $\mathrm{Hom}(\langle X'\rangle, \langle X_0\rangle)$.

Products. For such Q the polynomial vector is an arrow product of real data, $v_Q = v_{Q'_1} \boxtimes v_{Q_2}$, where Q'_1 is Q_1 transported to the coordinates of $\mathrm{Hom}(\langle X\rangle, \langle X'\rangle)$ (Input 2(h)). Let t' be the functional that Input 5 gives for $(\mathcal{L}_o)_o$, Q'_1 and t, and t'' the one for $(\mathcal{L}'_o)_o$, $z_0 Q_2$ and t'. By linearity in y it suffices to take $y = \Phi \otimes \Phi'$. Then $v_Q \otimes \mathrm{at}(y) = (v_{Q'_1} \otimes \Phi) \boxtimes (v_{Q_2} \otimes \Phi')$, again by Input 2(h), and by Input 2(d) and (a)

$$\theta(\omega^{\mathrm{tr}}_{\mu_o,\mu'_o}(x, r, g)(v_Q \otimes \mathrm{at}(y))) = z_0 \cdot \theta(\omega^{\mathrm{pr}}_{\mu_o}(x, r)(v_{Q'_1} \otimes \Phi)) \cdot \theta(\omega^{\mathrm{pr}}_{\mu'_o}(r, g)(v_{Q_2} \otimes \Phi')).$$

Integrating first over x (Fubini) and using the property of $\mathcal{L}_o$, then over r and using that of $\mathcal{L}'_o$, we get

$$\begin{aligned} \mathcal{J}_{o,\varphi,g}(v_Q \otimes \mathrm{at}(y)) &= \int_{[G(\langle X'\rangle)]} \mathrm{coef}_{t'}(\mathcal{L}_o(\Phi)\varphi)(r)\, \theta(\omega^{\mathrm{pr}}_{\mu'_o}(r, g)(v_{z_0 Q_2} \otimes \Phi'))\, dr \\ &= \mathrm{coef}_{t''}(\mathcal{L}'_o(\Phi')\mathcal{L}_o(\Phi)\varphi)(g). \end{aligned}$$

8 Admissible evaluations

Proposition 8.1 (the standard evaluation)**.** *In Setting 2.19, with its objects N, Σ, π, δ, β, κ, let X' be a finite index set, put $T = X^+ \sqcup X''^+$, with the points pt_1 of X^+ and pt_2 of X''^+, and let $V_{\mathrm{st}} = \mathrm{Hom}(\langle X'\rangle, \langle X^+\rangle^- \oplus \langle X''^+\rangle)$, a standard space with index set $T \times X'$. There are an element $k \in G_f(T \times X')$, a $T \times T$ matrix γ over $\mathbb{A}_f$ and a family $b\colon T \to \mathbb{A}_f$ such that:*

(1) the matrix of k is the Kronecker product of $\mathrm{diag}(\kappa) \cdot \gamma$ with the identity matrix of X';

(2) at every finite place w with $w \notin \Sigma$ and $\bar{w} \notin \Sigma$, every b_j has component 0 and γ has the identity as component;

(3) for every $j \in T$, $\mathsf{Nb}_{\pi,\delta}(b_j; \gamma_{\cdot j})$, where $\gamma_{\cdot j}$ is the column j of γ;

(4) $\mathsf{AdmEv}_{N,\Sigma,\beta}((f \mapsto \mathrm{at}^\flat(\omega_{V_{\mathrm{st}}}(1, k)f)); \beta^{\langle\cdot\rangle}\kappa)$ (Definition 2.21 for the spaces $\langle X^+\rangle$, $\langle X'\rangle$, $\langle X''^+\rangle$).

Proof. The element. Let $\mathbf{1}_\Sigma \in \hat{\mathcal{O}}$ be the adele equal to 1 at the places of Σ and 0 elsewhere. Then $\mathbf{1}_\Sigma \overline{\mathbf{1}_\Sigma} = 0$ and $\mathbf{1}_\Sigma \delta = \mathbf{1}_\Sigma$, as $\Sigma \cap \bar{\Sigma} = \emptyset$ and $\delta = 1$ above N. Let λ be the finite idele equal to π at the places of Σ, to $\bar{\pi}^{-1}$ at their conjugates and to 1 elsewhere; so $\lambda\bar{\lambda} = 1$. Let $\xi \in \hat{\mathcal{O}}^T$ be the vector $e_{\mathrm{pt}_1} + \overline{\epsilon_- \mathbf{1}_\Sigma}\, e_{\mathrm{pt}_2}$; then $\xi^*\xi = 1$, and

$$\gamma = 1 + (\lambda - 1)\, \xi\xi^*$$

is unitary: it multiplies ξ by λ and fixes the vectors orthogonal to ξ. For $m \in T$ put $b_m = (\lambda - 1)\pi^{-1}(\overline{\mathbf{1}_\Sigma}\,[m = \mathrm{pt}_1] + \epsilon_- \mathbf{1}_\Sigma\,[m = \mathrm{pt}_2])$, where $[m = \mathrm{pt}_1]$ is 1 if $m = \mathrm{pt}_1$ and 0 otherwise. The diagonal matrix $\mathrm{diag}(\kappa)$ is unitary, because $\kappa_b \in \{1, \delta\}$ and $\delta\bar{\delta} = 1$, and it commutes with γ, because $\gamma - 1$ is supported above N, where all

κ_b are 1. Let k be the element of $G_f(T \times X')$ acting by $\mathrm{diag}(\kappa)\gamma$ on each column $x' \in X'$. This is (1), and (2) holds because $\lambda - 1$ vanishes outside $\Sigma \cup \bar{\Sigma}$.

Neighbour vectors. $\delta b_m = b_m$ since b_m is supported above N. The entries γ_{im} with $i \neq \mathrm{pt}_1, \mathrm{pt}_2$ are those of the identity. Next $\bar{\pi}(\lambda - 1) \in \hat{\mathcal{O}}$: it is $\bar{\pi}(\pi - 1)$ at Σ, $1 - \bar{\pi}$ at $\bar{\Sigma}$ and 0 elsewhere; so $\bar{\pi}\gamma_{im} \in \hat{\mathcal{O}}$. Let $\varpi_0 = \mathbf{1}_\Sigma + (1 - \mathbf{1}_\Sigma)\pi^{-1}$, an element of $\hat{\mathcal{O}}$ since π is a unit outside Σ. A direct computation with $\mathbf{1}_\Sigma \overline{\mathbf{1}_\Sigma} = 0$ and $\overline{\epsilon_-}\epsilon_- = -1$ gives $b_m - \pi^{-1}\gamma_{\mathrm{pt}_1 m} = -\varpi_0\,[m = \mathrm{pt}_1]$ and $\overline{\epsilon_-} b_m - \pi^{-1}\gamma_{\mathrm{pt}_2 m} = -\varpi_0\,[m = \mathrm{pt}_2]$: for instance $\gamma_{\mathrm{pt}_1 m} = [m = \mathrm{pt}_1] + (\lambda - 1)([m = \mathrm{pt}_1] + \epsilon_- \mathbf{1}_\Sigma [m = \mathrm{pt}_2])$, so the coefficient of $[m = \mathrm{pt}_2]$ cancels and that of $[m = \mathrm{pt}_1]$ is $-\pi^{-1}(1 + (\lambda - 1)(1 - \overline{\mathbf{1}_\Sigma})) = -\pi^{-1}(1 + \mathbf{1}_\Sigma(\pi - 1)) = -\varpi_0$. This is (3).

The key identity. Let $\bar{\Sigma}$ be the set of the conjugates of the places of Σ and $\gamma_{X'}$ the element acting by γ on each column $x' \in X'$. We claim that there is $C_0 \in \mathbb{C}$ with

$$\omega_{V_{\mathrm{st}}}(1, \gamma_{X'})\, P^{\bar{\Sigma}} f = C_0 \sum_y \varrho_f(\overline{\mathbf{1}_\Sigma}\,\mathrm{n}(y)) P^{\bar{\Sigma}} f \qquad \text{for all } f \in \mathcal{S}(V_{\mathrm{st}}),$$

the sum over $y \in ((\mathbb{Z}/N)^\Sigma)^{X'}$, where $\mathrm{n}(y)$ is the finite vector with the entry $\epsilon_-\,\xi_i\,\overline{\tilde{y}_{x'}/N}$ at (i, x'). By Input 3(f), $P^{\bar{\Sigma}}$ is named by the indicator of the vectors integral at $\bar{\Sigma}$, the element $\gamma_{X'}$, supported at Σ and $\bar{\Sigma}$, transforms this function by $\gamma_{X'}^{-1}$ up to a constant, and translates of the indicator name the corresponding Heisenberg translates of $P^{\bar{\Sigma}}$. So the claim is an identity of functions: for every finite vector x there is an element $b(x)$ such that, for every y, the vector $\gamma_{X'}x + \mathrm{n}(y)$ is integral at $\bar{\Sigma}$ if and only if x is integral at $\bar{\Sigma}$ and $y = b(x)$. Thus the sum over y of the translated indicators has at most the one term $y = b(x)$ at $\gamma_{X'}x$, and no term when x is not integral at $\bar{\Sigma}$. At a place of $\bar{\Sigma}$ we have $\lambda = \bar{\pi}^{-1}$, $\xi = e_{\mathrm{pt}_1} + \overline{\epsilon_-} e_{\mathrm{pt}_2}$, and the column x' of $\gamma_{X'}x + \mathrm{n}(y)$ is $x_{\cdot x'} + \xi \cdot ((\bar{\pi}^{-1} - 1)x_{\mathrm{pt}_1 x'} + \epsilon_-\,\tilde{y}_{x'}/N)$. If it is integral, its coordinate at pt_1, $\bar{\pi}^{-1}x_{\mathrm{pt}_1 x'} + \epsilon_-\tilde{y}_{x'}/N$, is integral; multiplying by the uniformiser $\bar{\pi}$ and using that $\bar{\pi}/N = \pi^{-1}$ is a unit there, $x_{\mathrm{pt}_1 x'}$ is integral, and then so are all coordinates of x. Conversely, for integral x the column is integral exactly if $\bar{\pi}^{-1}x_{\mathrm{pt}_1 x'} + \epsilon_-\tilde{y}_{x'}/N$ is. The lemma of the note on the Gauss-sum operator on residues modulo N at a split level, applied after complex conjugation at Σ, provides a residue class $b_{x'}$ such that this holds if and only if $y_{x'} = b_{x'}$, the product of N and $\bar{\pi}^{-1}x_{\mathrm{pt}_1 x'}$ being integral; the family of the $b_{x'}$ is $b(x)$.

The admissible evaluation. We show (4) with the constant $C = \Delta_f(k_0)\, C_0$, where k_0 acts by $\mathrm{diag}(\kappa)$ on each column, so that $k = \gamma_{X'} k_0$. Let n be coprime to N, p a proposition and $x \in \mathrm{Tr}_n[(i, x') \mapsto \beta^{\langle i \rangle}\kappa_i]$. First, Proposition 3.4, with $c = 1$ and the set $A = \mathrm{Tr}_n[(i, x') \mapsto \beta^{\langle i \rangle}]$, shows that $\omega_{V_{\mathrm{st}}}(1, k_0)\varrho_f(x)\mathrm{vac}$ is an admissible combination of the vectors $\Delta_f(k_0)\varrho_f(z)\mathrm{vac}$, $z \in A$, away from n, with denominator D and size 1. Its hypotheses hold: k_0 multiplies the coordinate (i, x') by κ_i, and $\beta^{\langle i \rangle}\kappa_i(x + y)_{(i,x')}$ is integral away from n for $y \in \hat{\mathcal{O}}^{T \times X'}$, by the choice of x and because $\beta^{\langle i \rangle}\kappa_i \in \hat{\mathcal{O}}$; and $D/|\Delta_f(k_0)|^2 \in O^{(n)}$ by Lemma 3.2(a) with $k = 0$, because $|\Delta_f(k_0)|^2$, the index of $\hat{\mathcal{O}}^{T \times X'} \cap k_0^{-1}\hat{\mathcal{O}}^{T \times X'}$ (Input 1(c)), divides D: this lattice contains the kernel of the map $y \mapsto (\bar{y} \bmod \beta)$ to $(\hat{\mathcal{O}}/\beta\hat{\mathcal{O}})^{T \times X'}$, since a vector with coordinates $\bar{\beta}\bar{c}$, $c \in \hat{\mathcal{O}}$, is mapped by k_0 to one with coordinates $\bar{\beta}\kappa_i\bar{c} \in \hat{\mathcal{O}}$. Second, apply the linear map $\mathrm{at}^\flat \circ \omega_{V_{\mathrm{st}}}(1, \gamma_{X'})$ (Lemma 3.1(c)). Third, re-index by Lemma 3.1(f): for $z \in A$,

$$\Delta_f(k_0)\ \mathrm{at}^\flat(\omega_{V_{\mathrm{st}}}(1, \gamma_{X'})\varrho_f(z)\mathrm{vac}) = \varsigma \cdot C \cdot \mathsf{T}_{N,\Sigma}(X, X', X'')(\varrho_f(t_1)\mathrm{vac} \otimes \varrho_f(t_2)\mathrm{vac})$$

with a root of unity ς, where t_1 is ϵ_- times the conjugate transpose of the block of z with rows X^+ and t_2 is the block of z with rows X''^+; both lie in the groups of translations for $\bar\beta$ (Lemma 3.3(b)). To see this identity, note that z is integral at the places above N: they do not divide n, and β and $\bar\beta$, the weights of the two blocks, are units there. So $P^{\bar\Sigma}\varrho_f(z)\mathrm{vac} = \varrho_f(z)\mathrm{vac}$ (Input 1(f)), and the key identity gives $\omega_{V_{\mathrm{st}}}(1,\gamma_{X'})\varrho_f(z)\mathrm{vac} = C_0\sum_y \varrho_f(\overline{\mathbf{1}_\Sigma}\mathrm{n}(y))\varrho_f(z)\mathrm{vac}$. By Input 2(c) each term is a root of unity times an arrow product of two translated vacua, and the terms are those of $\mathrm{at}(\mathsf{T}_{N,\Sigma}(X,X',X'')(\varrho_f(t_1)\mathrm{vac}\otimes\varrho_f(t_2)\mathrm{vac}))$, by the definition of the translate sum (the first block of $\overline{\mathbf{1}_\Sigma}\mathrm{n}(y)$ gives the last column $-\tilde y/N$, the second block the last row $-\overline{\tilde y/N}$, with the same root of unity for all y); apply $\mathrm{at}^\flat$. □

LEAN `exists_isAdmissibleEval_std`

Proof of Theorem D. Apply Proposition 8.1 with the index set X'^+ in place of X': it gives k, γ, b with the properties (1) to (4), and the constant C of (4). Let r_1 be the finite idele $\overline{\epsilon_-}\bar\alpha/\alpha$, by which the frame of V^- differs from that of V (Definition 2.3); so the inverse finite frame of $V^-\oplus V''$ is the block diagonal matrix of $r_1^{-1}x_{V,f}^{-1}$ and $x_{V'',f}^{-1}$, and $r_1\cdot(a/\bar a) = \overline{\epsilon_-}\delta$ by the hypothesis on δ.

An integral matrix. Let M be the matrix with rows $(H\sqcup H)\sqcup T$ and columns $j\in T$ whose column j is: 0 on the first copy of H; $r_1 u b_j$ at every index of the second copy; $r_1\kappa_i\gamma_{ij}$ at $i\in X^+$; and $\kappa_i\gamma_{ij}$ at $i\in X''^+$. Let J be the inclusion matrix of the basis vectors of X'^+ into I', and

$$B = (x_{V^-\oplus V'',f}^{-1}\ \mathrm{inc}_{\mathcal{R}}\ M)\otimes(\mathsf{J}^{\mathsf{T}}x_{V',f})^{\mathsf{T}},$$

a matrix with rows $(I\sqcup I'')\times I'$ and columns $T\times X'^+$. It is integral. The second factor is: $x_{V',f} = \mathsf{L}_{\mathbf{e}_{y'}}(a,\pi,u)\,k'$ with $k'\in\mathrm{GL}_{I'}(\hat{\mathcal{O}})$, and for the even length l' the rows X'^+ of the graded lattice basis are those of the identity. The first factor is by the hypothesis (lattices), applied to r_1, $r_2 = r_1^{-1}$ and the neighbour vectors $(b_j,\gamma_{\cdot j})$ of (3): the column j of $\mathrm{inc}_{\mathcal{R}}M$ is the vector v of that hypothesis.

The zero term. By the definitions of the splittings, $B = \mathsf{i}_f k + \mathsf{k}_f c'$ for the frames of $\Xi^{\mathrm{pr}}(\mathcal{R})$ and a suitable matrix c': the columns of M split into the part $(r_1\kappa_i\gamma_{ij},\kappa_i\gamma_{ij})$, which is the frame of $\langle X^+\rangle^-\oplus\langle X''^+\rangle$ applied to $\mathrm{diag}(\kappa)\gamma$, and the part along the second copy of H, which is the isotropic frame of the splitting that removes the planes. So Proposition 5.3 gives $C_3\in\mathbb{C}$ and, for every finite vector y, a number $\varsigma(y)$, zero or a root of unity, with $\mathrm{ev}^f_{\Xi^{\mathrm{pr}}(\mathcal{R})}(\varrho_f(y)\mathrm{vac}) = \varsigma(y)\,C_3\,\omega_{V_{\mathrm{st}}}(1,k)\,\varrho_f(B^*y)\mathrm{vac}$.

The string map disappears. $B^*\,\mathbf{T}_f(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'') = 0$. Indeed $(\mathsf{J}^{\mathsf{T}}x_{V',f})^* = x_{V',f}^{-1}\mathsf{J}$, by $x_{V',f}^*J_{V'}x_{V',f} = 1$ and because $J_{V'}$ is the identity on X'^+; and $\mathbf{T}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'')\,\mathsf{J} = 0$, the string maps and their adjoints having non-zero columns only at string vectors.

Conclusion. Let n be coprime to N, p a proposition and $y\in\mathrm{Tr}_n[(i,i')\mapsto\beta^{\langle i\rangle}]$. By Definition 2.17, Input 1(a) and the two preceding paragraphs,

$$\begin{aligned}\mathrm{fev}_{\mathcal{R}}(\varrho_f(y)\mathrm{vac}) &= \varsigma'\ \mathrm{at}^\flat\ \mathrm{ev}^f_{\Xi^{\mathrm{pr}}(\mathcal{R})}(\varrho_f(\mathbf{T}_f(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'')+y)\mathrm{vac})\\ &= \varsigma'\,\varsigma(y)\,C_3\cdot\mathrm{at}^\flat(\omega_{V_{\mathrm{st}}}(1,k)\,\varrho_f(B^*y)\mathrm{vac})\end{aligned}$$

with a root of unity ς'. By Lemma 3.3(a) the vector B^*y lies in $\mathrm{Tr}_n[(j,x')\mapsto\beta^{\langle j\rangle}\kappa_j]$; its condition on the valuations is checked below. So (4) applies to B^*y, and Lemma 3.1(c) and (e) carry the scalars C_3, $\varsigma(y)$, ς': the claim holds with the constant C_3C.

The condition on the valuations. Let (i, i') be a row and (j, x') a column of B, and w a finite place with $|\beta^{\langle i\rangle}|_w \neq |\beta^{\langle j\rangle}\kappa_j|_w$; we show that the first factor of the entry of B vanishes at $\bar{w}$. That factor is $\sum_{i_1} (x^{-1}_{V^-\oplus V'',f})_{ii_1} (\mathrm{inc}_{\mathcal{R}}\, M)_{i_1 j}$. Fix i_1 and use the hypothesis (weights) for i_1 and j. If $\mathrm{inc}_{\mathcal{R}}(i_1, j) = 0$: the place $\bar{w}$ does not lie above N, since above N all κ are 1 and β is a unit, so that the two absolute values would both be 1; hence, by (2), at $\bar{w}$ the b's vanish and γ is the identity, the column j of M has at $\bar{w}$ only the entry at the index j, and $(\mathrm{inc}_{\mathcal{R}}\, M)_{i_1 j}$ is a multiple of $\mathrm{inc}_{\mathcal{R}}(i_1, j) = 0$ there. Otherwise $|\beta^{\langle i_1\rangle}|_w = |\beta^{\langle j\rangle}\kappa_j|_w \neq |\beta^{\langle i\rangle}|_w$, so i_1 and i lie in different ones of the two sets I, I'', and $(x^{-1}_{V^-\oplus V'',f})_{ii_1} = 0$ because this matrix is block diagonal. □

LEAN `isAdmissibleEval_finEval`

9 Where the results are used

In the unit. The note on the seesaw identity uses: Theorem A and Lemma 3.1 wherever a denominator or a size is tracked (the unfolding to an admissible combination, the combination of reduced vacua, the passage to a good datum); Lemma 3.2(a) for the multiplicities of the finite cuts, which divide powers of the conductor of the twist; Theorem C, with the middle pairs and the last pair of Definition 2.18 for the gradings of the spaces of the chain of lifts, to identify the function left after $2i + 2$ unfoldings with a matrix coefficient of $i + 1$ pairs of definite lifts; Theorem B(ii) for the invariance of the evaluated data under the levels; Theorem D, Lemma 4.3 and Proposition 3.4, with Lemma 3.2(b) to (d), to write the evaluated data through reduced vacua; and Proposition 5.2 in the step that bounds how far the lines of a lattice move under one lift.

In other units. Admissible coefficients enter the definition of a good datum in the unit of the columns, and admissible combinations are produced in the unit of the CM curve (named data as combinations of translated vacua) and used in the units of the exchange identity and of the rows. Propositions 4.1 and 4.2 are used in the unit that constructs the spaces of the chain of lifts and in the unit of the filling: the first shows that the lattice spanned by the graded lattice basis is self-dual, the second provides the real part of the frame.

10 Notes on the formal text

Arguments. The lists of arguments used by the checks of this note are read from the text of the artifact, not printed by Lean. They contain entries that Lean does not take, as the reader's dossier records: an index type listed for $O^{(n)}$; an index type listed for admissible evaluations; and a first copy of the field instances for Proposition 8.1 and for Theorem D. The two index sets X'', H of an arrow pair are listed twice, as implicit and as explicit arguments, because a prefix makes them explicit for that declaration. For admissible evaluations the lists also carry a finite index type named like the proposition of Definition 2.21, with its finiteness: the definition binds that name as the proposition p and its translate sum has the three index sets X, X', X'' only, so these two entries are inferred from the text, as the second reader of the dossier notes; a signature printed by Lean would settle them. In the other direction, the text reading of Theorem C(ii) misses the field E, the index sets X, X', X_0 and their instances, which the formal statement names after a local

definition; they stand in the statement above. In Theorem A(i) the two hypotheses on d'' and C have default proofs by simplification, so that the formal text can omit them at a use.

Differences from the statements above. (1) Coprimality of a prime ℓ and n is the formal hypothesis in Theorem A(ii) and Definition 2.7; for $n = 0$ no prime is coprime to n, so $O^{(0)} = \mathbb{C}$. (2) The automorphisms σ are ring automorphisms of $\mathbb{C}$. (3) The ring homomorphism $\jmath$ is an instance argument in Theorem A(ii) and an ordinary one in Lemma 3.2(c), (d). (4) The finite zero term and the left inverse $\mathrm{at}^\flat$ depend on choices made once by the axiom of choice (an adapted element; a left inverse of an injective linear map). (5) The denominator D of Definition 2.21 is a cardinality that is 0 when infinite. (6) In Definition 2.16 the subtraction is that of natural numbers. (7) In Theorem C(ii) the hypothesis is the library's predicate on families of lifts, stated here as Input 5; the characters enter through the twist $\mu \mapsto \mu\upsilon^{\lfloor |X|/2 \rfloor}$. (8) Proposition 4.2 takes a ring homomorphism ϕ that only transports an integer matrix, and Proposition 4.1 a homomorphism $f\colon S \to R$ of the same kind. (9) The formal statements of Lemma 3.1(a) and of Theorem A(iii) are for a finite subset given as such, and for the iterated tensor product of the library, in which the factor of index $m - 1$ stands first. (10) In Lemma 3.1(h) the scalar is Mathlib's normalising unit, with its value 1 at zero; its description is recalled, Mathlib not being part of the text read. The scalar must not be simplified to d/C: nothing is assumed non-zero, and for $a = 0$ the vector of the conclusion is zero. (11) In Definition 2.9 and in Theorem D the two blocks of a vector carry the weights β and $\bar{\beta}$; they are never replaced by one common weight.

What the formal proofs do differently. The unitary matrix γ of Proposition 8.1 is given entry by entry in the formal text, and its unitarity and the properties of neighbour vectors are found by automation from a list of identities; the description $\gamma = 1 + (\lambda - 1)\xi\xi^*$ and the computations with it are ours. The comparison of the scalars in Theorem B(i) is, formally, a linear-arithmetic certificate; the count with the weights is ours. The identity of functions behind the key identity of Proposition 8.1, and the condition on the valuations in Theorem D, are long simplification chains in the formal text, which we read as the identities they establish and derived again by hand. Lemma 3.2(c), (d) are not expanded. Which hypotheses the formal proofs leave unused was not determined: nothing was compiled for this note.

The dossier and its second reading. The reader's dossier describes Input 3(e) without the factor $\upsilon(\det h)^{|H|}$. The formal statement has it, through a twist of one of the two characters, and the scalars of Theorem B(i) agree only with it. A second reader compared the dossier of the unit with the Lean text after this note was drafted. Her corrections that concern this note are followed here: the zero case of Lemma 3.1(h), where the dossier had simplified the scalar; the two weights of the blocks; the index types and the proposition in Definition 2.21; and, in Proposition 8.1, that the comparison of indicators leaves at most one term.

How this note was written. From the structured proofs of the reader's dossier for the eight files of this note, after its program check passed. We read these eight files of the Lean text completely, the statements argument by argument, and line by line the proofs of Theorem B(i), Proposition 8.1 and Theorem D, which the reader had marked as read from the names of the lemmas only; the two statements with a local definition (Theorem C) were read in full. Of the background library we read the statements and comments of the declarations quoted as Inputs 1 to 7, and none of their proofs. No Lean was run. The program check of the unit's dossier covered 503 leaf steps of 83 proofs.

Revision. After an independent referee's report the note was revised. Step 4 of the proof of Theorem C(i) now proves that no Heisenberg factor arises, from the isotropy of the stacked string map, which is where the condition $\mathfrak{c}(\mathcal{Y}') = \mathfrak{c}(\mathcal{Y})$ of an arrow pair enters, as in the formal proof; Inputs 2(h), 4(b) and 4(d) were added or restated from the Lean source; the constant term is written as a mean of values of the theta functional; and the names of the library's objects (string map, translate sum, finite Heisenberg operators) are those of the other notes of the unit.

Appendix A. Concordance with the Lean artifact

The first 57 rows are the declarations of the unit treated here; the rows whose place is an Input are declarations of the background library, quoted and not read.

Legend. Formal names of objects and our letters: *Space* with its matrix and point: a hermitian space V with J_V and the frame x_V; the data space, the Heisenberg and finite Heisenberg operators, the vacuum, the finite part: $\mathcal{S}(V)$, ϱ_V, $\varrho_{f,V}$, vac_V, $\mathcal{W}_f(V)$; *integrated*: $v \otimes f$; *Splitting* with its fields k, l, i: Ξ with k_Ξ, l_Ξ, i_Ξ; *zeroTerm*: ev_Ξ; *Grading* with *indexEquiv*, c, *gradeOf*, *inclX*, *stringMap*: $\mathcal{Y}$ with $\mathbf{e}_\mathcal{Y}$, $\mathfrak{c}(\mathcal{Y})$, $\mathrm{gr}_\mathcal{Y}$, $\imath_\mathcal{Y}$, $T_{\mathcal{Y},\mathcal{Y}'}$; *arrowProduct*, *arrowTensor*, *tripleWeil*, *liftWeilFin*: $\boxtimes$, at, $\omega^{\mathrm{tr}}_{\mu,\mu'}$, $\omega^{\mathrm{pr},f}_{\mu}$; the fields *zeroPart*, *embX*, *gradeOne* of an arrow pair: $\mathcal{Z}_\mathcal{R}$, $\mathrm{emb}_\mathcal{R}$, $\gamma_\mathcal{R}$; *normNegOne*: $\epsilon_{_}$; *translateSum*: $\mathsf{T}_{N,\Sigma}(X, X', X'')$.

Notation

E, $\mathbb{A}$, $\mathbb{A}_f$, $\hat{\mathcal{O}}$ a CM field with a CM type; its adeles, finite adeles, integral finite adeles

w, $\bar{w}$, $|\cdot|_w$, O_w a finite place, its conjugate, its absolute value, its ring of integers

$\mathbf{j}$, α, v, $\epsilon_{_}$ Weil data: an element of E, an idele, the splitting character; a unit of $\hat{\mathcal{O}}$ of norm -1

ℓ, $\jmath$, $O_\jmath$, σ a prime; a ring homomorphism $\mathbb{C} \to \mathbb{C}_\ell$; its ring of integral complex numbers; an automorphism of $\mathbb{C}$

$O^{(n)}$ complex numbers integral away from n

$\mathcal{X}$, $\mathcal{X}'$, $\mathcal{X}_j$, A, A', A_j index sets of families of vectors and subsets of them

Z, Z', W, F_i, M complex vector spaces; an $O_\jmath$-submodule (also: a matrix)

v, v', v_i, z, z', f_i families of vectors and vectors (also: v a real datum, f a datum or a map)

n, d, d', d'', m, k natural numbers: the modulus of integrality, denominators, a number of factors, an exponent (also: k a group element, d a family of adeles)

p, B, B', C, C_0, C_1, C_2, C_3, D a proposition; real bounds; complex constants; a denominator

r, r_x, c, ρ, ς coefficient functions; a root of unity or zero (also: r a group element, c an adele or matrix)

$r \in \mathrm{Co}(A; n, d; p, B)$ admissible coefficients

$z \in \mathrm{Adm}(v, A; n, d; p, B)$ admissible combination

nu, L, b the inverse or 1; a linear map; a bilinear map (also: b an index or a vector)

I, I', I'', I_0, I_1, I_2, X, X', X'', X_0, H, T, U finite index sets; a set of parameters o

X^+, pt, pt_1, pt_2 an index set with one more point; the points

V, V', V'', V_0, V_{st}, J_V, x_V, $x_{V,f}$ hermitian spaces; matrix, frame, finite frame

$G(V)$, $G_f(I)$, $\Gamma(V)$, $[G(V)]$ the adelic unitary group, its finite part, rational points, quotient

$\langle X\rangle$, $\mathrm{Hom}(V,V')$, $V^{-}\oplus V''$, $\mathbb{H}^{H}\oplus V$ standard space; homomorphisms; first form negated; with hyperbolic planes

$\mathcal{S}(V)$, $\mathcal{F}(V)$, $\mathcal{W}_{f}(V)$, vac_{V}, v_{Q}, Q data, real data, finite part, vacuum, polynomial vectors, polynomials

ϱ_{V}, $\varrho_{f,V}$, ω_{V}, θ_{V}, Δ_{f}, ψ_{0}, ψ_{f}, P^{S} Heisenberg and finite Heisenberg operators, Weil representation, theta functional, finite multiplier, additive characters, a projection

y, y_{f}, $y^{\dagger}$, x, u, g, g', h, a vectors and matrices, finite coordinates, adjoint; group elements (also: a an idele, u a unitary adele)

μ, μ', μ_{V}, μ_{o} characters of $\mathrm{U}(1)(\mathbb{A})$; twisted by a power of v

$\omega_{\mu}^{\mathrm{pr}}$, $\omega_{\mu}^{\mathrm{pr},f}$, $\omega_{\mu,\mu'}^{\mathrm{tr}}$, $\omega_{a,b}$ twisted pair action, its finite part, the triple action; the pair action with two characters of the note on the Gauss-sum operator

$\boxtimes$, at, $\mathrm{at}^{\flat}$ arrow product; the induced map on finite parts; a left inverse

Ξ, k_{Ξ}, l_{Ξ}, i_{Ξ}, ev_{Ξ}, ev_{Ξ}^{f} a splitting, its frames, its zero term, its finite zero term

Λ, ϵ, v_{vac}, v_{Ξ} objects of Input 3: a map of real data, a function, the real vacuum and its translate

$\mathcal{Y}$, $\mathcal{Y}'$, $\mathcal{Y}''$, $\mathrm{e}_{\mathcal{Y}}$, l, l', l'', N, $\mathfrak{c}(\mathcal{Y})$ gradings: bijection, string lengths, norm, constant

$\mathrm{gr}_{\mathcal{Y}}$, $\imath_{\mathcal{Y}}$, $\imath_{\mathcal{Y}}^{f}$, $B(\mathcal{Y})$, $[B(\mathcal{Y})]$, $T_{\mathcal{Y},\mathcal{Y}'}$, $\mathrm{sh}_{\mathcal{Y}}$ grade, inclusion of the definite part, Bessel group and quotient, string map, shift

$\mathrm{ct}_{\mathcal{Y},\mathcal{Y}'}^{\mu}(f)$, P, $\mathrm{Gr}_{\mathrm{e}}(N)$, $\mathrm{bi}(x,y)$, $\psi_{\mathbb{A}}$ constant term at the string map; a generic function; the Gram matrix of a string; the Heisenberg bicharacter; the standard additive character of the adeles

$\mathrm{Tr}_{n}[d]$, $\mathrm{Tr}_{n}^{I}[d]$, $\beta^{\langle j\rangle}$ groups of translations; β or its conjugate

$\mathsf{SqF}_{\Sigma}(N;\pi)$ the split squarefree condition

$\mathsf{L}_{\mathrm{e}}(a,\pi,u)$, $\mathsf{Lat}(\mathcal{Y};a,\pi,u)$ graded lattice basis; the lattice condition

R, R_{0}, S, ϕ, ε, η_{b}, e_{i}, g_{i} rings and a homomorphism; signs; basis vectors and columns

wt, $\mathrm{GZ}(V,V'';\mathrm{wt})$, $\mathcal{Z}$, $\mathrm{ind}_{\mathcal{Z}}$, $\mathrm{inc}_{\mathcal{Z}}$, $\Xi(\mathcal{Z})$, $\mathrm{Hom}(\mathcal{Y}',\mathcal{Z})^{0}$ weights; grade-zero parts with injection and matrix; their splitting; the part of a space of homomorphisms

$\mathbf{T}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'')$, $\mathbf{T}_{f}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'')$ the stacked string map and its finite coordinates

$\mathrm{Arr}_{X'',H}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'')$, $\mathcal{R}$, $\mathcal{Z}_{\mathcal{R}}$, $\mathrm{inc}_{\mathcal{R}}$, $\mathrm{ind}_{\mathcal{R}}$, $\mathrm{emb}_{\mathcal{R}}$, $\gamma_{\mathcal{R}}$ arrow pairs and their components

$\mathcal{Z}^{\mathrm{Hom}}(\mathcal{R})$, $\Xi^{\mathrm{pr}}(\mathcal{R})$, $\mathrm{fev}_{\mathcal{R}}$ grade-zero part, splitting and finite evaluation of an arrow pair

$\mathcal{R}_{\mathrm{mid}}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'')$, $\mathcal{R}_{\mathrm{last}}(\mathcal{Y},\mathcal{Y}',\mathcal{Y}'';\pi_{0})$, π_{0} the middle pair and the last pair

$\varkappa$, e, e', e'', $\mathcal{A}(X;\varkappa,e)$, φ, t, t', t'', coef_{t} weight and determinant exponents; algebraic forms; functionals; coefficients

$\mathcal{L}_{o}$, $\mathcal{L}_{o}'$, $\mathcal{L}_{o}''$, Φ, Φ', Ψ, $\mathcal{I}$ theta lifts and their composite; finite data; a function that names an operator; an integral

Σ, $\bar{\Sigma}$, π, δ, β, κ a split level and its conjugate; the objects of Setting 2.19

$\mathsf{Nb}_{\pi,\delta}(c;x)$ neighbour vector

$\mathsf{AdmEv}_{N,\Sigma,\beta}(L;d)$, $\mathsf{T}_{N,\Sigma}(X,X',X'')$, $\tilde{y}$ admissible evaluation; the translate sum; least non-negative representatives

γ, $\gamma_{X'}$, λ, ξ, $\mathbf{1}_{\Sigma}$, ϖ_{0}, $\mathrm{n}(y)$, k_{0}, B, J, c objects of the proofs of Proposition 8.1 and Theorem D

z_{0}, F, M, m_{+}, j, i, q, G, K, O, Y, s further letters of the proofs: constants, functions, counts and indices; G, O, Y, K, s, q occur only inside the symbols above

A, A', B topological abelian groups in Input 7

READBACK NOTE 23

Chains of definite theta lifts and the Gauss-sum operator at the level prime

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. At the level prime N, which splits completely in the CM field, a theta lift between definite unitary groups is governed by functions of residue matrices modulo N. This note isolates the formal law that one lift obeys there, defines the *Gauss-sum operator* F, a finite Fourier transform in the last row followed by $\mathrm{diag}(1,\dots,1,N^{-1})$, and proves that F slides through a chain of lifts (Theorem A). Theorem B rewrites the sums of translates with denominator N that the seesaw identity produces as data of exactly this kind. Theorem C turns a jointly invariant combination of chains into a plain sum over classes, and Theorem D bounds, at an embedding above N, what powers of F cost in integrality.

What this note is. The artifact grh-compact is a body of Lean code whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. Its authors report that all files compile and that Lean's kernel accepts these theorems from its standard axioms; nothing was compiled for this note, and no mathematician has read the argument through. The headline is therefore a *claim*, and this note does not say that it is proved: it says what one part of the formal text asserts and how it argues. The part is 78 of the 312 declarations of the unit *Seesaw*: its files on names at a split level and on the characters of the lifts, which serve Theorem A of the write-up (short forms). The other declarations of the unit are treated in further notes of the unit (the index sets and characters of the data; two consecutive lifts; the seesaw identity). Every statement below was compared, argument by argument, with its Lean text, and every proof is written out, except where an *Input* from another unit or a quoted result of the background library is named with its owner. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 78 declarations.

1 The statements

The theorems are stated in the settings that follow. The notions they use are defined in §2; the place of each definition is given in the setting.

Setting 1.1 (a split level)**.** E is a CM field with a CM type and Weil data, N is a prime number, and Σ is a finite set of finite places of E that is a split level for N (Definition 2.1): Σ is disjoint from its complex conjugate, each of its places has norm N and uniformiser N, and the places of E dividing N are those of Σ and their conjugates. We write $E_\Sigma = \prod_{w\in\Sigma} E_w$, O_Σ for its ring of integral elements and $\mathrm{red}\colon O_\Sigma \to (\mathbb{Z}/N)^\Sigma$ for the reduction modulo N (Definition 2.2). For a finite index set I we put $I^+ = I \sqcup \{*\}$, with $*$ the *last index*, and $\mathbf{e}$ is the last basis vector of $((\mathbb{Z}/N)^\Sigma)^{I^+}$. Functions f of matrices over $(\mathbb{Z}/N)^\Sigma$ give functions $f^\natural$ of matrices over E_Σ; among them are the indicators $\mathbf{b}_y$ of a last column and the characters $\mathbf{c}_y$ of a last

row (Definition 2.4). For a complex representation ρ of $\mathrm{GL}_{I^+}(E_\Sigma)$, $\mathrm{Ram}(\rho)$ is its set of ramified vectors (Definition 2.3) and $\mathsf{F}(\rho)$ its Gauss-sum operator (Definition 2.6); u_0 is the matrix $\mathrm{diag}(1,\dots,1,N^{-1})$ at every place of Σ (Definition 2.3).

Theorem A (the Gauss-sum operator slides through a chain of lift laws)**.** In Setting 1.1, let $I_0, I_1, I_2, \dots$ be finite index sets, let ρ_j be a complex representation of $\mathrm{GL}_{I_j^+}(E_\Sigma)$ for each $j \geq 0$, and let L_j and $\varkappa_j \in \mathbb{C}$ be such that, for every j, L_j is a lift law from ρ_j to ρ_{j+1} with constant $\varkappa_j$ (Definition 2.7). Let $\varphi \in \mathrm{Ram}(\rho_0)$, let $d_0, d_1, \dots$ be complex numbers and let $p \geq 0$. For $i \geq 0$ put

$$A_i \;=\; d_i \cdot \rho_{2i+2}(u_0) \circ \sum_y L_{2i+1}[\mathbf{c}_y] \circ L_{2i}[\mathbf{b}_y] \;:\; \rho_{2i} \to \rho_{2i+2},$$

the sum over all $y \in ((\mathbb{Z}/N)^\Sigma)^{I^+_{2i+1}}$, and let o_i be the number of those y that are non-zero at every place: for every $w \in \Sigma$ some entry of y has non-zero component at w. Then

$$A_{p-1} \circ \dots \circ A_0\,(\varphi) \;=\; \Big(\prod_{i<p} d_i\, o_i \prod_{l<2i+2} \varkappa_l\Big) \cdot L_{2p-1}[\mathbf{b}_{\mathbf{e}}] \circ \dots \circ L_0[\mathbf{b}_{\mathbf{e}}](\mathsf{F}(\rho_0)^{\,p}\varphi).$$

Theorem B (translates with denominator N are named data)**.** In Setting 1.1, let Σ' be a second finite set of finite places of E that is a split level for N, let I, I', I'' be finite index sets, and put $\mathcal{H} = \mathrm{Hom}(X_{I^+}, X_{I'})$ and $\mathcal{H}' = \mathrm{Hom}(X_{I'}, X_{I''^+})$, where X_J is the standard definite hermitian space on an index set J, and let $v \in \mathcal{W}_f(\mathcal{H})$ and $v' \in \mathcal{W}_f(\mathcal{H}')$ be elements of the finite parts of their Weil representations (Definition 2.12). Then

$$\begin{aligned}&\mathsf{T}_{N,\Sigma'}(I, I', I'')(\mathrm{pr}^{\Sigma'}_{\mathcal{H}}\, v \otimes \mathrm{pr}^{\Sigma'}_{\mathcal{H}'}\, v') \\ &\quad= \sum_z \mathrm{nm}_\Sigma(S \mapsto \mathbf{b}_z(S \cdot \mathrm{dg}_I(\Sigma')))\, v \otimes \mathrm{nm}_\Sigma(S' \mapsto \mathbf{c}_z(\mathrm{dg}_{I''}(\Sigma \smallsetminus \Sigma') \cdot S'))\, v',\end{aligned}$$

the sum over all $z \in ((\mathbb{Z}/N)^\Sigma)^{I'}$. Here $\mathsf{T}_{N,\Sigma'}(I, I', I'')$ is the sum of the pairs of translations by vectors with denominator N at Σ', $\mathrm{pr}^{\Sigma'}_{\mathcal{H}}$ the projection of $\mathcal{W}_f(\mathcal{H})$ to the vectors that are vacua above $\Sigma' \cup \overline{\Sigma'}$, $\mathrm{nm}_\Sigma(F)$ the operator named at Σ by a function F of matrices over E_Σ (Definition 2.12), and $\mathrm{dg}_I(\Sigma')$ the diagonal matrix with last entry N at the places of $\Sigma \cap \Sigma'$ (Definition 2.3); the matrices $\mathrm{dg}_I(\Sigma')$ and $\mathrm{dg}_{I''}(\Sigma \smallsetminus \Sigma')$ are formed for the split level Σ.

Setting 1.2 (a chain of kernels)**.** E is a CM field with a CM type. For $j \geq 0$: I_j is a finite index set and $G_f(I_j)$ the group of finite adelic points of the unitary group of the standard definite hermitian space on I_j; κ is a weight and e_j a last entry, so that $\mathcal{A}(I_j; e_j)$ is the space of algebraic modular forms of weight (κ, e_j) on $G_f(I_j)$, with values in the space $W_\kappa(I_j)$ of the weight; K_j is a level (a compact open subgroup of the stabiliser $K_0(I_j)$ of the standard lattice), $\mathcal{S}_j$ is a complex vector space, and $\mathcal{K}_j$ is a theta kernel from I_j to I_{j+1} with weights (κ, e_j), (κ, e_{j+1}), level K_j and data in $\mathcal{S}_j$ (Definition 2.8), with its representation ω_j of $G_f(I_j) \times G_f(I_{j+1})$ on $\mathcal{S}_j$ and its jet matrix $\mathcal{J}_j$. The chain $\mathrm{ch}(\mathcal{K}; \Phi)_j \colon \mathcal{A}(I_0; e_0) \to \mathcal{A}(I_j; e_j)$ of the first j lifts with data $\Phi = (\Phi_j)_j$, $\Phi_j \in \mathcal{S}_j$, is defined in Definition 2.9.

Theorem C (a jointly invariant combination of chains is a sum over classes)**.** In Setting 1.2, let M be a complex vector space, $\mathcal{X}$ a set, $m \geq 0$ a natural number, $\mathcal{X}_0 \subseteq \mathcal{X}$ a finite subset, $L_x \colon W_\kappa(I_m) \to M$ a linear map and $\Phi_x = (\Phi_{x,j})_j$ a family of data, for each $x \in \mathcal{X}$. Let $\varphi \in \mathcal{A}(I_0; e_0)$, let $P_j(g,u)$ be a property of a point $g \in G_f(I_j)$ and a vector $u \in W_\kappa(I_j)$ for each j, let $h \in G_f(I_m)$ and let $A \subseteq M$. Assume:

(a) the family $(L_x, \Phi_x)_{x \in \mathcal{X}_0}$ is jointly invariant of length m for $\mathcal{X}$ (Definition 2.10);

(b) for every $j < m$ and every $g \in G_f(I_j)$, the group of rational points in gK_jg^{-1} is trivial;

(c) φ is fixed by K_0 under right translation;

(d) for all $x \in \mathcal{X}_0$, $j < m$, points $g \in G_f(I_j)$, $g' \in G_f(I_{j+1})$ and vectors u: $P_j(g,u)$ implies $P_{j+1}(g', \mathcal{J}_j(\omega_j(g,g')\Phi_{x,j})\, u)$;

(e) $P_0(g, \varphi(g))$ for every $g \in G_f(I_0)$;

(f) for every linear map $\beta \colon \mathcal{S}_{m-1} \otimes \cdots \otimes \mathcal{S}_0 \to W_\kappa(I_m)$: if $P_m(h, \beta(\Phi_{x,m-1} \otimes \cdots \otimes \Phi_{x,0}))$ for all $x \in \mathcal{X}_0$, then $\sum_{x \in \mathcal{X}_0} L_x(\beta(\Phi_{x,m-1} \otimes \cdots \otimes \Phi_{x,0})) \in A$.

Then $\sum_{x \in \mathcal{X}_0} L_x(\mathrm{ch}(\mathcal{K}; \Phi_x)_m(\varphi)(h))$ is a sum of $\prod_{j<m} \mathrm{cl}(K_j)$ elements of A, where $\mathrm{cl}(K_j)$ is the number of double cosets of $G_f(I_j)$ modulo the rational points on the left and K_j on the right.

Setting 1.3 (the data at the level prime)**.** $P = (N_0, d)$ are parameters and D is admissible data for P (Chapter III), with components: the scales x, x_1, b, the exponent μ, the number of lifts m, the rank r, the thick set, the primes g_0, g_1 and the integer π_g. Attached to D are the CM field $E(D)$ with its number $f(D)$ of infinite places, the level prime $N(D)$ and the integer $\pi_N(D)$ of $E(D)$ with $\pi_N(D)\overline{\pi_N(D)} = N(D)$, the set $\Pi(D)$ of places dividing $\pi_N(D)$, the number $\varrho(D)$ with $m = 2\varrho(D) + 2$, the index sets $\underline{X}_j(D) = \underline{X}_j^\circ(D) \sqcup \{*\}$ of the standard definite spaces $X_j(D)$, the spaces $\mathrm{St}_j(D)$ of algebraic forms on $X_j(D)$ (stage j), the level $K_j^{\mathrm{col}}(D)$ of stage j, the space $\mathrm{Col}(D) \subseteq \mathrm{St}_0(D)$ of columns and its subspace $\mathrm{Col}^{\mathrm{ram}}(D)$ of ramified columns (Definition 2.13, which recalls them from the notes on the data and on the columns). Moreover $\jmath \colon \mathbb{C} \to \mathbb{C}_{N(D)}$ is a ring homomorphism, $O_\jmath$ is the ring of the complex numbers z with $|\jmath(z)| \leq 1$, $\Sigma_\jmath(D)$ is the set of non-induced places above $N(D)$, a split level for $N(D)$, $\Delta_j(D)$ is the diagonal point of stage j and $\rho_{D,j}$ the representation of $\mathrm{GL}_{\underline{X}_j(D)}(E_{\Sigma_\jmath(D)})$ on $\mathrm{St}_j(D)$ (Definition 2.15); $\mathrm{Int}_\jmath(\mathcal{V}; \mathsf{d})$ is the $O_\jmath$-module of the forms of a space $\mathcal{V}$ that are $\jmath$-integral at a point d (Definition 2.14).

Theorem D (powers of the Gauss-sum operator on integral columns)**.** In Setting 1.3, with the structure of a split level for $N(D)$ on $\Sigma_j(D)$ given by Lemma 7.1, there is a natural number e with

$$e \;\le\; 4\,m\cdot f(D)\cdot b\cdot \dim_{\mathbb{C}}\mathrm{Col}(D)$$

such that for every $n\ge 0$ and all $\Phi_1,\dots,\Phi_n\in \mathrm{Int}_j(\mathrm{Col}(D);1)$ there is an $n\times n$ matrix u over O_j whose determinant divides $N(D)^{\,e}$ in O_j and for which every $\psi_i=\sum_k u_{ik}\Phi_k$ satisfies

$$\mathsf{F}(\rho_{D,0})^{\,\varrho(D)+1}\,\psi_i \;\in\; \mathrm{Int}_j(\mathrm{Col}(D);\Delta_0(D)).$$

2 The setting

Conventions. E is a CM field with a fixed CM type; $x\mapsto\overline{x}$ is its complex conjugation. $\mathbb{A}_f$ is the ring of finite adeles of E and $\hat{\mathcal{O}}$ its ring of integers. Finite places of E are written w, v; $\overline{w}$ is the conjugate place, E_w the completion with ring of integers O_w, residue field $\mathbb{F}_w$ and norm $\mathrm{N}w=\#\mathbb{F}_w$. Whenever the additive character ψ_0 or a Weil representation occurs, E carries Weil data: an element $\mathbf{j}$ of E with $\overline{\mathbf{j}}=-\mathbf{j}$, a finite idele α and a splitting character υ; then $\psi_0(t)=\psi_f(\mathbf{j}\alpha\overline{\alpha}\,t)$, with ψ_f the standard additive character of the finite adeles, is an additive character of $\mathbb{A}_f$ that is trivial on $\hat{\mathcal{O}}$ and whose values are roots of unity. An infinite place τ of E is identified with the embedding $E\to\mathbb{C}$ of the CM type above it. N is a prime number; Σ and Σ' are finite sets of finite places of E. That such a set is a split level is a hypothesis; it is stated in each statement or in the setting it cites, and Lean carries it as an instance argument. Index sets I, I', I'', I_j, J are finite index sets, and $I^+=I\sqcup\{*\}$. R is a commutative ring. Representations are on complex vector spaces. For a finite index set I, X_I is the standard definite hermitian space E^I with the form $\sum_i\overline{x_i}y_i$, $G_f(I)$ the group of finite adelic points of its unitary group, and $K_0(I)=G_f(I)\cap\mathrm{GL}_I(\hat{\mathcal{O}})$. In Setting 1.2: the $\mathcal{S}_j$ are the data spaces, complex vector spaces; the K_j are levels; κ is the weight and the e_j are the last entries; Φ denotes data; M is a complex vector space (so also a rational one, which the class integral needs). In Setting 1.3: $P=(N_0,d)$ are parameters, D is admissible data, ℓ is a prime number and $\jmath\colon\mathbb{C}\to\mathbb{C}_\ell$ a ring homomorphism, with $\ell=N(D)$ where the statement says so.

Split levels.

Definition 2.1 (split level; residues over N)**.** Let Σ be a finite set of finite places of E and N a natural number. We say that Σ is a split level for N if: (a) $\overline{w}\notin\Sigma$ for every $w\in\Sigma$; (b) $\mathrm{N}w=N$ for every $w\in\Sigma$; (c) N is a uniformiser of E_w for every $w\in\Sigma$; (d) a finite place w of E divides N if and only if $w\in\Sigma$ or $\overline{w}\in\Sigma$. For any Σ and N put $E_\Sigma=\prod_{w\in\Sigma}E_w$ and let $O_\Sigma=\prod_{w\in\Sigma}O_w$ be its ring of integral elements. For $N>0$ and $y\in(\mathbb{Z}/N)^\Sigma$ let $\tilde{y}_w\in\{0,\dots,N-1\}$ be the least non-negative representative of

y_w; then $[y/N] \in \mathbb{A}_f$ is the finite adele with component $\tilde{y}_w/N$ at each $w \in \Sigma$ and 0 at the other places, and, for E with Weil data,

$$\psi_N(y) \;=\; \psi_0(-[y/N]).$$

LEAN `IsSplitLevel` · `residueOverN` · `residueOverN_apply` (the formula for the components, a restatement of the definition) · `IsSplitLevel.psiN`

Definition 2.2 (reduction modulo N)**.** Let Σ is a split level for N, with N prime; we say for short that Σ is a split level. For $w \in \Sigma$ the residue field $\mathbb{F}_w$ has N elements by (b), so there is exactly one ring isomorphism $\mathbb{F}_w \to \mathbb{Z}/N$. The *reduction* $\mathrm{red}\colon O_\Sigma \to (\mathbb{Z}/N)^\Sigma$ is the ring homomorphism whose component at w is the residue map $O_w \to \mathbb{F}_w$ followed by this isomorphism. For a finite index set I we regard $\mathrm{GL}_I(O_\Sigma)$ as a subgroup of $\mathrm{GL}_I(E_\Sigma)$, write again $\mathrm{red}\colon \mathrm{GL}_I(O_\Sigma) \to \mathrm{GL}_I((\mathbb{Z}/N)^\Sigma)$ for the entrywise reduction, and fix a map $\mathrm{sec}\colon \mathrm{GL}_I((\mathbb{Z}/N)^\Sigma) \to \mathrm{GL}_I(O_\Sigma)$ with $\mathrm{red} \circ \mathrm{sec} = \mathrm{id}$. It exists: an entry $y \in (\mathbb{Z}/N)^\Sigma$ lifts to $(\tilde{y}_w)_w \in O_\Sigma$, and a matrix over O_Σ whose reduction is invertible is invertible, because an element of O_Σ with invertible reduction is a unit. The *last basis vector* $\mathbf{e} \in ((\mathbb{Z}/N)^\Sigma)^{I^+}$ is the function $(i, w) \mapsto 1$ if $i = *$ and $(i, w) \mapsto 0$ otherwise, for $i \in I^+$ and $w \in \Sigma$.

Definition 2.3 (diagonal elements, the mirabolic group, ramified vectors)**.** Let Σ be a split level for the prime N, I a finite index set and Σ' a finite set of finite places. Then $\mathrm{dg}_I(\Sigma') \in \mathrm{GL}_{I^+}(E_\Sigma)$ is the diagonal matrix with entries 1 at the indices of I and, at the last index, the element of E_Σ whose component is N at the $w \in \Sigma \cap \Sigma'$ and 1 at the other $w \in \Sigma$. We put

$$u_0 \;=\; \mathrm{dg}_I(\Sigma)^{-1},$$

the matrix $\mathrm{diag}(1, \dots, 1, N^{-1})$ at every place of Σ (we write u_0 in every rank). The *mirabolic group* $\mathrm{Mir}(I) \subseteq \mathrm{GL}_{I^+}(E_\Sigma)$ consists of the $k \in \mathrm{GL}_{I^+}(O_\Sigma)$ with $\mathrm{red}(k)\,\mathbf{e} = \mathbf{e}$, that is, whose last column is congruent to $\mathbf{e}$ modulo N. For a complex representation ρ of $\mathrm{GL}_{I^+}(E_\Sigma)$, a vector φ of ρ is *ramified* if for every $w \in \Sigma$ there is a unit x of O_Σ with $\mathrm{red}(x)_v = 1$ for all $v \in \Sigma$, $v \neq w$, such that φ lies in the image of $1 - \rho(x \cdot 1)$, where $x \cdot 1$ is the scalar matrix; $\mathrm{Ram}(\rho)$ is the set of ramified vectors.

LEAN `IsSplitLevel.diagN` · `IsSplitLevel.diagNInv` · `IsSplitLevel.mirabolic` · `IsSplitLevel.ramified`

Definition 2.4 (functions of residue matrices)**.** Let Σ be a split level for the prime N and I, I' finite index sets. For a complex function f of $I' \times I$ matrices over $(\mathbb{Z}/N)^\Sigma$, $f^\natural$ is the function of $I' \times I$ matrices S over E_Σ with $f^\natural(S) = f(\mathrm{red}\, S)$ if all entries of S lie in O_Σ, and $f^\natural(S) = 0$ otherwise; $f \mapsto f^\natural$ is $\mathbb{C}$-linear. Three families are used:

(i) $\mathbf{r}$, on $I'^+ \times I^+$ matrices: the indicator of the integral S whose last row is congruent to $\mathbf{e}$;

(ii) $\mathbf{b}_y$, for $y \in ((\mathbb{Z}/N)^\Sigma)^{I'}$, on $I' \times I^+$ matrices: the indicator of the integral S whose last column is congruent to y;

(iii) $\mathbf{c}_y$, for $y \in ((\mathbb{Z}/N)^\Sigma)^I$, on $I'^+ \times I$ matrices, for E with Weil data: for integral S with last row $r = (r_i)_{i \in I}$ modulo N,

$$\mathbf{c}_y(S) = \psi_N(\textstyle\sum_{i \in I} r_i y_i),$$

and $\mathbf{c}_y(S) = 0$ for S not integral.

LEAN `IsSplitLevel.liftFn` · `IsSplitLevel.lastRowDatum` · `IsSplitLevel.lastColDatum` · `IsSplitLevel.charDatum`

Lemma 2.5. *Let I be a finite index set and R a commutative ring. There is a map k from R^{I^+} to $\mathrm{GL}_{I^+}(R)$ such that every vector y whose last entry y_* is a unit of R is both the last column and the last row of $k(y)$.*

Proof. Let y have $y_* \in R^\times$ and let C be the identity matrix with its last column replaced by y. Its determinant is y_*, and its last row is $(0, \dots, 0, y_*)$. Hence $(CC^{\mathsf T})_{i*} = \sum_a C_{ia} C_{*a} = y_i\, y_*$, the matrix $CC^{\mathsf T}$ is symmetric, and $k(y) = y_*^{-1} CC^{\mathsf T}$ is invertible with last column and last row y. For the other y put $k(y) = 1$. □

LEAN `IsSplitLevel.exists_GL_last_col_and_row` · In the Lean statement the variable y of the surrounding section is listed as an argument and not used: the statement quantifies over its own y.

Definition 2.6 (the Gauss-sum operator)**.** Let E have Weil data, let Σ be a split level for the prime N, I a finite index set and ρ a complex representation of $\mathrm{GL}_{I^+}(E_\Sigma)$. With k the map of Lemma 2.5 for $R = (\mathbb{Z}/N)^\Sigma$ (the one chosen by the formal text) and $\tilde{k}(y) = \sec(k(y))$,

$$\mathsf{F}(\rho) \;=\; \rho(u_0) \circ \sum_y \psi_N(y_*) \cdot \rho(\tilde{k}(y)),$$

the sum over the $y \in ((\mathbb{Z}/N)^\Sigma)^{I^+}$ whose last entry y_* is a unit of $(\mathbb{Z}/N)^\Sigma$. It is an endomorphism of the space of ρ: a finite Fourier transform in the last row and column, followed by u_0.

LEAN `IsSplitLevel.fourierOp`

Definition 2.7 (lift law)**.** Let E have Weil data, let Σ be a split level for the prime N, I and I' finite index sets, ρ and ρ' complex representations of $\mathrm{GL}_{I^+}(E_\Sigma)$ and $\mathrm{GL}_{I'^+}(E_\Sigma)$, L a $\mathbb{C}$-linear map from the complex functions of $I'^+ \times I^+$ matrices over E_Σ to the linear maps $\rho \to \rho'$ (we write $L[F]$ for its value at a function F), and $\varkappa \in \mathbb{C}$. We say that L is a lift law from ρ to ρ' with constant $\varkappa$ if

(i) (*integral equivariance*) for all $a \in \mathrm{GL}_{I^+}(O_\Sigma)$, $b \in \mathrm{GL}_{I'^+}(O_\Sigma)$, every function f of $I'^+ \times I^+$ matrices over $(\mathbb{Z}/N)^\Sigma$ and every vector φ of ρ:

$$\rho'(b)\Big(L\big[(T \mapsto f(\mathrm{red}(b)\, T\, \mathrm{red}(a)))^\natural\big](\rho(a)\varphi)\Big) \;=\; L[f^\natural]\,\varphi;$$

(ii) (*the law of u_0*) $\rho'(u_0)(L[\mathbf{r}]\,\varphi) = \varkappa \cdot L[\mathbf{b}_{\mathrm{e}}](\rho(u_0)\varphi)$ for every vector φ of ρ.

LEAN `IsSplitLevel.LiftLaw`

Kernels and chains.

Definition 2.8 (theta kernels and their lifts; recalled from the background library)**.** In Setting 1.2, a *theta kernel* $\mathcal{K}$ from I to I', with weights (κ, e), (κ, e'), level $K \subseteq G_f(I)$ and data in a complex vector space $\mathcal{S}$, consists of a representation ω of $G_f(I) \times G_f(I')$ on $\mathcal{S}$ in which every vector has an open stabiliser, and a linear map $\mathcal{J}$, the *jet matrix*, from $\mathcal{S}$ to the linear maps $W_\kappa(I) \to W_\kappa(I')$, such that $\mathcal{J}(\omega(\gamma, \delta)\Phi)(\gamma u) = \delta\, \mathcal{J}(\Phi)(u)$ for all rational points γ, δ of the two unitary groups,

acting on $W_\kappa(I)$, $W_\kappa(I')$ through the weights. Its *lift* with datum $\Phi \in \mathcal{S}$ is the linear map $\mathcal{A}(I;e) \to \mathcal{A}(I';e')$,

$$\mathcal{K}[\Phi](\varphi)(h) \;=\; \int_{\Gamma\backslash G_f(I)} \mathcal{J}\big(\omega(g,h)\Phi\big)\big(\varphi(g)\big)\,dg,$$

with Γ the group of rational points and the measure that gives K volume 1; the integrand is right invariant under an open subgroup, so the integral is a finite sum over classes, divided by an index. The lift is equivariant: $\mathcal{K}[\omega(a,b)\Phi](a\cdot\varphi) = b\cdot\mathcal{K}[\Phi](\varphi)$ for $a \in G_f(I)$, $b \in G_f(I')$, where $(a\cdot\varphi)(g) = \varphi(ga)$ is right translation.

Definition 2.9 (chains of lifts)**.** In Setting 1.2, let $\mathcal{K} = (\mathcal{K}_j)_j$ be the kernels and $\Phi = (\Phi_j)_j$ a family of data, $\Phi_j \in \mathcal{S}_j$. Then $\mathrm{ch}(\mathcal{K};\Phi)$ is the family of linear maps

$$\mathrm{ch}(\mathcal{K};\Phi)_j \;=\; \mathcal{K}_{j-1}[\Phi_{j-1}]\circ\ldots\circ\mathcal{K}_0[\Phi_0] \;:\; \mathcal{A}(I_0;e_0)\to\mathcal{A}(I_j;e_j),$$

the identity for $j=0$. For a family $\Phi=(\Phi_i)_i$ with $\Phi_i \in \mathcal{S}_{2i}\otimes\mathcal{S}_{2i+1}$, $\mathrm{ch}_2(\mathcal{K};\Phi)$ is the family $\mathrm{ch}_2(\mathcal{K};\Phi)_p\colon \mathcal{A}(I_0;e_0)\to\mathcal{A}(I_{2p};e_{2p})$ of the composites of the first p *pairs of lifts*, the i-th pair being the linear map that sends a pure tensor $s\otimes s'$ to $\mathcal{K}_{2i+1}[s']\circ\mathcal{K}_{2i}[s]$, evaluated at Φ_i. For a family $a=(a_j)_j$ of points $a_j \in G_f(I_j)$ and $i\ge 0$,

$$\omega^{(2)}_{\mathcal{K},i}(a) \;=\; \omega_{2i}(a_{2i},a_{2i+1})\otimes\omega_{2i+1}(a_{2i+1},a_{2i+2}),$$

an endomorphism of $\mathcal{S}_{2i}\otimes\mathcal{S}_{2i+1}$.

LEAN `chain` · `chain₂` · `twoKernelAction`

Definition 2.10 (joint invariance)**.** In Setting 1.2, let M be a complex vector space, $\mathcal{X}$ a set, $m\ge 0$, $\mathcal{X}_0\subseteq\mathcal{X}$ finite, $L_x\colon W_\kappa(I_m)\to M$ linear and $\Phi_x=(\Phi_{x,j})_j$ data, for $x\in\mathcal{X}$. The family $(L_x,\Phi_x)_{x\in\mathcal{X}_0}$ is *jointly invariant of length m for $\mathcal{K}$* if for every family $a=(a_j)_j$ with $a_j\in K_j$ for all j and $a_j=1$ for $j\ge m$, and every linear map $\beta\colon \mathcal{S}_{m-1}\otimes\cdots\otimes\mathcal{S}_0\to W_\kappa(I_m)$,

$$\sum_{x\in\mathcal{X}_0} L_x\Big(\beta\big(\textstyle\bigotimes_{j<m}\omega_j(a_j,a_{j+1})\Phi_{x,j}\big)\Big) \;=\; \sum\nolimits_{x\in\mathcal{X}_0} L_x\Big(\beta\big(\textstyle\bigotimes_{j<m}\Phi_{x,j}\big)\Big).$$

In words: the tensor $\sum_x L_x\otimes\Phi_{x,m-1}\otimes\cdots\otimes\Phi_{x,0}$ is invariant under the joint action of $\prod_{j<m}K_j$.

LEAN `IsJointlyInvariant` · In the Lean definition the family a of the surrounding section is listed as an argument and not used: the definition quantifies over its own family a of elements of the levels.

Split places inside the adelic group; names.

Definition 2.11 (embedding at a split level; determinant characters)**.** Let Σ be a finite set of finite places of E with $\overline{w}\notin\Sigma$ for $w\in\Sigma$ (in the formal text: a split level for some N) and I a finite index set. For $g\in\mathrm{GL}_I(E_\Sigma)$, $\mathrm{emb}_\Sigma(g)\in G_f(I)$ is the element whose component is g_w at each $w\in\Sigma$, the inverse of the conjugate transpose of g_w at $\overline{w}$, and 1 at the other places; $g\mapsto\mathrm{emb}_\Sigma(g)$ is a group homomorphism. For a Hecke character η of E, with local components η_w, and $k\in\mathbb{N}$, $\mathrm{dc}_{\eta,k}$ is the character

$$\mathrm{dc}_{\eta,k}(g) \;=\; \prod_{w\in\Sigma}\eta_w(\det g_w)\,|\det g_w|_w^{-k/2}$$

of $\mathrm{GL}_I(E_\Sigma)$ with values in $\mathbb{C}^\times$; here $|\cdot|_w$ is the normalised absolute value of E_w.

LEAN IsSplitLevel.embedGL · IsSplitLevel.detCharAt

Definition 2.12 (names, projections, sums of translates; the first two recalled)**.** Let E have Weil data and let V be a hermitian space over E of the kind used in this proof (in this note: $V = \mathrm{Hom}(X_I, X_{I'})$ for finite index sets I, I', whose finite adelic vectors are the $I' \times I$ matrices over $\mathbb{A}_f$). Its Weil representation has a *finite part* $\mathcal{W}_f(V)$, spanned by the translates $\varrho_f(t)\,\mathrm{vac}$ of the vacuum by the finite Heisenberg operators. For a set Σ' of finite places, $\mathrm{pr}_V^{\Sigma'}$ is the restriction to $\mathcal{W}_f(V)$ of the projection $P^{\Sigma'}$, the mean of $\varrho_f(t)$ over the integral vectors t supported above $\Sigma' \cup \overline{\Sigma'}$; its image consists of the vectors that are vacua above these places. For a split level Σ for the prime N and a function F of $I' \times I$ matrices over E_Σ, $\mathrm{nm}_\Sigma(F)$ is the endomorphism of $\mathcal{W}_f(\mathrm{Hom}(X_I, X_{I'}))$ named by F: the operator that the background library attaches to the function $t \mapsto F(t_\Sigma)$ of finite adelic matrices, t_Σ being the components of t at Σ; the map $(F, v) \mapsto \mathrm{nm}_\Sigma(F)\,v$ is bilinear. Finally, for finite index sets I, I', I'', a finite set Σ of finite places and a prime N,

$$\mathsf{T}_{N,\Sigma}(I, I', I'') \;=\; \sum_{y} \varrho_f(c(y)) \otimes \varrho_f(r(y)),$$

the sum over $y \in ((\mathbb{Z}/N)^\Sigma)^{I'}$: an endomorphism of $\mathcal{W}_f(\mathcal{H}) \otimes \mathcal{W}_f(\mathcal{H}')$ for the spaces $\mathcal{H} = \mathrm{Hom}(X_{I^+}, X_{I'})$ and $\mathcal{H}' = \mathrm{Hom}(X_{I'}, X_{I''^+})$, where $c(y)$ is the $I' \times I^+$ matrix with last column $(-[y_i/N])_{i \in I'}$ and zero elsewhere, and $r(y)$ the $I''^+ \times I'$ matrix with last row $(-\overline{[y_i/N]})_{i \in I'}$ and zero elsewhere.

The data.

Definition 2.13 (columns and stages; recalled from other notes)**.** In Setting 1.3: $\mathrm{St}_j(D)$ is the space of algebraic modular forms on $G_f(\underline{X}_j(D))$ of the weight $(\kappa_D, e_{D,j})$ that Chapter V attaches to stage j. The level $K_j^{\mathrm{col}}(D)$ consists of the $k \in K_0(\underline{X}_j(D))$ that reduce to 1 at the chosen places of D and whose last row is congruent to $(0, \dots, 0, 1)$ modulo $\pi_N(D)$; equivalently (Input 2) k lies in the chosen level and, at every $w \in \Pi(D)$, every entry of the last row of $k_w - 1$ is divisible by a uniformiser. $\mathrm{Col}(D)$ is the space of the forms of $\mathrm{St}_0(D)$ fixed by $K_0^{\mathrm{col}}(D)$, and $\mathrm{Col}^{\mathrm{ram}}(D)$ is the image of $\prod_{w \in \Pi(D)} (1 - z_w(D))$ on $\mathrm{Col}(D)$, $z_w(D)$ being right translation by the scalar matrix of an integral norm-one adele $\nu_w(D)$ that the unit *Columns* fixes for D and w, equal to 1 away from w and $\overline{w}$, whose component at w generates the units of the residue field (Input 3). The *restriction* res_D maps $\mathrm{St}_m(D)$ to algebraic forms on the definite space $Y_m(D)$ of rank one less:

$$\mathrm{res}_D(\varphi)(h) \;=\; \Big(\prod_{\tau} \tau(\overline{\pi_N(D)})^{-\mathrm{br}_D(\tau)} \Big) \cdot B_D\, \varphi(\mathrm{bd}_D(h)),$$

the product over the infinite places τ of $E(D)$, each with its embedding of the CM type; here $\mathrm{bd}_D(h) = \mathrm{diag}(h, 1)$, B_D is the integer branching matrix of the columns and $\mathrm{br}_D(\tau) \in \mathbb{Z}$ the branching exponent (Input 4).

Definition 2.14 (gauges and integral forms; recalled from the background library)**.** Let I be a finite index set, ℓ a prime and $\jmath\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism. For an infinite place τ of E, $\mathfrak{p}_\jmath(\tau)$ is the prime of E above ℓ induced by the embedding

$\jmath\circ\tau\colon E\to\mathbb{C}_\ell$, and $\mathrm{ev}_{\jmath,\tau}\colon \mathbb{A}_f\to\mathbb{C}_\ell$ is the component at $\overline{\mathfrak{p}_\jmath(\tau)}$ followed by the continuous extension of $x\mapsto \jmath(\tau(\overline{x}))$. The *gauge* of a vector $u\in W_\kappa(I)$ at $g\in G_f(I)$ is

$$\mathrm{gauge}_\jmath(g;u)\;=\;\big\|\,\varrho_{\kappa,e}\big((\mathrm{ev}_{\jmath,\tau}(g^{-1}))_\tau\big)\,\jmath(u)\,\big\|,$$

the largest ℓ-adic absolute value of a coordinate, where $\varrho_{\kappa,e}$ is the representation of $\prod_\tau \mathrm{GL}_I$ of weight (κ,e) and $\jmath$ is applied to the coordinates of u. An algebraic form φ *has gauge at most* C *at a point* $\mathsf{d}\in G_f(I)$ if $\mathrm{gauge}_\jmath(g\mathsf{d};\varphi(g))\le C$ for every $g\in G_f(I)$. For a complex space $\mathcal{V}$ of algebraic forms, $\mathrm{Int}_\jmath(\mathcal{V};\mathsf{d})$ is the $O_\jmath$-module of the $\varphi\in\mathcal{V}$ that have gauge at most 1 at d; for $\mathsf{d}=1$ these are the *$\jmath$-integral* forms. For a form φ and a ring homomorphism $\sigma\colon\mathbb{C}\to\mathbb{C}$, $\|\sigma\circ\varphi(g)\|^2_{\mathrm{W}}$ is the squared norm, for the Gram matrix of the weight, of the vector with coordinates $\sigma(\varphi(g)_i)$.

Definition 2.15 (the non-induced places and the representation at the level prime)**.** In Setting 1.3, but for any prime ℓ and ring homomorphism $\jmath\colon\mathbb{C}\to\mathbb{C}_\ell$,

$$\Sigma_\jmath(D)\;=\;\{\overline{\mathfrak{p}_\jmath(\tau)}\;:\;\tau\text{ an infinite place of }E(D)\},$$

the set of the complex conjugates of the induced primes; it depends on ℓ and $\jmath$. Now let $\ell=N(D)$ and let $\Sigma_\jmath(D)$ be a split level for $N(D)$ (which holds, Lemma 7.1). For $j\ge 0$,

$$\Delta_j(D)\;=\;\mathrm{emb}_{\Sigma_\jmath(D)}(\mathrm{dg}_{\underline{X}_j^\circ(D)}(\Pi(D)))\;\in\;G_f(\underline{X}_j(D)),$$

the point supported above $N(D)$ with component $\mathrm{diag}(1,\dots,1,N(D))$ at the $w\in\Sigma_\jmath(D)$ that divide $\pi_N(D)$ and 1 at the other $w\in\Sigma_\jmath(D)$; $\mathrm{emb}^{\Delta}_{D,j}$ is the homomorphism

$$\mathrm{emb}^{\Delta}_{D,j}\colon\;\mathrm{GL}_{\underline{X}_j(D)}(E_{\Sigma_\jmath(D)})\to G_f(\underline{X}_j(D)),\qquad g\mapsto\Delta_j(D)\cdot\mathrm{emb}_{\Sigma_\jmath(D)}(g)\cdot\Delta_j(D)^{-1};$$

and $\rho_{D,j}$ is the representation of $\mathrm{GL}_{\underline{X}_j(D)}(E_{\Sigma_\jmath(D)})$ on $\mathrm{St}_j(D)$ in which g acts by right translation by $\mathrm{emb}^{\Delta}_{D,j}(g)$.

LEAN `Data.nonInducedPlaces` · `Data.diagPointN` · `Data.conjEmbedGL` · `Data.nonInducedRep`

What is taken for granted.

Inputs from other units (as the unit's dossier reads them).

1 (unit *Columns*). The set $\Pi(D)$ of the places dividing $\pi_N(D)$ is a split level for $N(D)$.

2 (unit *Columns*). $k \in K_j^{\mathrm{col}}(D)$ if and only if k lies in the chosen level and, at every $w \in \Pi(D)$, every entry of the last row of $k_w - 1$ has valuation at most e^{-1}.

3 (unit *Columns*). For each $w \in \Pi(D)$, every ramified column φ has the form $\psi - z_w(D)\psi$ for some column ψ; the adele $\nu_w(D)$ is integral, of norm one, and equal to 1 away from w and $\overline{w}$.

4 (unit *Columns*, from the background library). The branching matrix B_D has integer entries. Over every field of characteristic zero, for every family $g = (g_\tau)$ of invertible matrices of the rank of $Y_m(D)$ and every family $s = (s_\tau)$ of non-zero scalars, indexed by the infinite places τ,

$$B_D \circ \left[\mathrm{diag}(g, s)\right]_m \;=\; \prod_\tau s_\tau^{\mathrm{br}_D(\tau)} \cdot [g]_Y \circ B_D,$$

where $[\,\cdot\,]_m$ is the action in the weight of stage m, $[\,\cdot\,]_Y$ the action in the weight of $Y_m(D)$, and $\mathrm{diag}(g, s)$ the family of the block diagonal matrices with blocks g_τ and s_τ: the exponent of s_τ is exactly the branching exponent $\mathrm{br}_D(\tau)$. Moreover B_D satisfies a size bound in the Gram norms of the two weights. The reference for this branching from rank $n+1$ to rank n is to be confirmed.

5 (the note on the index sets and characters of the data, this unit; unit *Columns*; Chapter III). The level prime $N(D)$ is congruent to 1 modulo the conductor of $E(D)$; so it splits completely in $E(D)$, each place above it has norm $N(D)$ and uniformiser $N(D)$, none is fixed by complex conjugation, and the group of infinite places permutes the places above a place of K simply transitively (Chapter III). A place dividing $N(D)$ is not a chosen place of D, and $|\underline{X}_j(D)| = n_j(D)$ is even (unit *Columns*).

Quoted from the background library (*Lib*). The catalogue of the write-up lists the following, as far as it contains them, as elementary facts or as definitions, without a reference to the literature; where a reference would be expected we write that it is to be confirmed.
Q1 (class integrals; the catalogue's file on class means). If all the groups of rational points in the conjugates of K are trivial and F is right K-invariant with values in a set A, then the integral of F over the classes is a sum of elements of A, one for each double coset; and the class integral commutes with finite sums of additive maps.
Q2 (names at split places; the catalogue's files on the mixed model). For Σ disjoint from its conjugate: the indicator of the matrices integral at Σ names the projection P^{Σ}; the name of its Schrödinger translate by a vector t is the Heisenberg translate by the part of t above $\Sigma \cup \overline{\Sigma}$, composed with P^{Σ}; and for g, h supported on $\Sigma \cup \overline{\Sigma}$ the pair Weil operator with characters a, b sends the operator named by Ψ to the one named by $\Psi(h^{-1} \cdot g)$, times the values of the space characters at the determinants at Σ and powers of their absolute values. Reference for the Schrödinger model at split places: to be confirmed.
Q3 (gauges). The gauge at g does not change when g is multiplied on the right by an element that is integral at every place above ℓ; the gauge of a sum is at most the largest gauge of a term; an integer matrix, and a Schur matrix of integral matrices, do not increase ℓ-adic norms; some rational point moves any given point, and a given conjugate of it, to points integral above ℓ (weak approximation).
Q4 (dimension of forms with free classes). If all the groups of rational points in the conjugates of a level are trivial, the space of forms of that level has dimension the number of classes times the dimension of the weight. The catalogue cites B. Gross, *Algebraic modular forms*, Israel J. Math. 113 (1999), without a place: reference to be confirmed. For the columns the groups are trivial (unit *Columns*).
Q5 (characters). The splitting character υ is unramified at every finite place; a character of the norm-one adeles with a weight and a tame part that is trivial at a place w and at $\overline{w}$ has an unramified base change at w; for an index set of even cardinality the space character of the rank twist of ν is the base change of ν.

3 Split levels and the Gauss-sum operator

Lemma 3.1 (elementary facts)**.** *Let Σ be a finite set of finite places of E, N a natural number, $y \in (\mathbb{Z}/N)^{\Sigma}$, and let $\mathbf{1}_{\Sigma} \in \mathbb{A}_f$ be the adele equal to 1 at the places of Σ and 0 elsewhere.*

(i) If N is prime, $\mathbf{1}_{\Sigma} \cdot [y/N] = [y/N]$.

(ii) Let Σ is a split level for N with N prime, $x \in O_{\Sigma}$ and $c \in (\mathbb{Z}/N)^{\Sigma}$. Then $\mathrm{red}(x) = c$ if and only if $(x_w - \tilde{c}_w)/N \in O_w$ for every $w \in \Sigma$.

(iii) If Σ is a split level for N, then Σ and its conjugate $\overline{\Sigma}$ are disjoint.

(iv) If Σ is a split level for N, then every $w \in \Sigma$ divides N.

(v) Let Σ is a split level for N with N prime, $x \in O_{\Sigma}$, $c \in (\mathbb{Z}/N)^{\Sigma}$ and $u \in \mathbb{A}_f$ such that x is the family of the components of Nu at Σ. Then $\mathrm{red}(x) = c$ if and only if $\mathbf{1}_{\Sigma} \cdot (u - [c/N]) \in \hat{O}$.

(vi) Let Σ is a split level for N with N prime, I a finite index set and Σ' a finite set of finite places. Then $\mathrm{dg}_I(\Sigma) = \mathrm{dg}_I(\Sigma \smallsetminus \Sigma') \cdot \mathrm{dg}_I(\Sigma')$.

Proof. (i) The adele $[y/N]$ vanishes outside Σ. (ii) The component of $\mathrm{red}(x)$ at w is c_w exactly when $x_w - \tilde{c}_w$ lies in the maximal ideal of O_w, which is NO_w by (c) of Definition 2.1. (iii) and (iv) are (a) and one direction of (d). (v) is (ii), since $(x_w - \tilde{c}_w)/N$ is the component at w of $u - [c/N]$ and membership in $\hat{\mathcal{O}}$ of an adele supported on Σ is tested at the places of Σ. (vi) Both sides are diagonal with last entry N at every place of Σ. □

LEAN `idem_mul_residueOverN` · `IsSplitLevel.reduction_eq_iff` · `IsSplitLevel.disjoint_star` · `IsSplitLevel.natCast_mem` · `IsSplitLevel.reduction_eq_iff_idem_mul_mem` · `IsSplitLevel.diagN_eq_sdiff_mul` · An unnamed instance records that red is a local homomorphism: an element of O_Σ with invertible reduction is a unit.

Lemma 3.2. *Let Σ is a split level for N with N prime, and let $z \in \mathbb{A}_f$. There is $b \in (\mathbb{Z}/N)^\Sigma$ such that for every $y \in (\mathbb{Z}/N)^\Sigma$:*

$$\mathbf{1}_\Sigma \cdot (z - [y/N]) \in \hat{\mathcal{O}} \quad \Longleftrightarrow \quad \mathbf{1}_\Sigma \cdot (Nz) \in \hat{\mathcal{O}} \ \text{ and } \ b = y.$$

Proof. If $\mathbf{1}_\Sigma(z - [y/N])$ is integral, so is $\mathbf{1}_\Sigma Nz = N \cdot \mathbf{1}_\Sigma(z - [y/N]) + \mathbf{1}_\Sigma(\tilde{y}_w)_w$. So if $\mathbf{1}_\Sigma Nz$ is not integral, both sides are false for every y and every b serves. If $\mathbf{1}_\Sigma Nz \in \hat{\mathcal{O}}$, let $x \in O_\Sigma$ be the family of the components of Nz at Σ and take for b its reduction, $b = \mathrm{red}(x)$. By Lemma 3.1 (v), $\mathbf{1}_\Sigma(z - [y/N]) \in \hat{\mathcal{O}}$ if and only if $\mathrm{red}(x) = y$, that is $b = y$. □

LEAN `IsSplitLevel.exists_sub_residueOverN_mem_iff` · The text reading of the census lists a character b of the surrounding section as an argument; Lean does not take it: the b of the statement is the element it provides.

Lemma 3.3 (functions of residue matrices)**.** *Let Σ be a split level for the prime N and I, I' finite index sets.*

(i) For every $I'^+ \times I^+$ matrix S over E_Σ, with u_0 in ranks I'^+ and I^+: $\mathbf{r}(u_0^{-1} S u_0) = \mathbf{b_e}(S)$.

(ii) Let f be a function of $I \times I$ matrices over $(\mathbb{Z}/N)^\Sigma$ and $g \in \mathrm{GL}_I(E_\Sigma)$ with $f^\natural(g) \neq 0$ and $f^\natural(g^{-1}) \neq 0$. Then $g = k$ for some $k \in \mathrm{GL}_I(O_\Sigma)$ with $f(\mathrm{red}\, k) \neq 0$.

(iii) If $g \in \mathrm{Mir}(I)$, then $\mathbf{b_e}(g) \neq 0$.

(iv) Let ρ, ρ' be complex representations of $\mathrm{GL}_{I^+}(E_\Sigma)$, $\mathrm{GL}_{I'^+}(E_\Sigma)$, L a linear map from functions of $I'^+ \times I^+$ matrices over E_Σ to the linear maps $\rho \to \rho'$, φ a vector of ρ, J a finite set, r a map from the $I'^+ \times I^+$ matrices over $(\mathbb{Z}/N)^\Sigma$ to J and $g\colon J \to \mathbb{C}$. Then $L[(g \circ r)^\natural]\,\varphi = \sum_{y \in J} g(y) \cdot L[(T \mapsto [r(T) = y])^\natural]\,\varphi$, where $[r(T) = y]$ is 1 if $r(T) = y$ and 0 otherwise.

Proof. (i) The matrix $u_0^{-1} S u_0$ has the entries of S, except that the last row is multiplied by N and the last column divided by N (the corner entry is unchanged). It is integral with last row $\equiv \mathbf{e}$ if and only if the entries of S outside the last column are integral, $S_{**} \equiv 1$ and S_{i*}/N is integral for $i \neq *$: that is, S is integral with last column $\equiv \mathbf{e}$, because N is a uniformiser at every place of Σ. (ii) Both g and g^{-1} have entries in O_Σ, since $f^\natural$ vanishes on non-integral matrices. (iii) is the definition of $\mathrm{Mir}(I)$. (iv) $g \circ r = \sum_y g(y)\,[r = y]$, and $f \mapsto L[f^\natural]\varphi$ is linear. □

LEAN `IsSplitLevel.lastRowDatum_conj_u₀` · `IsSplitLevel.exists_inclGL_eq` · `IsSplitLevel.lastColDatum_ne_zero` · `IsSplitLevel.liftFn_comp_eq_sum_smul` · In the last one the census lists the variable y of the section, which Lean does not take.

Lemma 3.4 (the mirabolic group and the Gauss-sum operator)**.** *Let E have Weil data, let Σ be a split level for the prime N, I a finite index set, ρ a complex representation of $\mathrm{GL}_{I^+}(E_\Sigma)$, φ a vector of ρ, T a linear endomorphism of the space of ρ and $g \in \mathrm{Mir}(I)$. Assume that $\rho(a)(T(\rho(b)\varphi)) = \varphi$ for all $a, b \in \mathrm{GL}_{I^+}(E_\Sigma)$ with $a\,g\,b \in \mathrm{Mir}(I)$. Then $T(\mathsf{F}(\rho)\varphi) = \mathsf{F}(\rho)\varphi$.*

Proof. As g and g^{-1} lie in $\mathrm{Mir}(I)$, Lemma 3.3 (iii) and (i) give $\mathbf{r}(u_0^{-1} g u_0) \neq 0$ and $\mathbf{r}(u_0^{-1} g^{-1} u_0) \neq 0$; by (ii), $u_0^{-1} g\, u_0 = k$ with $k \in \mathrm{GL}_{I^+}(O_\Sigma)$ and the last row of $\bar{k} = \mathrm{red}(k)$ equal to $\mathbf{e}$. Multiplication by $\bar{k}$ permutes the vectors y with y_* a unit and preserves y_*, because $(\bar{k}y)_*$ is the product of the last row of $\bar{k}$ with y. So, with $\tilde{k}(y)$ as in Definition 2.6,

$$\mathsf{F}(\rho)\varphi = \sum_y \psi_N(y_*)\ \rho(u_0\,\tilde{k}(\bar{k}y))\varphi, \qquad T(\mathsf{F}(\rho)\varphi) = \sum_y \psi_N(y_*)\ T(\rho(u_0\,\tilde{k}(y))\varphi),$$

and it suffices to show $T(\rho(b)\varphi) = \rho(a)^{-1}\varphi$ for $b = u_0\tilde{k}(y)$ and $a = \tilde{k}(\bar{k}y)^{-1}u_0^{-1}$. This is the hypothesis, once $a\,g\,b = \tilde{k}(\bar{k}y)^{-1}\,k\,\tilde{k}(y)$ is seen to lie in $\mathrm{Mir}(I)$: it is integral and invertible, and its reduction sends $\mathbf{e}$ first to y (the last column of $k(y)$), then to $\bar{k}y$, then back to $\mathbf{e}$ (as $k(\bar{k}y)\mathbf{e} = \bar{k}y$). □

LEAN `IsSplitLevel.mirabolic_fix_fourierOp` · Lean takes N, its primality and the split level as arguments here; the text reading of the census misses them because the statement does not write their names.

4 Lift laws: proof of Theorem A

Lemma 4.1. *In Setting 1.1, let I, I' be finite index sets, ρ, ρ' complex representations of $\mathrm{GL}_{I^+}(E_\Sigma)$, $\mathrm{GL}_{I'^+}(E_\Sigma)$, and let L is a lift law from ρ to ρ' with constant $\varkappa$; let φ be a vector of ρ.*

(i) Let $\varphi \in \mathrm{Ram}(\rho)$, $w \in \Sigma$, and let f be a function of $I'^+ \times I^+$ matrices over $(\mathbb{Z}/N)^\Sigma$ such that $f(cT) = f(T)$ for every T and every $c \in (\mathbb{Z}/N)^\Sigma$ with the property: for all $t, y \in (\mathbb{Z}/N)^\Sigma$ with $y_w = 0$, $c\,t = y$ if and only if $t = y$. Then $L[f^\natural]\,\varphi = 0$.

(ii) For $k \in \mathrm{GL}_{I'^+}(O_\Sigma)$ and $y \in ((\mathbb{Z}/N)^\Sigma)^{I'^+}$: $\rho'(k)(L[\mathbf{b}_y]\,\varphi) = L[\mathbf{b}_{\mathrm{red}(k)y}]\,\varphi$.

The property of c in (i) holds exactly for the c with $c_v = 1$ for $v \neq w$ and $c_w \neq 0$.

Proof. (i) As φ is ramified there are a unit x of O_Σ with $\mathrm{red}(x)_v = 1$ for $v \neq w$ and a vector ψ with $\varphi = \psi - \rho(x \cdot 1)\psi$. The element $c = \mathrm{red}(x)$ has the property: for $y_w = 0$ the equation $ct = y$ says $t_v = y_v$ for $v \neq w$ and $c_w t_w = 0$, and c_w is a unit. Integral equivariance, with $a = x \cdot 1$ and $b = 1$, gives $L[(T \mapsto f(cT))^\natural](\rho(x \cdot 1)\psi) = L[f^\natural]\psi$, and $f(cT) = f(T)$. Hence $L[f^\natural]\varphi = L[f^\natural]\psi - L[f^\natural]\psi = 0$. (ii) Apply integral equivariance with $a = 1$, $b = k$ to the indicator f of the matrices with last column $\mathrm{red}(k)y$: then $f(\mathrm{red}(k)T)$ is the indicator of the matrices with last column y. □

LEAN `IsSplitLevel.LiftLaw.eq_zero_of_smul_invariant` · `IsSplitLevel.LiftLaw.inclGL_lastColDatum` · In the first the census lists the section variable y, which Lean does not take; in the second Lean also takes N, its primality and the split level.

Proposition 4.2 (one law and the Gauss-sum operator)**.** *In Setting 1.1, let I, I' be finite index sets, ρ, ρ' complex representations of $\mathrm{GL}_{I^+}(E_\Sigma)$, $\mathrm{GL}_{I'^+}(E_\Sigma)$, let L is a lift law from ρ to ρ' with constant $\varkappa$ and $\varphi \in \mathrm{Ram}(\rho)$, and put*

$$C = \rho'(u_0)(L[\mathbf{c}_\mathbf{e}]\,\varphi).$$

Then

$$C \;=\; \mathsf{F}(\rho')(L[\mathbf{b}_{\mathbf{e}}]\,\varphi) \qquad \textit{and} \qquad C \;=\; \varkappa \cdot L[\mathbf{b}_{\mathbf{e}}](\mathsf{F}(\rho)\varphi).$$

Proof. For $t \in (\mathbb{Z}/N)^{\Sigma}$ let f_t be the indicator of the residue matrices T with corner entry $T_{**} = t$; then $\mathbf{c}_{\mathbf{e}} = \sum_t \psi_N(t)\, f_t^{\natural}$ by Lemma 3.3 (iv). If t is not a unit, say $t_w = 0$, then f_t is invariant under the scalars c of Lemma 4.1 (i), so $L[f_t^{\natural}]\varphi = 0$. Hence

$$L[\mathbf{c}_{\mathbf{e}}]\,\varphi \;=\; L[h^{\natural}]\,\varphi, \qquad h(T) = \psi_N(T_{**}) \text{ if } T_{**} \text{ is a unit}, \quad h(T) = 0 \text{ otherwise.} \quad (1)$$

First identity. By Lemma 4.1 (ii) and $k(y)\mathbf{e} = y$,

$$\mathsf{F}(\rho')(L[\mathbf{b}_{\mathbf{e}}]\varphi) = \rho'(u_0) \sum_{y} \psi_N(y_*)\, L[\mathbf{b}_y]\,\varphi,$$

the sum over the $y \in ((\mathbb{Z}/N)^{\Sigma})^{I'^{+}}$ with y_* a unit. A matrix with last column y has corner entry y_*, so $\sum_y \psi_N(y_*)\mathbf{b}_y = h^{\natural}$, and the right side is C by (1).

Second identity. By the law of u_0, $\varkappa\, L[\mathbf{b}_{\mathbf{e}}](\mathsf{F}(\rho)\varphi) = \rho'(u_0) \sum_y \psi_N(y_*)\, L[\mathbf{r}](\rho(\tilde{k}(y))\varphi)$, the sum over the $y \in ((\mathbb{Z}/N)^{\Sigma})^{I^{+}}$ with y_* a unit. Integral equivariance with $a = \tilde{k}(y)$, $b = 1$, applied to the indicator f of the matrices with last row y, gives $L[\mathbf{r}](\rho(\tilde{k}(y))\varphi) = L[f^{\natural}]\varphi$: indeed $Tk(y)$ has last row y if and only if T has last row $y\,k(y)^{-1} = \mathbf{e}$, the last row of $k(y)$ being y. Summing over y with the weights $\psi_N(y_*)$ gives again $h^{\natural}$, and the right side is C by (1). □

LEAN `IsSplitLevel.LiftLaw.u₀_charDatum_eq_fourierOp` · Lean also takes N, its primality and the split level.

Proof of Theorem A. Write $F = \mathsf{F}(\rho_0)$ and, for $q, j \geq 0$ and a vector ψ of ρ_0,

$$B_j^q(\psi) \;=\; L_{j-1}[\mathbf{b}_{\mathbf{e}}] \circ \ldots \circ L_0[\mathbf{b}_{\mathbf{e}}]\,(F^q\psi),$$

a vector of ρ_j.

(1) The vectors $B_j^q(\varphi)$ are ramified. Let $w \in \Sigma$ and $\varphi = \psi - \rho_0(x \cdot 1)\psi$ with x as in Definition 2.3. The scalar $x \cdot 1$ is central, so $\rho_0(x \cdot 1)$ commutes with F. Integral equivariance of L_j with $a = (x \cdot 1)^{-1}$, $b = x \cdot 1$ gives

$$\rho_{j+1}(x \cdot 1) \circ L_j[f^{\natural}] = L_j[f^{\natural}] \circ \rho_j(x \cdot 1) \qquad \text{for every } f,$$

because $f(\mathrm{red}(x)T\,\mathrm{red}(x)^{-1}) = f(T)$. By induction on j,

$$B_j^q(\varphi) = B_j^q(\psi) - \rho_j(x \cdot 1)B_j^q(\psi).$$

(2) $\mathsf{F}(\rho_j)(B_j^q(\varphi)) = (\prod_{l<j} \varkappa_l)B_j^{q+1}(\varphi)$. For $j = 0$ this is the definition. For the step, the two identities of Proposition 4.2 for the law L_j and the ramified vector $B_j^q(\varphi)$ give $\mathsf{F}(\rho_{j+1})(L_j[\mathbf{b}_{\mathbf{e}}]\, B_j^q(\varphi)) = \varkappa_j\, L_j[\mathbf{b}_{\mathbf{e}}](\mathsf{F}(\rho_j)B_j^q(\varphi))$.

(3) One pair. Let $\psi = B_{2q}^q(\varphi)$, a ramified vector of ρ_{2q}. In $\sum_y L_{2q+1}[\mathbf{c}_y]\, L_{2q}[\mathbf{b}_y]\,\psi$, a term with y zero at some place w vanishes: then $\mathbf{b}_y$ is invariant under the scalars of Lemma 4.1 (i), since for such c a column ct equals y if and only if t does. If y is non-zero at every place, then at each place some entry of y is a unit, so y is the last column of an invertible matrix over each factor $\mathbb{Z}/N$, and these assemble to $k \in \mathrm{GL}_{I^{+}_{2q+1}}((\mathbb{Z}/N)^{\Sigma})$ with $k\,\mathbf{e} = y$. With $\tilde{k} = \mathrm{sec}(k)$, Lemma 4.1 (ii) gives $L_{2q}[\mathbf{b}_y]\psi = \rho_{2q+1}(\tilde{k})\, L_{2q}[\mathbf{b}_{\mathbf{e}}]\psi$, and integral equivariance of L_{2q+1} with $a = \tilde{k}$,

$b = 1$ gives $L_{2q+1}[\mathbf{c}_y] \circ \rho_{2q+1}(\tilde{k}) = L_{2q+1}[\mathbf{c}_{\mathbf{e}}]$, because the product of a row r with $k\mathbf{e} = y$ is the product of rk with $\mathbf{e}$. So every such term equals the term of $y = \mathbf{e}$, and

$$\begin{aligned} A_q\,\psi \;&=\; d_q\,o_q \cdot \rho_{2q+2}(u_0)\,L_{2q+1}[\mathbf{c}_{\mathbf{e}}](B^q_{2q+1}(\varphi)) \;=\; d_q\,o_q \cdot \mathsf{F}(\rho_{2q+2})(B^q_{2q+2}(\varphi)) \\ &=\; d_q\,o_q \prod_{l<2q+2} \varkappa_l \cdot B^{q+1}_{2q+2}(\varphi), \end{aligned}$$

by the first identity of Proposition 4.2 for L_{2q+1} and the ramified vector $B^q_{2q+1}(\varphi)$, and by (2).

(4) The theorem follows by induction on p: it is trivial for $p = 0$, and if $A_{q-1} \circ \ldots \circ A_0(\varphi)$ is the stated multiple of $B^q_{2q}(\varphi)$, then (3) gives the statement for $q + 1$. □

LEAN `IsSplitLevel.compUpTo_pairs_eq_smul` · The census lists the section variable y, which Lean does not take.

5 Chains: proof of Theorem C

Lemma 5.1 (equivariance and linearity of chains)**.** *In Setting 1.2, let $\mathcal{K} = (\mathcal{K}_j)_j$ be the kernels.*

(i) Let $\varphi \in \mathcal{A}(I_0; e_0)$ be fixed by K_0, let $a = (a_j)_j$ with $a_j \in K_j$ for all j, $\Phi = (\Phi_j)_j$ data and $j \geq 0$. Then $\mathrm{ch}(\mathcal{K}; (\omega_i(a_i, a_{i+1})\Phi_i)_i)_j(\varphi) = a_j \cdot \mathrm{ch}(\mathcal{K}; \Phi)_j(\varphi)$.

(ii) Let $a = (a_j)_j$ be any family of points $a_j \in G_f(I_j)$, $t = (t_i)_i$ with $t_i \in \mathcal{S}_{2i} \otimes \mathcal{S}_{2i+1}$, $p \geq 0$ and $\varphi \in \mathcal{A}(I_0; e_0)$. Then

$$\mathrm{ch}_2(\mathcal{K}; (\omega^{(2)}_{\mathcal{K},i}(a)\,t_i)_i)_p(a_0 \cdot \varphi) = a_{2p} \cdot \mathrm{ch}_2(\mathcal{K}; t)_p(\varphi).$$

(iii) For $j \geq 0$, $\varphi \in \mathcal{A}(I_0; e_0)$ and $g \in G_f(I_j)$ there is a linear map β on $\mathcal{S}_{j-1} \otimes \cdots \otimes \mathcal{S}_0$ with $\mathrm{ch}(\mathcal{K}; \Phi)_j(\varphi)(g) = \beta(\Phi_{j-1} \otimes \cdots \otimes \Phi_0)$ for all data Φ.

Proof. (i) and (ii) follow by induction on the number of lifts from the equivariance of one lift (Definition 2.8): in (i) the form φ is fixed by $a_0 \in K_0$; in (ii) one first treats pure tensors $t_p = s \otimes s'$, for which the pair is $\mathcal{K}_{2p+1}[s'] \circ \mathcal{K}_{2p}[s]$, and extends by linearity. (iii) A lift is linear in its datum, so the value of the composite at φ and g is multilinear in $(\Phi_{j-1}, \ldots, \Phi_0)$. □

LEAN `chain_equivariant` · `chain₂_equivariant` · `exists_linear_chain_eq_pure` · In the last one the census lists the section variable Φ, which Lean does not take.

Proof of Theorem C. By induction on m, for all M, L, h, A and P. Let $\beta_j(g)$ be the linear map of Lemma 5.1 (iii) for φ and g, and write $\Phi_x^{<j} = \Phi_{x,j-1} \otimes \cdots \otimes \Phi_{x,0}$.

$m = 0$. The chain is the identity and $\varphi(h) = \beta_0(h)(1)$. By (e), $P_0(h, \varphi(h))$, so (f) with $\beta = \beta_0(h)$ gives $\sum_x L_x(\varphi(h)) \in A$; the empty product of class numbers is 1.

From j to $m = j + 1$. By the definition of the lift,

$$\sum_{x \in \mathcal{X}_0} L_x(\mathrm{ch}(\mathcal{K}; \Phi_x)_{j+1}(\varphi)(h)) = \int_{\Gamma \backslash G_f(I_j)} G(g)\,dg,$$

$$G(g) = \sum_{x \in \mathcal{X}_0} L_x\Big(\mathcal{J}_j(\omega_j(g, h)\Phi_{x,j})(\mathrm{ch}(\mathcal{K}; \Phi_x)_j(\varphi)(g))\Big),$$

where Q1 allows the finite sum to pass under the class integral. By Q1 and (b) it suffices to show that G is right K_j-invariant and that every $G(g)$ is a sum of $\prod_{i<j} \mathrm{cl}(K_i)$ elements of A.

Values. Fix g and apply the induction hypothesis to the same Φ and φ, the point g, the set A and the linear maps $L'_x(u) = L_x(\mathcal{J}_j(\omega_j(g,h)\Phi_{x,j})u)$ on $W_\kappa(I_j)$. For a linear β' on $\mathcal{S}_{j-1} \otimes \cdots \otimes \mathcal{S}_0$ let $T_{\beta'}$ be the linear map on $\mathcal{S}_j \otimes \cdots \otimes \mathcal{S}_0$ with $T_{\beta'}(s \otimes t) = \mathcal{J}_j(\omega_j(g,h)s)\,\beta'(t)$, so that $L'_x(\beta'(\Phi_x^{<j})) = L_x(T_{\beta'}(\Phi_x^{<j+1}))$. Joint invariance of length j for the L'_x is hypothesis (a) for the families a with $a_i = 1$ for $i \geq j$ and the maps $T_{\beta'}$. Hypothesis (f) for the L'_x and the point g: if $P_j(g, \beta'(\Phi_x^{<j}))$ for all x, then (d) gives $P_{j+1}(h, T_{\beta'}(\Phi_x^{<j+1}))$ for all x, and (f) for $\beta = T_{\beta'}$ gives $\sum_x L'_x(\beta'(\Phi_x^{<j})) \in A$. The other hypotheses are inherited. So $G(g) = \sum_x L'_x(\mathrm{ch}(\mathcal{K};\Phi_x)_j(\varphi)(g))$ is a sum of $\prod_{i<j} \mathrm{cl}(K_i)$ elements of A.

Invariance. Let $a \in K_j$ and let a' be the family with a at the index j and 1 elsewhere. By Lemma 5.1 (i),

$$\mathrm{ch}(\mathcal{K};\Phi_x)_j(\varphi)(ga) = \beta_j(g)\Big(\bigotimes\nolimits_{i<j} \omega_i(a'_i, a'_{i+1})\Phi_{x,i}\Big),$$
$$\omega_j(ga,h)\Phi_{x,j} = \omega_j(g,h)\,\omega_j(a'_j, a'_{j+1})\Phi_{x,j}.$$

Hence

$$G(ga) = \sum_{x \in \mathcal{X}_0} L_x\Big(T_{\beta_j(g)}(\bigotimes\nolimits_{i\leq j} \omega_i(a'_i, a'_{i+1})\Phi_{x,i})\Big),$$

which by (a) for the family a' equals $\sum_x L_x(T_{\beta_j(g)}(\Phi_x^{<j+1})) = G(g)$. □

LEAN `IsJointlyInvariant.sum_chain_mem_nsmul`

6 Names at a split level: proof of Theorem B

Lemma 6.1 (the embedding at a split level)**.** *Let Σ is a split level for N, I a finite index set, and for $g \in G_f(I)$ let $g_\Sigma \in \mathrm{GL}_I(E_\Sigma)$ be the family of its components at Σ.*

(i) For $g \in \mathrm{GL}_I(E_\Sigma)$: $\mathrm{emb}_\Sigma(g)_\Sigma = g$, and $\mathrm{emb}_\Sigma(g)$ has component 1 at every place outside $\Sigma \cup \overline{\Sigma}$.

(ii) Let $g \in G_f(I)$ and $a \in \mathrm{GL}_I(O_\Sigma)$ with $a = g_\Sigma$. Then the component of g at every place dividing N is integral and invertible.

(iii) Let N be prime, $w \in \Sigma$, and let ν be a finite adele with $\nu\overline{\nu} = 1$ that is integral and has $\nu_v = 1$ at every place v with $v \neq w$ and $\overline{v} \neq w$. Then there is a unit x of O_Σ with $\mathrm{red}(x)_v = 1$ for all $v \in \Sigma$, $v \neq w$, such that $\mathrm{emb}_\Sigma(x \cdot 1)$ is the scalar matrix of ν in $G_f(I)$.

Proof. (i) holds by construction. (ii) A place w dividing N lies in Σ or in $\overline{\Sigma}$, by (d) of Definition 2.1. In the first case $g_w = a_w \in \mathrm{GL}_I(O_w)$; in the second g_w is the inverse of the conjugate transpose of the component at $\overline{w}$, which is integral and invertible. (iii) Let x be the family of the components of ν at Σ; it is integral, and so is the family of the components of $\overline{\nu}$, which is its inverse because $\nu\overline{\nu} = 1$. For $v \in \Sigma$, $v \neq w$, also $\overline{v} \neq w$ by (a), so $\nu_v = 1$. The two elements $\mathrm{emb}_\Sigma(x \cdot 1)$ and the scalar matrix of ν are unitary, have component 1 outside $\Sigma \cup \overline{\Sigma}$ and the same components at Σ; so they are equal. □

LEAN `IsSplitLevel.atPlaces_embedGL` · `IsSplitLevel.embedGL_mem_supportedOn` · `IsSplitLevel.mem_integralAbove_of_inclGL_eq` · `IsSplitLevel.exists_embedGL_scalar_eq_scalarFin` · `scalarFin_atPlace` (the component at a place w of the scalar matrix of ν is the scalar matrix of ν_w; a rewriting rule, used silently)

Lemma 6.2 (Weil operators at a split level)**.** *Let E have Weil data, I, I' finite index sets, a, b characters of the norm-one adeles of E trivial on the rational points, and let $\omega_{a,b}$ be the pair Weil representation of $G_f(I) \times G_f(I')$ on $\mathcal{W}_f(\mathrm{Hom}(X_I, X_{I'}))$ with characters a, b.*

(i) For finite adeles ν, ν' of norm one, with scalar matrices $s(\nu) \in G_f(I)$, $s(\nu') \in G_f(I')$: $\omega_{a,b}(s(\nu), s(\nu')) = a(\det s(\nu'))\, b(\det s(\nu))^{-1} \cdot \omega_{1,1}(1, s(\nu'/\nu))$.

(ii) Let Σ be a split level for the prime N, $g \in \mathrm{GL}_I(E_\Sigma)$, $k \in \mathrm{GL}_{I'}(E_\Sigma)$, f a function of $I' \times I$ matrices over $(\mathbb{Z}/N)^\Sigma$ and $v \in \mathcal{W}_f(\mathrm{Hom}(X_I, X_{I'}))$. Then

$$\begin{aligned}&\omega_{a,b}(\mathrm{emb}_\Sigma(g), \mathrm{emb}_\Sigma(k))\ \mathrm{nm}_\Sigma(f^\natural)\, v \\ &\qquad = \mathrm{dc}_{\eta_b, |I'|}(g)^{-1}\ \mathrm{dc}_{\eta_a, |I|}(k) \cdot \mathrm{nm}_\Sigma(S \mapsto f^\natural(k^{-1} S g))\, v,\end{aligned}$$

where $\eta_a(x) = a(x/\overline{x})\, v(x)^{-|I|}$ and $\eta_b(x) = b(x/\overline{x})\, v(x)^{-|I'|}$ are the space characters.

(iii) In the situation of (ii), the function $t \mapsto f^\natural(t_\Sigma)$ of finite adelic matrices is the function that takes the value of f at the family of the reductions of t modulo the places of Σ if t is integral there, and 0 otherwise; it is a Schwartz–Bruhat function at Σ, so that it has a name.

Proof. (i) A pair of scalars acts on $\mathrm{Hom}(X_I, X_{I'})$ through the scalar ν'/ν; the characters contribute $a(\det s(\nu'))\, b(\det s(\nu))^{-1}$ by the definition of the twisted representation. (ii) is Q2: $\mathrm{emb}_\Sigma(g)$ and $\mathrm{emb}_\Sigma(k)$ are supported on $\Sigma \cup \overline{\Sigma}$, with components g, k at Σ (Lemma 6.1 (i)), and Σ is disjoint from its conjugate; the scalar of Q2 is the stated product of the two determinant characters. (iii) is the definition of $f^\natural$, read through the isomorphisms $\mathbb{F}_w \cong \mathbb{Z}/N$. □

LEAN `pairWeilFinite_scalarFin` · `IsSplitLevel.pairWeilFinite_name` · `IsSplitLevel.liftFn_eq_residueDatum` · `IsSplitLevel.isSchwartzBruhat_liftFn` (an instance)

Lemma 6.3 (determinant characters)**.** *Let I, I' be finite index sets and Σ a finite set of finite places of E.*

(i) Let E have Weil data and let a be a character of the norm-one adeles of E, trivial on the rational points, whose base change $x \mapsto a(x/\overline{x})$ is unramified at every $w \in \Sigma$. Then for all $i, k \in \mathbb{N}$ and $g \in \mathrm{GL}_I(O_\Sigma)$, with $\eta(x) = a(x/\overline{x}) v(x)^{-i}$: $\mathrm{dc}_{\eta,k}(g) = 1$.

(ii) Let Σ is a split level for N with N prime, Σ' a finite set of finite places, $\jmath\colon \mathbb{C} \to \mathbb{C}_N$ a ring homomorphism, η a Hecke character and $k \le k'$ natural numbers. Then $|\jmath(\mathrm{dc}_{\eta,k'}(\mathrm{dg}_I(\Sigma')))| \le |\jmath(\mathrm{dc}_{\eta,k}(\mathrm{dg}_{I'}(\Sigma')))|$.

Proof. (i) $\det g$ is a unit of O_Σ, so $|\det g_w|_w = 1$, and $\eta_w(\det g_w) = 1$ because both the base change of a and v are unramified at w (Q5). (ii) The determinant of $\mathrm{dg}_I(\Sigma')$ does not depend on the rank: its component is N at the places of $\Sigma \cap \Sigma'$ and 1 elsewhere. So the two values differ by the factor $\prod_{w \in \Sigma \cap \Sigma'} |N|_w^{-(k'-k)/2} = N^{(k'-k)\,\#(\Sigma \cap \Sigma')/2}$, because $|N|_w = N^{-1}$ for a place of norm N with uniformiser N. The square of this factor is a non-negative power of the integer N, of N-adic absolute value at most 1. □

Proof of Theorem B. Write $\mathcal{H} = \mathrm{Hom}(X_{I^+}, X_{I'})$ and $\mathcal{H}' = \mathrm{Hom}(X_{I'}, X_{I''^+})$, and let $\epsilon = \mathbf{1}_{\Sigma}$, $\epsilon' = \mathbf{1}_{\Sigma'}$. Both Σ and Σ' are split levels for N; hence $\Sigma \cup \overline{\Sigma} = \Sigma' \cup \overline{\Sigma'}$ is the set of the places dividing N, and $\epsilon + \overline{\epsilon} = \epsilon' + \overline{\epsilon'}$, $\epsilon'\overline{\epsilon'} = 0$.

Step 1: both sides are names at Σ. The projection $P^{\Sigma'}$ depends only on $\Sigma' \cup \overline{\Sigma'}$, so it equals P^{Σ}, which is named at Σ by the indicator $\mathbf{1}_{\mathrm{int}}$ of the matrices integral at Σ (Q2). The vectors $c(y)$, $r(y)$ of Definition 2.12 are supported above $\Sigma' \cup \overline{\Sigma'}$; by Q2 the operator $\varrho_f(c(y))P^{\Sigma}$ is named by the Schrödinger translate $c(y) \star \mathbf{1}_{\mathrm{int}}$, where

$$(t \star \Psi)(X) \;=\; \psi_0\big(\tfrac{1}{2}\textstyle\sum \overline{t} \cdot \epsilon\,(2X + t)\big)\,\Psi(X + t),$$

the sum over the entries; likewise for $r(y)$. So the left side of the theorem is the image of

$$Z = \sum_{y} (c(y) \star \mathbf{1}_{\mathrm{int}}) \otimes (r(y) \star \mathbf{1}_{\mathrm{int}})$$

under the linear map $\Psi \otimes \Psi' \mapsto \mathrm{nm}_{\Sigma}(\Psi)v \otimes \mathrm{nm}_{\Sigma}(\Psi')v'$, and the right side is the image of

$$Z' = \sum_{z} (S \mapsto \mathbf{b}_z(S\,\mathrm{dg}_{I}(\Sigma'))) \otimes (S' \mapsto \mathbf{c}_z(\mathrm{dg}_{I''}(\Sigma \smallsetminus \Sigma')S')).$$

(The formal text first embeds the tensor product of the finite parts into that of the ambient spaces, which is injective over a field.) A tensor of two functions is determined by its values at pairs of points, so it suffices to prove $Z(T, R) = Z'(T, R)$ for all finite adelic matrices T of size $I' \times I^+$ and R of size $I''^+ \times I'$.

Step 2: the left side at (T, R). Put $t_i = T_{i*}$ and $s_i = R_{*i}$ for $i \in I'$, and $x_i = [y_i/N]$, an adele supported on Σ'; note $\overline{x_i}\,x_i = 0$. Then

$$Z(T, R) = \sum_{y} \psi_0\Big(-\sum_{i} (\overline{x_i}\,\epsilon\,t_i + x_i\,\epsilon\,s_i)\Big) \cdot [\epsilon\,(T + c(y)) \text{ and } \epsilon\,(R + r(y)) \text{ integral}].$$

The integrality conditions concern the entries of T outside the last column and of R outside the last row, which do not involve y, and the entries $\epsilon(t_i - x_i)$ and $\epsilon(s_i - \overline{x_i})$. Let $\mathsf{p} = 1 + \epsilon'(N - 1)$, the adele equal to N on Σ' and 1 elsewhere, so that $N + 1 - \mathsf{p}$ is 1 on Σ' and N elsewhere. Applying Lemma 3.2 for the split level Σ' to the adele $\epsilon t_i + \overline{\epsilon s_i}$, and using that an adele u has ϵu and $\epsilon\overline{u}$ integral if and only if $\epsilon' u$ and $\epsilon'\overline{u}$ are, one finds $b_i \in (\mathbb{Z}/N)^{\Sigma'}$ such that for every y_i:

$$\epsilon(t_i - x_i) \text{ and } \epsilon(s_i - \overline{x_i}) \text{ integral} \iff \epsilon\,t_i\mathsf{p} \text{ and } \epsilon\,(N + 1 - \mathsf{p})s_i \text{ integral, and } y_i = b_i.$$

So every term with $y \neq b$ vanishes. The term $y = b$ can vanish as well: it is non-zero exactly when $T \cdot \mathrm{diag}(1, \dots, 1, \mathsf{p})$ and $\mathrm{diag}(1, \dots, 1, N + 1 - \mathsf{p}) \cdot R$ are integral at Σ (the formal proof records this by a case split after discarding the other terms).

Step 3: the right side at (T, R). At the places of Σ the matrix $\mathrm{dg}_{I}(\Sigma')$ is $\mathrm{diag}(1, \dots, 1, \mathsf{p})$ and $\mathrm{dg}_{I''}(\Sigma \smallsetminus \Sigma')$ is $\mathrm{diag}(1, \dots, 1, N + 1 - \mathsf{p})$. So $Z'(T, R)$ vanishes unless the same two matrices are integral at Σ; then exactly one z contributes, the reduction of the last column $(t_i\mathsf{p})_i$, and $Z'(T, R) = \psi_N(\zeta)$ with $\zeta \in (\mathbb{Z}/N)^{\Sigma}$ the reduction of $\sum_i (N + 1 - \mathsf{p})s_i \cdot t_i\mathsf{p} = N \sum_i s_i t_i$ at Σ (note $(N + 1 - \mathsf{p})\mathsf{p} = N$).

Step 4: the two characters agree. It remains to see that, for $y = b$,

$$\psi_0\Big(-\sum_{i} (\overline{x_i}\,\epsilon\,t_i + x_i\,\epsilon\,s_i)\Big) \;=\; \psi_0(-[\zeta/N]).$$

The character ψ_0 is trivial on $\hat{\mathcal{O}}$, so it suffices that the two arguments differ by an integral adele. By Step 2 the adeles $\epsilon(t_i - x_i)$ and $\epsilon(s_i - \overline{x_i})$ are integral, and by Lemma 3.1 (v), applied to $u = \sum_i s_i t_i$, $\epsilon\left(\sum_i s_i t_i - [\zeta/N]\right)$ is integral. Expanding the product $\epsilon \sum_i (t_i - x_i)(s_i - \overline{x_i})$, which is integral, and using $x_i \overline{x_i} = 0$ gives the claim. This is the computation that the formal proof closes with its last three lines. □

LEAN `IsSplitLevel.translateSum_eq_sum_name` · The formal statement takes the split level structure of Σ' as an explicit hypothesis and that of Σ as an instance.

7 The level prime of the data: proof of Theorem D

Lemma 7.1 (the non-induced places)**.** *In Setting 1.3, with $\ell = N(D)$ and $\jmath\colon \mathbb{C} \to \mathbb{C}_{N(D)}$:*

(i) $\Sigma_\jmath(D)$ is a split level for $N(D)$; in symbols, $\Sigma_\jmath(D)$ is a split level for $N(D)$.

(ii) Let $\Sigma_\jmath(D)$ carry this structure, let $j \geq 0$, Σ' a finite set of finite places of $E(D)$ and τ an infinite place of $E(D)$. Then $\mathrm{ev}_{\jmath,\tau}$, applied to the entries of $\mathrm{emb}_{\Sigma_\jmath(D)}(\mathrm{dg}_{\underline{X}^\circ_j(D)}(\Sigma'))$, gives $\mathrm{diag}(1, \dots, 1, N(D))$ if $\overline{\mathfrak{p}_\jmath(\tau)} \in \Sigma'$ and the identity matrix otherwise.

Proof. (i) By Input 5, $N(D)$ splits completely in $E(D)$: every place above $N(D)$ has norm $N(D)$ and uniformiser $N(D)$, the group of infinite places, which is the Galois group of $E(D)$ over K, permutes the places above $N(D)$ that lie over a fixed place of K simply transitively, and no place above $N(D)$ is fixed by complex conjugation. The induced places $\mathfrak{p}_\jmath(\tau)$ form one such orbit; so no induced place is the conjugate of another, and every place above $N(D)$ is an induced place or the conjugate of one. These are (a)–(d) of Definition 2.1 for the set of the conjugates. (ii) $\mathrm{ev}_{\jmath,\tau}$ reads the component at $\overline{\mathfrak{p}_\jmath(\tau)} \in \Sigma_\jmath(D)$, where the embedding places the component of the diagonal matrix (Lemma 6.1 (i)); that component has last entry $N(D)$ if $\overline{\mathfrak{p}_\jmath(\tau)} \in \Sigma'$ and 1 otherwise, and $\mathrm{ev}_{\jmath,\tau}$ fixes rational integers. □

LEAN `Data.isSplitLevel_nonInducedPlaces` · `Data.adeleExtension_map_diagN`

Lemma 7.2 (the column level is a conjugated mirabolic group)**.** *In Setting 1.3, with $\ell = N(D)$, let $\Sigma = \Sigma_\jmath(D)$ with its structure of a split level for $N(D)$, let $j \geq 0$, and for $k \in G_f(\underline{X}_j(D))$ put $k^\Delta = \left(\Delta_j(D)^{-1}\, k\, \Delta_j(D)\right)_\Sigma$, the family of the components at Σ.*

(i) For $k \in G_f(\underline{X}_j(D))$: $\mathbf{b}_\mathbf{e}(k^\Delta) \neq 0$ if and only if for every $w \in \Sigma$: k_w is integral; if $\overline{w} \in \Pi(D)$, every entry of the last row of $(k^{-1})_{\overline{w}} - 1$ is divisible by a uniformiser; and if $w \in \Pi(D)$, every entry of the last row of $k_w - 1$ is divisible by a uniformiser.

(ii) For $k \in K_j^{\mathrm{col}}(D)$: $k^\Delta \in \mathrm{Mir}(\underline{X}^\circ_j(D))$.

Proof. (i) Let $w \in \Sigma$. If $w \in \Pi(D)$, the component of $\Delta_j(D)$ at w is the diagonal matrix δ with the entries $1, \dots, 1, N(D)$, and $\delta^{-1} k_w \delta$ has the entries of k_w with the last row divided by $N(D)$ and the last column multiplied by $N(D)$. It is integral with last column congruent to the last basis vector exactly when k_w is integral and the last row of $k_w - 1$ is divisible by $N(D)$, a uniformiser. If $w \notin \Pi(D)$, then $\overline{w} \in \Pi(D)$ by Input 1 (as w divides $N(D)$), the component of $\Delta_j(D)$ at w is 1, and the condition is that k_w is integral with last column congruent to the last basis vector. Since k is

unitary, k_w is the conjugate transpose of $(k^{-1})_{\overline{w}}$, so the last column of $k_w - 1$ is the conjugate of the last row of $(k^{-1})_{\overline{w}} - 1$. (ii) By Input 2, k and k^{-1} are integral with last rows congruent to $(0, \dots, 0, 1)$ at the places of $\Pi(D)$; so (i) gives $\mathbf{b}_{\mathbf{e}}(k^{\Delta}) \neq 0$ and $\mathbf{b}_{\mathbf{e}}((k^{\Delta})^{-1}) \neq 0$, and Lemma 3.3 (ii) shows that k^{Δ} is integral and invertible with last column congruent to $\mathbf{e}$. □

LEAN `Data.lastColDatum_conj_ne_zero_iff` · `Data.atPlaces_conj_mem_mirabolic`

Lemma 7.3 (ramified columns; the operator preserves columns)**.** *In Setting 1.3, with $\ell = N(D)$ and $\Sigma_{\jmath}(D)$ with its structure of a split level for $N(D)$:*

(i) if $\varphi \in \mathrm{Col}^{\mathrm{ram}}(D)$, then $\varphi \in \mathrm{Ram}(\rho_{D,0})$;

(ii) if $\varphi \in \mathrm{Col}(D)$, then $\mathsf{F}(\rho_{D,0})\varphi \in \mathrm{Col}(D)$.

Proof. Write $\Sigma = \Sigma_{\jmath}(D)$ and $\rho = \rho_{D,0}$. (i) Let $w \in \Sigma$. It divides $N(D)$, so w or $\overline{w}$ is a place $\mathfrak{p}$ of $\Pi(D)$ (Input 1). By Input 3, $\varphi = \psi - z_{\mathfrak{p}}(D)\psi$ for a column ψ, and $\nu_{\mathfrak{p}}(D)$ is integral, of norm one and equal to 1 away from w and $\overline{w}$. By Lemma 6.1 (iii) there is a unit x of O_{Σ}, congruent to 1 at the places $v \neq w$ of Σ, with $\mathrm{emb}_{\Sigma}(x \cdot 1)$ the scalar matrix of $\nu_{\mathfrak{p}}(D)$. Scalar matrices are central, so $\mathrm{emb}^{\Delta}_{D,0}(x \cdot 1)$ is this scalar matrix too, $\rho(x \cdot 1) = z_{\mathfrak{p}}(D)$, and φ lies in the image of $1 - \rho(x \cdot 1)$.

(ii) Let $k \in K_0^{\mathrm{col}}(D)$ and let T be right translation by k; we show $T\mathsf{F}(\rho)\varphi = \mathsf{F}(\rho)\varphi$ by Lemma 3.4 with $g = k^{\Delta} \in \mathrm{Mir}(\underline{X}_0^{\circ}(D))$ (Lemma 7.2 (ii)). Let $a, b \in \mathrm{GL}_{\underline{X}_0(D)}(E_{\Sigma})$ with $a\,g\,b \in \mathrm{Mir}(\underline{X}_0^{\circ}(D))$. The operator $\rho(a)\,T\rho(b)$ is right translation by the product of $\mathrm{emb}^{\Delta}_{D,0}(a)$, k and $\mathrm{emb}^{\Delta}_{D,0}(b)$, which is $u\,k$ with

$$u \;=\; \mathrm{emb}^{\Delta}_{D,0}(a)\,k\,\mathrm{emb}^{\Delta}_{D,0}(b)\,k^{-1}.$$

The element u has component 1 outside $\Sigma \cup \overline{\Sigma}$, and $u^{\Delta} = (a\,g\,b)\,g^{-1} \in \mathrm{Mir}(\underline{X}_0^{\circ}(D))$. By Lemma 3.3 (iii) and Lemma 7.2 (i), applied to u and to u^{-1}, the element u is integral at the places above $N(D)$ with last rows congruent to $(0, \dots, 0, 1)$ at the places of $\Pi(D)$. It is supported at places above $N(D)$, none of which is a chosen place (Input 5), so it lies in the chosen level, and $u \in K_0^{\mathrm{col}}(D)$ by Input 2. Hence $u\,k \in K_0^{\mathrm{col}}(D)$ fixes the column φ, which is the hypothesis of Lemma 3.4. □

LEAN `Data.mem_ramified_of_mem_ramifiedColumns` · `Data.fourierOp_mem_column`

Lemma 7.4 (restriction to $Y_m(D)$ keeps gauges and sizes)**.** *In Setting 1.3, but for any prime ℓ with a ring homomorphism $\jmath\colon \mathbb{C} \to \mathbb{C}_{\ell}$:*

(i) Let $\mathsf{d} \in G_f(\underline{X}_m(D))$ be such that for every infinite place τ the matrix $\mathrm{ev}_{\jmath,\tau}(\mathsf{d})$ is $\mathrm{diag}(1, \dots, 1, N(D))$ if $\overline{\mathfrak{p}_{\jmath}(\tau)} \in \Pi(D)$ and the identity otherwise. Let C be a real number and $\varphi \in \mathrm{St}_m(D)$ of gauge at most C at d. Then $\mathrm{res}_D(\varphi)$ has gauge at most C at 1.

(ii) If $\ell \neq N(D)$, C is real and $\varphi \in \mathrm{St}_m(D)$ has gauge at most C at 1, then $\mathrm{res}_D(\varphi)$ has gauge at most C at 1.

(iii) For every ring homomorphism $\sigma\colon \mathbb{C} \to \mathbb{C}$, every $\varphi \in \mathrm{St}_m(D)$ and every point h of the finite adelic unitary group of $Y_m(D)$:

$$\|\sigma \circ \mathrm{res}_D(\varphi)(h)\|_{\mathrm{W}}^2 \;\leq\; \exp\Big(x^{70} - \sum_{\tau} \mathrm{br}_D(\tau) \cdot \log N(D)\Big) \cdot \|\sigma \circ \varphi(\mathrm{bd}_D(h))\|_{\mathrm{W}}^2.$$

Proof. (i) Fix h and put $g = \mathrm{bd}_D(h)$. By Definition 2.13, $\mathrm{res}_D(\varphi)(h) = s \cdot B_D\,\varphi(g)$ with $s = \prod_\tau \tau(\overline{\pi_N(D)})^{-\,\mathrm{br}_D(\tau)}$. By the identity of Input 4, applied to the inverse matrices, B_D carries the action of

$$\mathrm{ev}_{\jmath,\tau}(g\mathsf{d})^{-1} \;=\; \mathrm{ev}_{\jmath,\tau}(\mathsf{d})^{-1}\,\mathrm{ev}_{\jmath,\tau}(g)^{-1}$$

in the weight of stage m to the action of $\mathrm{ev}_{\jmath,\tau}(h)^{-1}$ in the weight of $Y_m(D)$, times the scalar $\prod_\tau \lambda_\tau^{-\,\mathrm{br}_D(\tau)}$, where $\lambda_\tau \in \{N(D), 1\}$ is the last entry of $\mathrm{ev}_{\jmath,\tau}(\mathsf{d})$. On the other hand $|\jmath(\tau(\overline{\pi_N(D)}))| = |\lambda_\tau|$: the left side is the absolute value of $\pi_N(D)$ at the place $\overline{\mathfrak{p}_\jmath(\tau)}$, which is that of $N(D)$ if this place divides $\pi_N(D)$ and 1 otherwise. So the two scalars have the same ℓ-adic size, and the gauge of $\mathrm{res}_D(\varphi)(h)$ at h is the norm of B_D applied to the vector whose norm is the gauge of $\varphi(g)$ at $g\mathsf{d}$; the integer matrix B_D does not increase norms (Q3). (ii) is (i) for $\mathsf{d} = 1$: for $\ell \neq N(D)$ no place above ℓ divides $\pi_N(D)$. (iii) The scalar s contributes $|\sigma(s)|^2 = \prod_\tau |\sigma\tau(\overline{\pi_N(D)})|^{-2\,\mathrm{br}_D(\tau)}$, and $|\sigma\tau(\overline{\pi_N(D)})|^2 = \sigma\tau(\overline{\pi_N(D)}\,\pi_N(D)) = N(D)$, because $\sigma \circ \tau$ is an embedding of the CM field $E(D)$ and so commutes with complex conjugation. The matrix B_D contributes at most $\exp(x^{70})$ by its size bound (Input 4) and the comparisons of sizes of the data (Chapter III). □

LEAN `Data.GaugeLe.restrictToY_of_diag` · `Data.GaugeLe.restrictToY` · `Data.weylNormSq_restrictToY_le` · In the first two Lean takes the prime ℓ, its primality and the homomorphism $\jmath$ as instance arguments.

Proof of Theorem D. Write $\Sigma = \Sigma_\jmath(D)$, $\rho = \rho_{D,0}$, $F = \mathsf{F}(\rho)$, $\Delta = \Delta_0(D)$, and for a finite set Σ' of places $\mathsf{d}(\Sigma') = \mathrm{emb}_\Sigma(\mathrm{dg}_{\underline{X}_0^\circ(D)}(\Sigma'))^{-1}$; so $\Delta\,\mathsf{d}(\Pi(D)) = 1$. For an index a of $\underline{X}_0(D)$ let $t(a)$ be the sum, over the classes of $K_0^{\mathrm{col}}(D)$, the coordinates i of the weight and the infinite places τ, of the number of times a occurs in the tableau that names the coordinate i at τ.

Step 1. For every Σ': every finite family in $\mathrm{Int}_\jmath(\mathrm{Col}(D); \Delta\mathsf{d}(\Sigma'))$ is carried into $\mathrm{Int}_\jmath(\mathrm{Col}(D); \Delta)$ by a square matrix over $O_\jmath$ whose determinant divides $N(D)^{\,t(*)}$. Indeed, a column is determined by its values at representatives of the classes, which are arbitrary vectors of the weight because the rational points act freely (Q4); adjust each representative by a rational point so that it, and its conjugate by $\mathsf{d}(\Sigma')$, are integral above $N(D)$ (Q3). In these coordinates, by Lemma 7.1 (ii), a column that is integral at $\Delta\mathsf{d}(\Sigma')$ becomes integral at Δ after its coordinate i at a class is multiplied by $N(D)$ to the number of occurrences of the last index in the tableaux of i: the action of $\mathrm{diag}(1, \dots, 1, N(D))$ in the weight is diagonal with these powers of $N(D)$, up to an integral Schur matrix (Q3). The determinant of this diagonal map is $N(D)^{\,t(*)}$.

Step 2. For $q \geq 0$, every finite family in $\mathrm{Int}_\jmath(\mathrm{Col}(D); 1)$ is carried by a matrix over $O_\jmath$ of determinant dividing $N(D)^{\,t(*)(q+1)}$ into the forms ψ with $F^q\psi \in \mathrm{Int}_\jmath(\mathrm{Col}(D); \Delta)$. For $q = 0$ this is Step 1 with $\Sigma' = \Pi(D)$. For the step it suffices, by Step 1 with $\Sigma' = \Sigma$ and by composing matrices, that F maps $\mathrm{Int}_\jmath(\mathrm{Col}(D); \Delta)$ into $\mathrm{Int}_\jmath(\mathrm{Col}(D); \Delta\mathsf{d}(\Sigma))$. Let ψ be in the former. Then $F\psi$ is a column (Lemma 7.3 (ii)), and it is a sum of terms $\psi_N(y_*) \cdot \rho(u_0\,\tilde{k}(y))\psi$; the gauge of a sum is at most the largest gauge of a term, and $|\jmath(\psi_N(y_*))| = 1$ since $\psi_N(y_*)$ is a root of unity. The value of $\rho(u_0\tilde{k}(y))\psi$ at g is $\psi(g')$ with $g' = g\,\Delta\,\mathsf{d}(\Sigma)\,\mathrm{emb}_\Sigma(\tilde{k}(y))\,\Delta^{-1}$, and $g'\Delta = g\Delta\mathsf{d}(\Sigma) \cdot \mathrm{emb}_\Sigma(\tilde{k}(y))$, where the last factor is integral above $N(D)$ (Lemma 6.1 (ii)). So the gauge of this value at $g\Delta\mathsf{d}(\Sigma)$ is its gauge at $g'\Delta$ (Q3), at most 1.

Step 3. Take $q = \varrho(D) + 1$ and $e = t(*)\,(\varrho(D) + 2)$. To bound e: $t(a) = t(b)$ for all indices a, b, by the symmetry of the weight under permutations of the coor-

dinates; and $\sum_a t(a)$ is the number of classes times the number of coordinates times the sum over τ of the number of boxes of the weight at τ, which is at most $a(D)$ for each τ (unit *Columns*). The number of classes times the number of coordinates is $\dim_{\mathbb{C}} \mathrm{Col}(D)$ (Q4). Hence $t(*) \le \dim_{\mathbb{C}} \mathrm{Col}(D) \cdot f(D)\, a(D)/n_0(D)$, and $e \le 4\, m\, f(D)\, b \dim_{\mathbb{C}} \mathrm{Col}(D)$ is one of the comparisons of sizes of the data. □

LEAN `Data.exists_indexDvd_fourierOp_pow` · The split level is an explicit argument of the Lean statement, with Lemma 7.1 (i) as its default value.

Lemma 7.5 (the characters of the chain above the level prime)**.** *In Setting 1.3, let ϑ be a tame character of D and, for $i \ge 0$, let $\mu_{D,i}(\vartheta^i)$ be the character of lift i (the product of the base character $\mu^0_{D,i}$ and ϑ^i).*

(i) For $j \ge 0$, a finite index set I and a finite place w of $E(D)$ dividing $N(D)$: the base change of the rank twist $\mu_{D,j}(\vartheta^j)\, \upsilon^{\lfloor |I|/2 \rfloor}$ is unramified at w.

(ii) For $j, i \ge 0$: the space character, in rank $|\underline{X}_j(D)|$, of the rank twist of $\mu_{D,i}(\vartheta^i)$ for $\underline{X}_j(D)$ is the base change $x \mapsto \mu_{D,i}(\vartheta^i)(x/\overline{x})$.

Proof. (i) The tame part of $\mu_{D,j}(\vartheta^j)$ is trivial at w and at $\overline{w}$: these places are not chosen (Input 5) and do not belong to the set $Q(\vartheta)$, whose places have norm prime to $N(D)$; and υ is unramified. Apply Q5. (ii) is Q5, as $|\underline{X}_j(D)| = n_j(D)$ is even (Input 5). □

LEAN `Data.charUnramifiedAt_rankTwist_of_N_mem` · `Data.spaceChar_rankTwist`

8 Where the results are used

Theorem A, Theorem B, Lemma 6.2 (ii), Lemma 6.3 and Lemma 7.3 (i) are used together in the unit *Columns*, in the file that trades denominators at the level prime for a column operator: there the chain of pairs of lifts whose data are the translates of Theorem B is rewritten, by Theorem B and then Theorem A with $\rho_j = \rho_{D,j}$ and the laws given by the lifts of the definite chain, as a constant times the chain with the simplest data applied to $\mathsf{F}(\rho_{D,0})^{\varrho(D)+1}$. Theorem D and Lemma 7.4 enter the local statement at the level prime in the same unit. Theorem C is used in *Columns* (the chain of a good datum is a plain sum over classes, which gives its integrality) and in the unit *Exchange*, together with Lemma 5.1 (i), (iii). Lemma 5.1 (ii), Lemma 6.2 (i) and Lemma 7.5 (i) are used in the note on the seesaw identity, to show that a central element at a place dividing $\pi_N(D)$ acts trivially on a chain of pairs. The definitions of chains, of joint invariance and of $\mathsf{T}_{N,\Sigma}(I, I', I'')$ are part of the definition of a good datum (unit *Columns*), and $\omega^{(2)}_{\mathcal{K},i}(a)$ occurs in the proof of the seesaw identity.

9 Notes on the formal text

Arguments that the census lists and Lean does not take. The census of the workspace reads the arguments of a declaration from its text. In the files treated here a section declares variables (a vector y of residues, a family a of points, data Φ, a character b); the text reading lists such a variable as an argument whenever its name occurs in a statement, also when the occurrence is bound there. This concerns the vector y in the Gauss-sum operator, in the section of the split level, in Lemma 2.5, Lemma 3.3 (iv), Lemma 4.1 (i) and Theorem A; the family a in the definition of joint

invariance; the data Φ in Lemma 5.1 (iii); the character b in Lemma 3.2. Nothing was compiled for this note, so Lean's own answer is not recorded; the statements above follow the Lean text.

Arguments that Lean takes and the census misses. A lift law is defined for a split level Σ for a prime N, and so are the mirabolic group, the function $f^\natural$ and the Gauss-sum operator; the statements of Definition 2.7, Lemma 3.4, Lemma 4.1 (ii) and Proposition 4.2 therefore take N, its primality and the split level, although their text does not name them. The embedding $\mathrm{emb}_\Sigma(g)$ uses only that Σ is disjoint from its conjugate, but takes a split level. The set $\Sigma_\jmath(D)$ and Lemma 7.4 (i) take a prime ℓ and a homomorphism $\jmath$ that their names do not show.

A boundary case. The adele $[y/N]$ is defined in the formal text for every natural number N, with no hypothesis on Σ. The description by the representative in $\{0, \dots, N-1\}$ is the case $N > 0$; for $N = 0$ division by zero returns zero in Lean, so the adele is zero. Every use in this note has N prime.

Choices. The section sec, the map k of Lemma 2.5 and hence the matrices $\tilde{k}(y)$ in the Gauss-sum operator are chosen once (by the axiom of choice). The proofs use only that $\mathrm{red} \circ \mathrm{sec}$ is the identity and that $k(y)$ has last row and last column y; a different choice changes $\mathsf{F}(\rho)$ on vectors that are not fixed by the principal congruence subgroup of level N.

Statements more special or more general than their use. Part (ii) of Lemma 6.3 compares two ranks I, I' although the value does not depend on the rank. In Theorem C the properties P_j are arbitrary and serve as an induction hypothesis carried along the chain; hypothesis (b) (free classes) is what turns class integrals into sums. In Theorem D the exponent $\varrho(D) + 1$ is the number of pairs of lifts; the proof gives the statement for every power q with the exponent $t(*)(q+1)$. Lemma 6.2 (ii) is stated in the dossier with the function $S \mapsto f(k^{-1}Sg)$ of residue matrices; the Lean text has the function $S \mapsto f^\natural(k^{-1}Sg)$ of matrices over E_Σ, which is not of the form $f'^\natural$ when g or k is not integral, and this is the form used above.

Members that act implicitly. Some members of this note are rewriting rules that no proof cites by name: the formula for the components of $[y/N]$ (Definition 2.1) and the components of a scalar matrix (Lemma 6.1). An unnamed instance (the reduction is a local homomorphism) is mentioned after Lemma 3.1.

How this note was written. From the unit's dossier: the statements in words and the structured proofs of the members of the two files (for the members that have a proof tree). Both Lean files were read completely in the source at the pinned commit, and every statement above was compared with its Lean text argument by argument; this is how the difference in Lemma 6.2 (ii) was found. The dossier's reader marks the claims for the long proofs of Theorem B and of Theorem D as read from lemma names. Both proofs were read line by line in the Lean source for this note; the computation with the two additive characters in Step 4 of Theorem B and the three steps of Theorem D are written from that reading. The proofs of Theorem A, Proposition 4.2 and Lemma 3.4 were checked by hand as written here;

they are shorter than the formal ones, which carry out the same re-indexings through rewriting. Of the background library, the definitions of kernels and lifts, of gauges and integral forms, of the Schrödinger action and of names were read in the source; their properties Q1–Q5 are quoted, not read. The inputs from the unit *Columns* are stated as the dossier's imports read them. The program check of the unit's dossier covered 503 leaf steps of 83 proofs.

Revision. After an independent referee's report, Input 4 states the identity of the branching matrix with its exact exponent, read in the Lean source of the unit *Columns* and of the library, and the central adele and its translation carry the data: $\nu_w(D)$, $z_w(D)$.

Legend: in the Lean text the set Σ of places is `P` and Σ' is `S`; the index sets I, I', I'' are `n`, `n'`, `m`, and I^+ is the sum of `n` and a one-point type; the representations ρ, ρ' carry the Greek letter pi and the constant $\varkappa$ of a law the letter gamma; $f^\natural$ is `liftFn f`; $\mathbf{r}$, $\mathbf{b}_y$, $\mathbf{c}_y$ are `lastRowDatum`, `lastColDatum y`, `charDatum y`; u_0 is `diagNInv`; the ring homomorphism $\jmath$ is the field of the class `PadicPlace`.

Two statements as they stand in the artifact, the class of split levels and the Gauss-sum operator:

```
class IsSplitLevel (P : Finset (FinPlace E)) (N : outParam ℕ) where
  star_notMem : ∀ w ∈ P, star w ∉ P
  q_eq : ∀ w ∈ P, w.q = N
  protected v_natCast : ∀ w ∈ P, v (N : LocField w) = exp (-1)
  natCast_mem_iff w : ↑N ∈ w.1 ↔ w ∈ P ∨ star w ∈ P
```

```
def fourierOp := π.ρ diagNInv * ∑ y with IsUnit (y (.inr ())),
  psiN (y (.inr ())) • π.ρ (inclGL (liftGL (exists_GL_last_col_and_row.choose y)))
```

Notation

E, K a CM field with a CM type; in Setting 1.3, $E = E(D)$ over the imaginary quadratic field

$\mathbb{A}_f$, $\hat{\mathcal{O}}$ finite adeles of E; their integers

w, v, $\overline{w}$ finite places of E; the conjugate place

E_w, O_w, $\mathbb{F}_w$, $\mathrm{N}w$ completion, its integers, residue field, norm

$\mathbf{j}$, α, υ the Weil data: an element, an idele, the splitting character

ψ_0, ψ_f the standard finite additive characters

N a prime number (the level prime $N(D)$ for the data)

Σ, Σ' finite sets of finite places; split levels

E_Σ, O_Σ, $(\mathbb{Z}/N)^\Sigma$ product of completions; integral elements; residue ring

$[y/N]$, $\psi_N(y)$, $\tilde{y}$ the adele $\tilde{y}/N$ on Σ; its character value; least representative

$\mathbf{1}_\Sigma$, ϵ, ϵ' the adele that is 1 on a set of places; those of Σ, Σ'

I, I', I'', I_j, J finite index sets; $I^+ = I \sqcup \{*\}$, $*$ the last index

red, sec reduction modulo N; a chosen section on matrices

$\mathbf{e}$ the last basis vector

$\mathrm{dg}_I(\Sigma')$, u_0 diagonal matrix with last entry N at $\Sigma \cap \Sigma'$; the inverse for $\Sigma' = \Sigma$

$\mathrm{Mir}(I)$, $\mathrm{Ram}(\rho)$ the mirabolic group; ramified vectors

ρ, ρ', ρ_j complex representations of $\mathrm{GL}_{I^+}(E_\Sigma)$

φ, ψ vectors of a representation; algebraic forms

f, $f^\natural$, h, f_t functions of residue matrices; extension by zero

$\mathbf{r}$, $\mathbf{b}_y$, $\mathbf{c}_y$ indicator of the last row; of a last column; character of a last row

$k(y)$, $\tilde{k}(y)$, C the matrix of Lemma 2.5; its lift; an auxiliary matrix or a real bound

$\mathsf{F}(\rho)$, F the Gauss-sum operator

L, L_j, $\varkappa$, $\varkappa_j$ lift laws and their constants

A_i, d_i, o_i, p, q, l the pair operators, scalars, counts; numbers of pairs; an index

B_j^q, T, S, S', R, r, t, c, x, y, z, u, a, b, g, k auxiliary operators, matrices, residues, units and group elements, as introduced where used

$G_f(I)$, $K_0(I)$, X_I finite adelic unitary group of the standard space X_I; stabiliser of its lattice

κ, e_j, $W_\kappa(I)$, $\mathcal{A}(I;e)$ weight, last entries, space of the weight, algebraic forms

$\mathcal{K}_j$, ω_j, $\mathcal{J}_j$, $\mathcal{S}_j$, K_j kernels: representation, jet matrix, data space, level

Φ, Φ_x, $\mathrm{ch}(\mathcal{K};\Phi)$, $\mathrm{ch}_2(\mathcal{K};\Phi)$ data; chains of lifts and of pairs

$\omega^{(2)}_{\mathcal{K},i}(a)$ the joint action on the data of a pair

M, $\mathcal{X}$, $\mathcal{X}_0$, L_x, A, P_j, β, G, Γ in Theorem C: target space, index set, linear maps, a subset, properties, a linear map, the integrand, rational points

γ, δ rational points, in the definition of a kernel; δ also a diagonal matrix

$\mathrm{cl}(K)$, m, n, i, j number of classes; natural numbers

$\mathrm{emb}_\Sigma(g)$, g_Σ embedding at a split level; components at Σ

η, $\mathrm{dc}_{\eta,k}$, ν, ν' a Hecke character; the determinant character; norm-one adeles

V, $\mathcal{H}$, $\mathcal{W}_f(V)$, ϱ_f hermitian spaces; finite part; finite Heisenberg operators

$\mathrm{pr}_V^{\Sigma'}$, $\mathrm{nm}_\Sigma(F)$ projection to vacua above $\Sigma' \cup \overline{\Sigma'}$; named operator

$\mathsf{T}_{N,\Sigma}(I, I', I'')$ the sum of pairs of translates with denominator N

$\mathfrak{p}$, ζ, Z, Ψ, X in the proof of Theorem B: an adele, a residue, tensors of functions, functions, a matrix

$P = (N_0, d)$, D parameters; admissible data

x, x_1, b, μ, m, r, g_0, g_1, π_g components of D (also local letters, as said)

$N(D)$, $\pi_N(D)$, $\Pi(D)$ the level prime; $\pi_N(D)\overline{\pi_N(D)} = N(D)$; the places dividing $\pi_N(D)$

$f(D)$, $a(D)$, $n_j(D)$, $\varrho(D)$ number of infinite places; a size; ranks; $m = 2\varrho(D) + 2$

$\underline{X}_j(D)$, $\underline{X}^\circ_j(D)$, $X_j(D)$, $Y_m(D)$ index sets; the definite spaces

$\mathrm{St}_j(D)$, $K_j^{\mathrm{col}}(D)$, $\mathrm{Col}(D)$, $\mathrm{Col}^{\mathrm{ram}}(D)$ forms of stage j; its level; columns; ramified columns

$\nu_w(D)$, $z_w(D)$, $\mathfrak{p}$ the central adele of D at a place w of $\Pi(D)$; its translation; such a place (without D, ν_w is the component at w of an adele ν)

res_D, bd_D, B_D, $\mathrm{br}_D(\tau)$, s, λ_τ restriction; $h \mapsto \mathrm{diag}(h, 1)$; branching matrix; exponents; scalars

τ, σ an infinite place with its embedding; a ring homomorphism $\mathbb{C} \to \mathbb{C}$

ℓ, $\jmath$, $O_\jmath$ a prime; a ring homomorphism $\mathbb{C} \to \mathbb{C}_\ell$; its valuation ring in $\mathbb{C}$

$\mathfrak{p}_\jmath(\tau)$, $\mathrm{ev}_{\jmath,\tau}$ the induced prime; evaluation of adeles at its conjugate

$\mathrm{gauge}_\jmath(g;u)$, $\mathrm{Int}_\jmath(\mathcal{V};\mathrm{d})$, $\|\cdot\|^2_{\mathrm{W}}$ gauge; integral forms at a point; Gram norm

$\Sigma_\jmath(D)$, $\Delta_\jmath(D)$, Δ, δ non-induced places; the diagonal point; a diagonal matrix

$\mathrm{emb}_{D,j}^{\Delta}$, $\rho_{D,j}$, k^{Δ} conjugated embedding; the representation on stage j; conjugated components

d, $t(a)$, e a point; tableau counts; the exponent of Theorem D

ϑ, $Q(\vartheta)$, $\mu_{D,i}(\vartheta^i)$, $\mu_{D,i}^0$ a tame character, its set of places, the characters of the lifts

READBACK NOTE 24

The characters, the level prime and the index sets of the data; the grid spaces

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. Besides scales and ranks, the data D of the argument carry a list of chosen objects from which the automorphic forms of Chapters V to VII are built. This note fixes them: the chosen places above the two primes g_0, g_1 and the residue characters there; three characters of the norm-one group U(1) with their weights and tame parts; the level, a prime $N(D)$ in a short window, with an integer of norm $N(D)$; tame characters and twists; the index sets of the hermitian spaces of the chain of theta lifts, the finite group $\mathsf{G}(D)$ and its idempotent; and the spaces, characters and levels on the two grids of lifts of Chapter VII. Three statements have content: the level exists and $m \log b \le \log N(D) \le 30\, m \log b$ (Theorem A); the characters exist, by Weil's criterion for algebraic Hecke characters (Theorem B); and for interlacing weights there is an integral pairing that computes periods over a definite unitary group as finite means (Theorem C).

What this note is. The artifact grh-compact is a body of Lean code whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. That is a claim: its authors report that Lean's kernel accepts the code; the record of checks of this write-up says who has built what; nothing was compiled for this note, and no mathematician has read the proof through. This note is one of four on one unit, the folder of the seesaw identity (Chapter V): it treats 88 of the unit's 312 declarations, those of the file of index types and of the file of the grid spaces, which are vocabulary for other units; the notes *The seesaw identity for the chain of theta lifts*, *Two consecutive theta lifts* and *Chains of definite theta lifts and the Gauss-sum operator* treat the rest. Every statement below was compared, argument by argument, with the Lean text. Proofs are given in full, except that results of other units and of the background library are quoted as *Inputs*, each with its owner. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 88 declarations.

1 The statements

The notation is that of Section 2. In particular D is admissible data for parameters $P = (N_0, d)$, with scales x, x_1, b, exponent μ and number of lifts m; $E(D)$ is its CM field, with infinite places τ; $w_{D,j}(\tau)$ are the weights of Chapter III; and $\mathrm{tar}(D)$, $N(D)$, $\pi_N(D)$, $\omega_{D,w}$, $\mu^0_{D,j}$, $\mu_{D,j}(\vartheta)$, $\psi_{D,j}(\vartheta)$ are defined in Sections 3 to 6.

Theorem A (the level). In Setting 2.1, for parameters P and admissible data D for P:

(i) $m \log b \le \mathrm{tar}(D) \le 29\, m \log b$;

(ii) $N(D)$ is a prime number, $N(D) \equiv 1$ modulo $N_1(D)\, d$, and

$$\mathrm{tar}(D) \le \log N(D) \le \mathrm{tar}(D) + \sqrt{\log b}, \qquad m \log b \le \log N(D) \le 30\, m \log b;$$

(iii) there is an integer π of $E(D)$ with $\pi\,\overline{\pi} = N(D)$, and $\pi_N(D) \cdot \overline{\pi_N(D)} = N(D)$.

LEAN `Data.logLevelTarget_mem_Icc` · `Data.N_prime` · `Data.N_modEq_one` · `Data.log_N_mem_window` · `Data.log_N_mem_Icc` · `Data.exists_pi_mul_star` · `Data.π_mul_star`

Theorem B (the characters). In Setting 2.1, for parameters P and admissible data D for P:

(i) for all natural numbers c and n there is a character of $\mathrm{U}(1)$ of $E(D)$ (a continuous character of the norm-one adeles, trivial on the norm-one elements of $E(D)$) of weight $\tau \mapsto -c \cdot w_{D,0}(\tau)$ and tame part $(\omega_{D,w}^{n})_w$;

(ii) for every natural number j, the character $\mu_{D,j}^{0}$ has weight $\tau \mapsto -w_{D,j}(\tau)$ and tame part $(\omega_{D,w}^{j})_w$;

(iii) for every tame character ϑ of D and every natural number j, the character $\mu_{D,j}(\vartheta)$ has weight $\tau \mapsto -w_{D,j}(\tau)$ and tame part $\psi_{D,j}(\vartheta)$.

LEAN `Data.exists_char_hasWeight` · `Data.mu₀_hasWeight` · `Data.hasWeight_liftChar`

Theorem C does not involve the data. A *weight* for a CM field E is a pair (κ, e): for every infinite place τ of E a function $\kappa_\tau\colon \mathbb{N} \to \mathbb{N}$ (the number $\kappa_\tau(h)$ of columns of height h of a Young diagram) and an integer e_τ. In rank N its *doubled Harish-Chandra parameter* is

$$\mathrm{hc}_{\kappa,e}^{N}(\tau, p) = 2\Big(e_\tau + \sum_{p<h<N} \kappa_\tau(h)\Big) + N - 1 - 2p \qquad (0 \le p < N),$$

and a family $l = (l_\tau)$ of maps from an index set of N elements to $\mathbb{Z}$ *is the doubled Harish-Chandra parameter of* (κ, e) if every l_τ is injective and its values, in decreasing order, are $\mathrm{hc}_{\kappa,e}^{N}(\tau, 0), \dots, \mathrm{hc}_{\kappa,e}^{N}(\tau, N-1)$. The representation $\rho_{\kappa,e}$, the Weyl norm $\|\cdot\|$, the functions $F_\eta^{l,\mathrm{s}}$ and the mean $\mathrm{mean}_{\mathcal{X}}(\cdot)$ are recalled in Section 8.

Theorem C (branching pairing). Let E be a CM field with a CM type, n a non-empty finite index set and n' a finite index set, (κ, e) and (κ', e') weights for E, $l = (l_\tau)$ and $l' = (l'_\tau)$ families of maps $l_\tau \colon n \to \mathbb{Z}$, $l'_\tau \colon n' \to \mathbb{Z}$, $\sigma \colon n \sqcup \{*\} \to n'$ a bijection, and $\mathbf{s}$, $\mathbf{r}$, $\mathbf{t}$ signs on n, on $\{*\}$ and on n'. Suppose that $(\mathbf{s} \sqcup \mathbf{r}) \circ \sigma^{-1} = \mathbf{t}$ and $\mathbf{t} = 1$; that l' is the doubled Harish-Chandra parameter of (κ, e) and $-l$ is the doubled Harish-Chandra parameter of (κ', e'); and that l and l' interlace: for every infinite place τ and every integer y,

$$\#\{j \in n' : y < l'_\tau(j)\} - \#\{i \in n : y < l_\tau(i)\} \in \{0, 1\}.$$

Then there is a matrix B with integer entries, from coordinates of weight κ in rank $|n'|$ to coordinates of weight κ' in rank $|n|$, with the following properties.

(a) There are integers N_τ, one for each infinite place τ, such that:

(1) for all commutative rings S with an involution, all fields R of characteristic 0, all families of ring homomorphisms $f_\tau \colon S \to R$, all $g \in \mathrm{U}_n(S)$, $u \in \mathrm{U}_1(S)$ and all vectors v', v over R,

$$\langle \rho_{\kappa', e'}(f(g))v',\, B\, \rho_{\kappa, e}(f(\mathrm{diag}_\sigma(g, u)))v \rangle = \prod_\tau f_\tau(\det u)^{N_\tau} \cdot \langle v', Bv \rangle;$$

(2) $|N_\tau| \le \mathrm{boxes}(\kappa, |n'|) + |e_\tau|$ for every τ;

(3) for every natural number $M \ge \mathrm{boxes}(\kappa, |n'|)$ and all complex vectors v', v: $|\langle v', Bv \rangle| \le (M^M)^3 \, \|v'\| \, \|v\|$.

(b) For every point $g = (g_\tau)_\tau$ of the product, over the infinite places, of the real unitary groups of the signs $\mathbf{t}$ there is a complex number C such that for every standard hermitian space V with index set n and signs $\mathbf{s}$, all algebraic forms η of weight (κ', e') in rank $|n|$ and ϕ of weight (κ, e) in rank $|n'|$, every $u \in \mathrm{U}_1(\mathbb{A}_f)$ and every level $\mathcal{K} \subseteq \mathrm{U}_n(\mathbb{A}_f)$,

$$\int_{[\mathrm{U}(V)]} F_\eta^{-l, \mathbf{s}}(y) \cdot F_\phi^{l', \mathbf{t}}(\mathrm{diag}_\sigma(y, (1, u)) \cdot (g, 1))\, dy = \frac{C}{[\mathcal{K}_0 : \mathcal{K}]} \cdot \mathrm{mean}_{\mathcal{K}}(h \mapsto \langle \eta(h), B\, \phi(\mathrm{diag}_\sigma(h, u)) \rangle).$$

LEAN `exists_branching_pairing`

2 The setting

Conventions. Throughout, P denotes parameters and D admissible data for P; Setting 2.1 recalls what these are, and every statement that takes D as an argument cites it. The letter τ denotes an infinite place of the field $E(D)$ and w a finite place of it; $i \in \{0, 1\}$ numbers the two primes g_0, g_1 of D. A stage is a natural number j; ϑ is a tame character of D (Definition 6.1), in Section 9 an m-fold twist; ψ is a family $(\psi_w)_w$ of characters of the residue fields of $E(D)$. In Definition 7.1 and Lemma 7.2, S, T and α are sets. In Theorem C, E is a CM field, n and n' are finite index sets, n non-empty, and κ, κ', e, e', l, l', $\mathbf{s}, \mathbf{r}, \mathbf{t}$, σ are as stated there; in Lemma 9.7, n and n' are finite index sets. In Section 9, z and c are elements of $\{0, 1\}$, I is a set, and

i, i', j, j', a, b, l are natural numbers. Every other letter is bound by the statement that uses it.

Setting 2.1 (parameters and data)**.** *Parameters* are a pair $P = (N_0, d)$: a positive multiple N_0 of 18480 and a prime $d \equiv N_0/2 - 1$ modulo N_0; put $K(P) = \mathbb{Q}(\sqrt{-d})$. *Admissible data* for P are a record D with these components: real scales x, x_1, b; natural numbers μ (the exponent), m (the number of lifts) and r (the rank); a set $\mathrm{thick}(D)$ of infinite places of the field $E(D)$ below; two primes $g_0 \neq g_1$; and an integer π_g of $K(P)$ with $\pi_g \overline{\pi_g} = g_0 g_1$. They satisfy the conditions of Chapter III. This note uses the following ones, in which $C(P) \geq 64$ is the constant of P of Chapter III:

(D1) the scales satisfy $10^{12}\, C(P) \leq \log\log b$, $100 \log\log b \leq \log x$, $10^6 \log x \leq \log x_1$ and $10^6 \log x_1 \leq \log b$;

(D2) m is a power of 2, $m \geq 2$, and $2^\mu = m^{22}$; $\sqrt{x} \leq m \leq 2\sqrt{x}$; $\mu \leq 32 \log x$; r is a power of 3 with $x^5 \leq r \leq 3x^5$;

(D3) for $i \in \{0, 1\}$: $g_i \equiv 1$ modulo $N_1(D)\, d$, the square of $M_\omega(P, \mu)$ divides $g_i - 1$, and $b^{10} \leq g_i \leq b^{11}$;

(D4) for every real U with $100 \log b \leq U \leq 2^\mu$ there is a prime $p \equiv 1$ modulo $M_\omega(P, \mu)^2$ with $U \leq \log p \leq U + \sqrt{\log b}$.

The following objects of Chapter III are attached to P and D. The number $N_1(D) = N_0 \cdot 3^{\lfloor \log_3 \mu \rfloor + 5} \cdot 2^\mu$ and the field $E(D)$, generated over $K(P)$ by a root of unity ς_D of order $N_1(D)$: a CM field, with complex conjugation $y \mapsto \overline{y}$ and ring of integers $\mathcal{O}_{E(D)}$. The set $\mathrm{Pl}(D)$ of its infinite places, of cardinality $f(D)$; each $\tau \in \mathrm{Pl}(D)$ comes with an embedding $E(D) \to \mathbb{C}$, also written τ, and $|y|_\tau = |\tau(y)|$. The root discriminant $\mathrm{rd}_{E(D)}$. The finite places of $E(D)$ are the non-zero prime ideals w of $\mathcal{O}_{E(D)}$; $\mathbb{F}_w$ is the residue field, $\mathrm{N}w$ its cardinality, $\overline{w}$ the conjugate place, and w *lies above* a prime p if $p \in w$. The numbers $k(D) = r + 1 - m$, $t(D) = 5r$, $h_2(D) = r^8$, $h(D) = 2\, h_2(D)$ and $n_j(D) = k(D) + j\,(t(D) + 1)$; the least multiple $a(D)$ of $N_1(D)$ that is at least $x\, b$, and the least multiples $b_1(D)$, $b_2(D)$ of $N_1(D)$ that are at least $a(D)/x$ and $a(D)/x_1$. The *weights*

$$w_{D,j}(\tau) = \begin{cases} b_1(D) + j\, h(D) + h_2(D) & \text{if } \tau \in \mathrm{thick}(D), \\ b_2(D) + j\, h(D) + h_2(D) & \text{otherwise,} \end{cases}$$

and the *nominal weight* $w_D(\tau)$, equal to $a(D)/x$ if $\tau \in \mathrm{thick}(D)$ and to $a(D)/x_1$ otherwise. The number $g(D) = g_0 g_1$. Finally $M_\omega(P, \mu) = (N_0 d)^{\mu+6}$; $\varpi(P, \mu)$ is the purely imaginary generator of the different of $E(D)$ of Chapter III; and $\Omega(P, \mu) = e^{\mathrm{cs}(d)} \cdot 2\pi / \mathrm{rd}_{E(D)}$, where $\mathrm{cs}(d)$ is Euler's constant minus the real part of the logarithmic derivative at 1 of the L-function of the quadratic character of $K(P)$.

Inputs from Chapter III (unit 152, the folder of the data; the notes *The parameters and the CM field* and *Admissible data*). In Setting 2.1:
(I1) If p is a prime with $p \equiv 1$ modulo $N_1(D)\,d$, every finite place of $E(D)$ above p has absolute norm p.
(I2) Every root of unity of $E(D)$ is a power of ς_D; $\prod_{\tau\in\mathrm{Pl}(D)} \tau(y)$ is the norm of y from $E(D)$ to $K(P)$, for every $y \in E(D)$; the cyclotomic polynomial of order $N_1(D)$ is irreducible over $K(P)$.
(I3) $N_1(D)\,d$ divides $M_\omega(P,\mu)$.
(I4) For every $\tau \in \mathrm{Pl}(D)$: $|\varpi(P,\mu)|_\tau = \sqrt{d}\cdot|\Psi'(\varsigma_D)|_\tau$, where Ψ is the cyclotomic polynomial of order $N_1(D)$; and $\Psi(X) = \Psi_0(X^{N_1(D)/N_0})$, where Ψ_0 is the cyclotomic polynomial of order N_0. Moreover $\prod_{\tau\in\mathrm{Pl}(D)} |\varpi(P,\mu)|_\tau = \mathrm{rd}_{E(D)}^{f(D)}$.
(I5) $C(P) \geq d$, $C(P) \geq N_0$, $C(P) \geq |\,\mathrm{cs}(d)|$, and $C(P) \geq \big|\log|\Psi_0'(\varsigma_0)|\big|$ for every primitive root of unity $\varsigma_0 \in \mathbb{C}$ of order N_0.

Characters of $\mathrm{U}(1)$**.** These definitions belong to the background library. Let E be a CM field with a CM type, so that every infinite place τ has an embedding $\tau\colon E \to \mathbb{C}$. The group $\mathrm{U}(1)(\mathbb{A}_E)$ consists of the adeles u of E with $u\overline{u} = 1$; it contains the group $\mathrm{U}(1)(E)$ of the elements of E of norm one to the totally real subfield. A *character of* $\mathrm{U}(1)$ *of* E is a continuous homomorphism from $\mathrm{U}(1)(\mathbb{A}_E)$ to the unit circle that is trivial on $\mathrm{U}(1)(E)$. Such a character ν has *weight* $\mathbf{e} = (\mathbf{e}(\tau))_\tau$, a family of integers, and *tame part* $\psi = (\psi_w)_w$, a family of multiplicative characters ψ_w of the residue fields $\mathbb{F}_w$, if ψ_w is trivial for all but finitely many w and

$$\nu(u) = \prod_\tau u_\tau^{\mathbf{e}(\tau)} \cdot \prod_w \psi_w(u_w \bmod w)$$

for every $u \in \mathrm{U}(1)(\mathbb{A}_E)$ whose finite part is integral; here $u_\tau \in \mathbb{C}$ is the component of u at τ.

Inputs from the background library. Let E be a CM field with a CM type.
(I6) *Existence* (unit 104). Let $\mathbf{e}$ be a family of integers indexed by the infinite places and ψ a family of characters of the residue fields, trivial outside a finite set Σ of finite places. If $\prod_\tau \tau(u)^{\mathbf{e}(\tau)} \cdot \prod_{w\in\Sigma} \psi_w(u \bmod w) = 1$ for every integer u of E with $u\overline{u} = 1$, then there is a character of $\mathrm{U}(1)$ of E of weight $\mathbf{e}$ and tame part ψ. *Status.* The statement is of the type of the existence of algebraic Hecke characters with prescribed infinity type, for which the catalogue cites A. Weil [W] and A. Raghuram [R]. It records the verdict of its second reading: the cited existence result, for characters of the full idele class group, has a different domain and a different compatibility condition, and the existence theorem of [R] prescribes the pure infinity type only. So (I6) is not established as a special case of the cited results; the relation is unresolved, and (I6) is used here as the library proves it.
(I7) *Products* (unit 104). If ν, ν' have weights $\mathbf{e}$, $\mathbf{e}'$ and tame parts ψ, ψ', then $\nu\nu'$ has weight $\mathbf{e}+\mathbf{e}'$ and tame part $\psi\psi'$, and ν^y has weight $y\,\mathbf{e}$ and tame part ψ^y for every integer y.
(I8) *The splitting character.* If E carries Weil data, with splitting character υ restricted to $\mathrm{U}(1)(\mathbb{A}_E)$, then υ^y has the constant weight y and trivial tame part, for every integer y. The field $E(D)$ of Setting 2.1 carries Weil data (Chapter III).

3 Chosen places and their residue characters

Definition 3.1 (chosen places)**.** In Setting 2.1, let P be parameters and D admissible data for P.

(a) $\bar{\pi}_g(D)$ is the complex conjugate of the image of π_g in the ring of integers of $E(D)$.

(b) A finite place w of $E(D)$ is a *chosen place of* D, in symbols $w \in \mathrm{Ch}(D)$, if $\bar{\pi}_g(D) \in w$; otherwise we write $w \notin \mathrm{Ch}(D)$.

(c) For $i \in \{0,1\}$, $\mathrm{Ch}_i(D)$ is the set of the finite places w of $E(D)$ with $\bar{\pi}_g(D) \in w$ and $g_i \in w$: the chosen places above g_i.

(d) For a pair $x = (i, w)$ with $i \in \{0,1\}$ and $w \in \mathrm{Ch}_i(D)$, the place $\mathrm{pl}_D(x)$ is w.

LEAN `Data.piGBar` · `Data.IsChosen` · `Data.ChosenPlace` · `Data.chosen`

Lemma 3.2. *In Setting 2.1, let P be parameters, D admissible data for P, $i \in \{0,1\}$ and w a finite place of $E(D)$.*

(i) $\bar{\pi}_g(D) \cdot \overline{\bar{\pi}_g(D)} = g(D)$*; $\pi_g \neq 0$ and $\bar{\pi}_g(D) \neq 0$.*

(ii) There is a natural number c, prime to g_i, with $\bar{\pi}_g(D) \cdot \overline{\bar{\pi}_g(D)} = g_i\, c$.

(iii) $w \in \mathrm{Ch}(D)$ holds if and only if, for some $i \in \{0,1\}$, both $w \in \mathrm{Ch}(D)$ and $g_i \in w$ hold.

(iv) If w lies above g_i, then $\mathrm{N}w = g_i$.

(v) The set of the chosen places of D is finite; hence so are $\mathrm{Ch}_0(D)$ and $\mathrm{Ch}_1(D)$.

Proof. (i) The product is the image of $\overline{\pi_g}\,\pi_g = g_0 g_1$, and $g_0 g_1 \neq 0$. (ii) Take $c = g_{1-i}$; the primes g_0 and g_1 are distinct. (iii) If $\bar{\pi}_g(D) \in w$ then $g_0 g_1 \in w$ by (i), and w is a prime ideal. (iv) This is (I1), by (D3). (v) A non-zero integer of $E(D)$ lies in finitely many prime ideals. □

4 The characters of the data

Proof of Theorem B(i). Put $\mathbf{e}(\tau) = -c\,w_{D,0}(\tau)$ and $\psi_w = \omega_{D,w}^{n}$. By Lemma 3.5(ii) and Lemma 3.2(v), ψ is trivial outside the finite set Σ of the chosen places, so by (I6) it suffices to show

$$\prod_{\tau \in \mathrm{Pl}(D)} \tau(u)^{-c\,w_{D,0}(\tau)} \cdot \prod_{w \in \Sigma} \omega_{D,w}(u \bmod w)^{n} = 1 \tag{1}$$

for every integer u of $E(D)$ with $u\overline{u} = 1$. Such a u is an algebraic integer all of whose conjugates have absolute value 1, since complex conjugation commutes with every embedding of a CM field; so u is a root of unity (Kronecker), and $u = \varsigma_D^{q}$ for some natural number q by (I2). By Setting 2.1, $w_{D,0}(\tau) - h_2(D)$ is $b_1(D)$ or $b_2(D)$, a multiple of $N_1(D)$; so $\tau(u)^{w_{D,0}(\tau)} = \tau(u)^{h_2(D)}$, and the first product in (1) is

$$\Big(\prod_{\tau \in \mathrm{Pl}(D)} \tau(\varsigma_D)\Big)^{-c\,q\,h_2(D)}.$$

By (I2) the product in brackets is the norm of ς_D to $K(P)$, and the minimal polynomial of ς_D over $K(P)$ is the cyclotomic polynomial Ψ of order $N_1(D)$. Its degree is even and $\Psi(0) = 1$, because $N_1(D) > 2$; so the norm is 1. For the second product, let $w \in \Sigma$. Then $\omega_{D,w} = T_w^{M_\omega(P,\mu)}$, and $\varsigma_D^{M_\omega(P,\mu)} = 1$ because $N_1(D)$ divides $M_\omega(P,\mu)$ by (I3); hence $\omega_{D,w}(\varsigma_D \bmod w) = T_w(\varsigma_D^{M_\omega(P,\mu)} \bmod w) = 1$. This proves (1). □

Definition 4.1 (the three characters)**.** In Setting 2.1, let D be admissible data.

(a) $\mu_D^{\flat}$ is a chosen character of U(1) of $E(D)$ of weight $\tau \mapsto -w_{D,0}(\tau)$ and trivial tame part (Theorem B(i) with $c = 1$, $n = 0$).

(b) χ_D° is a chosen character of U(1) of $E(D)$ of weight 0 and tame part $\omega_{D,\bullet}$ (Theorem B(i) with $c = 0$, $n = 1$).

(c) For a natural number j, $\mu_{D,j}^{0} = \mu_D^{\flat} \cdot \left(\upsilon^{-h(D)}\,\chi_D^{\circ}\right)^{j}$, where υ is the splitting character of the Weil data of $E(D)$, restricted to U(1).

Lemma 4.2. *In Setting 2.1, let P be parameters and D admissible data for P. The character $\mu_D^{\flat}$ has weight $\tau \mapsto -w_{D,0}(\tau)$ and trivial tame part, and χ_D° has weight 0 and tame part $(\omega_{D,w})_w$.*

Proof. By the choices of Definition 4.1, since $\omega_{D,w}^{0} = 1$ and $\omega_{D,w}^{1} = \omega_{D,w}$. □

LEAN `Data.muFlat_hasWeight` · `Data.chi_hasWeight`

Proof of Theorem B(ii) and (iii). (ii) By (I8) the character $\upsilon^{-h(D)}$ has weight $-h(D)$ and trivial tame part. By Lemma 4.2 and (I7), $\upsilon^{-h(D)}\chi_D^{\circ}$ has weight $-h(D)$ and

tame part $\omega_{D,\bullet}$, its j-th power has weight $-j\,h(D)$ and tame part $(\omega_{D,w}^{j})_w$, and $\mu_{D,j}^{0}$ has weight $-w_{D,0}(\tau)-j\,h(D)=-w_{D,j}(\tau)$ and the same tame part. (iii) By Definition 6.2, $\mu_{D,j}(\vartheta)=\mu_{D,j}^{0}\cdot\vartheta$ and ϑ has weight 0 and tame part ψ_ϑ; apply (ii) and (I7). □

Definition 4.3 (pairs)**.** In Setting 2.1, let D be admissible data. The set $\mathrm{Pair}(D)$ of the *pairs* of D consists of the quadruples $(\nu,\mathbf{c},\psi,z)$ of a character ν of $\mathrm{U}(1)$ of $E(D)$, a family $\mathbf{c}=(\mathbf{c}(\tau))_{\tau\in\mathrm{Pl}(D)}$ of natural numbers, a family ψ of characters of the residue fields and a natural number z such that: ν has weight $\tau\mapsto-\mathbf{c}(\tau)$ and tame part ψ; $\psi_w=1$ for every finite place w that is not a chosen place of D; $1\le z\le t(D)$; and $z\le\mathbf{c}(\tau)\le 4b$ for every τ.

LEAN Data.Pair

5 The level

Lemma 5.1 (sizes)**.** *In Setting 2.1, let P be parameters and D admissible data for P. Then*

(i) $x^{10}\le|\varpi(P,\mu)|_\tau\le x^{12}$ *for every infinite place τ of $E(D)$;*

(ii) $x^{10}\le\mathrm{rd}_{E(D)}\le x^{12}$*;*

(iii) $x^{-13}\le\Omega(P,\mu)\le 1$.

Proof. (i) By (I4), $\Psi'(\varsigma_D)=M_0\,\varsigma_D^{M_0-1}\,\Psi_0'(\varsigma_D^{M_0})$ with $M_0=N_1(D)/N_0$, and $\varsigma_D^{M_0}$ is a primitive root of unity of order N_0; so

$$\log|\varpi(P,\mu)|_\tau=\tfrac12\log d+\log M_0+\log\bigl|\Psi_0'(\varsigma_0)\bigr|$$

for a primitive root of unity $\varsigma_0\in\mathbb{C}$ of order N_0. Here

$$\log M_0=(\lfloor\log_3\mu\rfloor+5)\log 3+\mu\log 2.$$

By (D2), $2^\mu=m^{22}$ lies between x^{11} and $2^{22}x^{11}$, and

$$1\le 3^{\lfloor\log_3\mu\rfloor+5}\le 243\,\mu\le 7776\log x.$$

By (I5) the other two terms have absolute value at most $2\,C(P)$, and $10^{14}\,C(P)\le\log x$ by (D1). Hence

$$11\log x-2\,C(P)\le\log|\varpi(P,\mu)|_\tau\le 11\log x+22\log 2+\log(7776\log x)+2\,C(P),$$

which lies between $10\log x$ and $12\log x$. (ii) By (I4), $\mathrm{rd}_{E(D)}$ is the geometric mean of the numbers $|\varpi(P,\mu)|_\tau$; apply (i). (iii) By (I5), $e^{-C(P)}\le e^{\mathrm{cs}(d)}\le e^{C(P)}$; apply (ii) and (D1). □

LEAN Data.hasLogBound_varpi · Data.hasLogBound_rootDisc

In the formal text these bounds are *instances*: facts that Lean's search for comparisons of sizes uses without being named. (iii) is such an instance without a name.

Definition 5.2 (the target)**.** In Setting 2.1, let D be admissible data. Then

$$\mathrm{tar}(D)=m\cdot\frac{1}{f(D)}\sum_{\tau\in\mathrm{Pl}(D)}\log w_D(\tau)+(m-1)\cdot\log\frac{g(D)\cdot\mathrm{rd}_{E(D)}}{2\pi}-\frac{15}{2}\log b.$$

LEAN Data.logLevelTarget

Proof of Theorem A(i). By Setting 2.1, $x\,b \le a(D) < x\,b + N_1(D)$, and $N_1(D) \le C(P)\cdot 243\,\mu\cdot 2^{22}x^{11} \le b$ by (I5), (D2) and (D1). So $b \le a(D)/x \le 2b$ and $1 \le x\,b/x_1 \le a(D)/x_1 \le 2b$, whence $0 \le \log w_D(\tau) \le 2\log b$ for every τ. By (D3), $b^{20} \le g(D) \le b^{22}$; with Lemma 5.1(ii) and $2\pi \le x^{10}$, $x^{12} \le b^5$, this gives $b^2 \le g(D)\ \mathrm{rd}_{E(D)}/(2\pi) \le b^{27}$. Therefore

$$(2m - \tfrac{19}{2})\log b \ \le\ \tau\mathrm{ar}(D) \ \le\ (2m + 27(m-1))\log b,$$

and $m \ge 10$ by (D2) and (D1). □

Definition 5.3 (the level)**.** In Setting 2.1, let D be admissible data. By Theorem A(i), (D1) and (D2), $100\log b \le \tau\mathrm{ar}(D) \le 29\,m\log b \le m^{22} = 2^{\mu}$. The *level* $N(D)$ is a chosen prime number with $N(D) \equiv 1$ modulo $M_\omega(P,\mu)^2$ and $\tau\mathrm{ar}(D) \le \log N(D) \le \tau\mathrm{ar}(D) + \sqrt{\log b}$; one exists by (D4), applied to $U = \tau\mathrm{ar}(D)$.

LEAN Data.N

Proof of Theorem A(ii) and (iii). (ii) $N(D)$ is prime and lies in the window by its choice. By (I3), $N_1(D)\,d$ divides $M_\omega(P,\mu)$, hence $M_\omega(P,\mu)^2$, so $N(D) \equiv 1$ modulo $N_1(D)\,d$. The last two inequalities follow from (i) and $\sqrt{\log b} \le \log b \le m\log b$.

(iii) Since 16 divides N_0 and N_0 divides $N_1(D)$, (ii) gives $N(D) \equiv 1$ modulo 4. By Fermat's theorem on sums of two squares there are integers y, y' with $y^2 + y'^2 = N(D)$. The element $\mathrm{i} = \varsigma_D^{N_1(D)/4}$ of $\mathcal{O}_{E(D)}$ has $\mathrm{i}^2 = -1$, and $\bar{\mathrm{i}} = \mathrm{i}^{-1} = -\mathrm{i}$ because complex conjugation inverts roots of unity. So $\pi = y + y'\,\mathrm{i}$ has $\pi\,\overline{\pi} = y^2 + y'^2 = N(D)$. The second statement is the choice of Definition 5.4. □

Definition 5.4. In Setting 2.1, let D be admissible data. Then $\pi_N(D)$ is a chosen integer π of $E(D)$ with $\pi\,\overline{\pi} = N(D)$ (Theorem A(iii)).

LEAN Data.π

Remark 5.5. Three more facts are recorded in the formal text as instances without names: $N(D)$ is prime; $\sqrt{x}\,\log b \le \log N(D) \le e^{32}\sqrt{x}\,\log b$; and $N(D) \ge b^{101}$. They follow from Theorem A(ii) and $\sqrt{x} \le m \le 2\sqrt{x}$, $m \ge 101$. By (I1) and Theorem A(ii), every finite place of $E(D)$ above $N(D)$ has absolute norm $N(D)$.

6 Tame characters and twists

Definition 6.1 (tame characters, twists)**.** In Setting 2.1, let P be parameters and D admissible data for P.

(a) The set $\mathrm{Tame}(D)$ of the *tame characters of* D consists of the triples of a character of $\mathrm{U}(1)$ of $E(D)$, a finite set Q of finite places of $E(D)$ and a family ψ of characters of the residue fields, such that: the character has weight 0 and tame part ψ; $\psi_w = 1$ for every $w \notin Q$; $\overline{w} \notin Q$ for every $w \in Q$; and $g(D)\cdot N(D)$ is prime to $\prod_{w\in Q} \mathrm{N}w$. We write ϑ for a tame character and for its character of $\mathrm{U}(1)$, $Q(\vartheta)$ for its set and $\psi_\vartheta = (\psi_{\vartheta,w})_w$ for its family.

(b) For a tame character ϑ of D, $\mathrm{n}(\vartheta) = \prod_{w\in Q(\vartheta)} \mathrm{N}w$.

(c) The set $\mathrm{Tw}(D)$ of the *twists of* D consists of the tame characters $\vartheta \in \mathrm{Tame}(D)$ with $\psi_{\vartheta,w} \neq 1$ for every $w \in Q(\vartheta)$.

(d) The *trivial tame character* 1_D of D is the trivial character with $Q(1_D) = \emptyset$ and trivial family; it is a twist of D.

LEAN `Data.TameChar` · `Data.TameChar.levelNorm` · `Data.Twist` · `Data.TameChar.one`

A tame character may mark a place: its set $Q(\vartheta)$ may contain places w with $\psi_{\vartheta,w} = 1$. Non-triviality at every marked place is what a twist adds; so for a twist, and only then, $Q(\vartheta)$ is exactly the set of the places where the tame part is not trivial. The formal text makes the trivial twist the unit element 1 of the type of twists and lets a twist be used as a tame character (two instances without names). The m-fold twists of the overview are the twists ϑ of D such that $\psi_{\vartheta,w}^n \neq 1$ for all $w \in Q(\vartheta)$ and $1 \leq n \leq m$; they, and the power ϑ^n of a tame character (the same set $Q(\vartheta)$, the family ψ_ϑ^n), are defined in Chapter VII (unit 147).

Definition 6.2 (characters of the lifts)**.** In Setting 2.1, let D be admissible data, ϑ a tame character of D and j a natural number.

(a) $\mu_{D,j}(\vartheta) = \mu_{D,j}^0 \cdot \vartheta$, a character of $\mathrm{U}(1)$ of $E(D)$.

(b) $\psi_{D,j}(\vartheta)$ is the family $\left(\omega_{D,w}^j \cdot \psi_{\vartheta,w}\right)_w$ of characters of the residue fields.

(c) $\mathrm{Lf}(D)$ is the set $\{1, \dots, m\}$, the indices of the lifts.

LEAN `Data.liftChar` · `Data.liftTamePart` · `Data.LiftIndex`

7 Index sets

For a natural number q we write $[q] = \{0, \dots, q-1\}$, and $\{*\}$ for a set with one element.

Definition 7.1 (blocks)**.** Let S, T be sets and j a natural number.

(a) $\mathrm{Bl}_j(S,T)$ is defined by recursion: $\mathrm{Bl}_0(S,T) = S$ and $\mathrm{Bl}_{j+1}(S,T) = \mathrm{Bl}_j(S,T) \sqcup T$. It is the disjoint union of S and j copies of T.

(b) $\mathrm{in}_j \colon S \to \mathrm{Bl}_j(S,T)$ is the inclusion of the first block.

(c) For a set α and a bijection $\nu \colon S \to \alpha$, $\mathrm{eq}_j(\nu) \colon \mathrm{Bl}_j(S,T) \to \alpha \sqcup ([j] \times T)$ is a bijection: ν for $j = 0$, and for $j+1$ a chosen bijection, which exists because both sides have the cardinality of $\alpha \sqcup ([j] \times T) \sqcup T$.

LEAN `BlockIndex` · `BlockIndex.firstBlock` · `BlockIndex.equivSum`

Lemma 7.2. *Let S, T be finite sets and j a natural number. Then $\mathrm{Bl}_j(S,T)$ is finite, with $|S| + j\,|T|$ elements.*

Proof. By induction on j; or by the bijection $\mathrm{eq}_j(\nu)$ for the identity ν of S. □

LEAN `instFintypeYT` · `BlockIndex.card`

Definition 7.3 (the index sets of the data)**.** In Setting 2.1, let D be admissible data and j a natural number.

(a) $\varrho(D) = \lfloor m/2 \rfloor - 1$, or 0 if this is negative.

(b) $\underline{X}_j^\circ(D) = [n_j(D) - 1]$.

(c) $\underline{X}_j(D) = \underline{X}^{\circ}_j(D) \sqcup \{*\}$: the basis index set of the standard definite hermitian space $X_j(D)$ of rank $n_j(D)$, the point $*$ indexing the last basis vector.

(d) $\mathfrak{s}(D)$ is the *shape* consisting of the number $\varrho(D)$, the index set $\underline{X}_0(D)$ and its element $*$.

(e) $\underline{R}(D) = [\varrho(D)] \sqcup (\underline{X}_0(D) \sqcup \{\diamond\}) \sqcup [\varrho(D)]$, the index set of the shape $\mathfrak{s}(D)$: indices of $\varrho(D)$ isotropic vectors, of $\underline{X}_0(D)$, of one further vector, and of $\varrho(D)$ dual isotropic vectors. The element $\diamond$ indexes the further vector, the middle vector of the shape; it is not the point $*$, which is an element of $\underline{X}_0(D)$.

(f) $\underline{Y}_j(D) = \mathrm{Bl}_j(\underline{R}(D), [t(D)])$: the basis index set of the hermitian space $Y_j(D)$.

LEAN Data.ϱ · Data.InitIndex · Data.X · Data.shape · Data.RowIndex · Data.Y

Lemma 7.4. *In Setting 2.1, let P be parameters and D admissible data for P. Then $m = 2\,\varrho(D) + 2$, the set $\underline{R}(D)$ has exactly r elements, and $\underline{Y}_j(D)$ has $r + j\,t(D)$ elements for every natural number j.*

Proof. By (D2), m is even and at least 2, so $\varrho(D) = m/2 - 1$; and $m \le 2\sqrt{x} \le x^5 \le r$, so $k(D) = r + 1 - m \ge 1$ and $\underline{X}_0(D)$ has $n_0(D) = k(D)$ elements. Hence

$$|\underline{R}(D)| = 2\,\varrho(D) + k(D) + 1 = (m-2) + (r+1-m) + 1 = r.$$

The last statement is Lemma 7.2. □

LEAN Data.card_rowIndex

The formal text adds an instance without a name: a bound for the size of r is also one for $|\underline{R}(D)|$. The identity $m = 2\,\varrho(D) + 2$ is stated there in Chapter VII (unit 140).

Definition 7.5 (numbering, row parameter, signs)**.** In Setting 2.1, let D be admissible data.

(a) $\mathrm{num}_D \colon \underline{R}(D) \to [r]$ is a chosen bijection (Lemma 7.4).

(b) For an infinite place τ of $E(D)$ and a natural number i, the entry i of the *row parameter* is

$$\mathrm{par}_{D,\tau}(i) = \begin{cases} k(D)/2 - 1 - i & \text{if } i+1 < k(D), \\ h_2(D) - w_{D,i+2-k(D)}(\tau) & \text{if } i+1 \ge k(D). \end{cases}$$

(c) For an infinite place τ and $i \in \underline{R}(D)$: $\mathrm{par}^W_{D,\tau}(i) = 2\,\mathrm{par}_{D,\tau}(\mathrm{num}_D(i))$.

(d) For a natural number j and $i \in \underline{R}(D)$: $\mathrm{sg}^W_{D,j}(i) = -1$ if $\mathrm{num}_D(i) \ge k(D) + j - 1$, and $\mathrm{sg}^W_{D,j}(i) = +1$ otherwise.

LEAN Data.basisNumber · Data.rowParameter · Data.paramW · Data.signsW

The number $k(D)$ is even, since r is odd and m even. For $i = k(D) - 1, \dots, r - 1$ the second case gives $-(w_{D,q}(\tau) - h_2(D))$ with $q = i + 2 - k(D) \in \{1, \dots, m\}$. So the row parameter consists of the $k(D) - 1$ numbers $k(D)/2 - 1, \dots, 1 - k(D)/2$, followed by m entries given by the weights of the m lifts; $\mathrm{par}^W_{D,\tau}(\cdot)$ is the doubled parameter of the forms on $Y_0(D)$ and on the spaces W_j of signs $\mathrm{sg}^W_{D,j}(\cdot)$ of Chapter VII.

Definition 7.6 (entry signs)**.** For natural numbers o, j, a the sign $\mathrm{sg}(o, j, a) \in \{\pm 1\}$ is defined by recursion on o:

$$\mathrm{sg}(o+1, 0, a) = -\,\mathrm{sg}(o, 0, a),$$
$$\mathrm{sg}(o, j, a) = (-1)^{\,o + a + \min(\max(a-o, 0),\, j)} \quad \text{in all other cases.}$$

The second formula holds in the first case as well, since $\min(\max(a-o,0),0)=0$.

LEAN `Data.entrySign`

Lemma 7.7. *Let j be a natural number and y an integer. Then the number that is $y-1$ if j is odd and y if j is even equals $y-(j \bmod 2)$.*

Proof. $j \bmod 2$ is 1 or 0 accordingly. □

LEAN `Data.ite_odd_eq_sub_emod`

Definition 7.8 (the finite group and its idempotent)**.** In Setting 2.1, let D be admissible data.

(a) $\mathsf{G}(D)=\prod_x \mathrm{GL}_{\underline{R}(D)}(\mathbb{F}_{\mathrm{pl}_D(x)})$, the product over the pairs $x=(i,w)$ with $i\in\{0,1\}$ and $w\in \mathrm{Ch}_i(D)$: a finite group, the product of the groups GL_r of the residue fields of the chosen places.

(b) $\mathrm{Good}(D)$ is the finite set of the families $(c_x)_x$ of monic polynomials c_x of degree r over $\mathbb{F}_{\mathrm{pl}_D(x)}$ such that, for each $i\in\{0,1\}$, the tuple $(c_{(i,w)})_{w\in\mathrm{Ch}_i(D)}$ is *good* for $M_\omega(P,\mu)$ and r: every $c_{(i,w)}$ is squarefree with non-zero constant term and has no root y in $\mathbb{F}_w$ with $y^{M_\omega(P,\mu)}=1$, and at least one $c_{(i,w)}$ is irreducible with a root of multiplicative order $(\mathrm{N}w)^r-1$ in an algebraic closure of $\mathbb{F}_w$.

(c) $e_0(D)=\sum_{c\in\mathrm{Good}(D)}\bigotimes_x e_{c_x}$ in the group algebra $\mathbb{C}[\mathsf{G}(D)]$, where e_{c_x} is the idempotent of Green's character with the label c_x in the group algebra of $\mathrm{GL}_{\underline{R}(D)}(\mathbb{F}_{\mathrm{pl}_D(x)})$.

LEAN `Data.G` · `Data.goodTupleFamilies` · `Data.e₀`

Good tuples and the idempotents e_c belong to Chapter VII (unit 140, the note *Primitive labels of general linear groups over finite fields*) and to the background library; there $e_0(D)$ is shown to be a central idempotent, and the rows of the overview are its image on the forms of principal level on $Y_0(D)$.

8 The branching pairing

In this section E is a CM field with a CM type, and weights and their Harish-Chandra parameters are as before Theorem C. We recall the objects of the background library that the theorem names.

Representations. For a weight (κ,e) and a finite index set n, the vectors *of weight κ in rank $|n|$* over a commutative ring R are the coordinate vectors, in the basis of semistandard fillings, of the product over the infinite places τ of the Weyl modules of GL_n whose Young diagram has $\kappa_\tau(h)$ columns of height h, for $0<h<|n|$. On them a family $g=(g_\tau)_\tau$ of matrices in $\mathrm{GL}_n(R)$ acts by $\rho_{\kappa,e}(g)=\prod_\tau \det(g_\tau)^{e_\tau}$ times the Schur matrix of g. For vectors v', v with the same index set, $\langle v',v\rangle=\sum_a v'_a v_a$ is the bilinear dot product, and $\|v\|^2$ is the value at (v,v) of the positive definite hermitian form on complex vectors of weight κ given by the integral Gram matrix of the Weyl lattice. $\mathrm{boxes}(\kappa,N)=\sum_\tau\sum_{h<N} h\,\kappa_\tau(h)$ is the number of boxes. For a ring S with an involution $y\mapsto\overline{y}$, $\mathrm{U}_n(S)$ is the group of the $g\in\mathrm{GL}_n(S)$ with $\overline{g}^{\mathrm{t}}g=1$; for $g\in\mathrm{U}_n(S)$ and $u\in\mathrm{U}_1(S)$, $\mathrm{diag}_\sigma(g,u)\in\mathrm{U}_{n'}(S)$ is the block diagonal matrix with blocks g and u, relabelled by σ; and for ring homomorphisms $f_\tau\colon S\to R$, $f(g)$ is the family $(f_\tau(g))_\tau$, entry by entry.

Forms. A *standard* hermitian space V with index set n has Gram matrix 1 and the standard lattice; its signs are all $+1$. Its adelic unitary group is the product of a compact real group and $\mathrm{U}_n(\mathbb{A}_f)$; $[\mathrm{U}(V)]$ is the quotient by the rational points, with the invariant measure that the background library fixes. An *algebraic form* of weight (κ, e) in rank $|n|$ is a function ϕ on $\mathrm{U}_n(\mathbb{A}_f)$, invariant on the right under an open subgroup, with values in the complex vectors of weight κ in rank $|n|$, such that $\phi(y_0 h) = \rho_{\kappa,e}(y_0)\phi(h)$ for rational points y_0. For a family l that is the doubled Harish-Chandra parameter of (κ, e) and signs $\mathbf{s}$, the function $F_\phi^{l,\mathbf{s}}$ on the adelic group is $(y_\infty, h) \mapsto (v_l^+, \overline{\rho_{\kappa,e}}(y_\infty)^{-1}\phi(h))$, the coefficient of the highest weight vector v_l^+ for the Gram form, where $\overline{\rho_{\kappa,e}}$ is $\rho_{\kappa,e}$ at the complex conjugates of the matrices. A *level* is an open subgroup $\mathcal{K}$ of the stabiliser $\mathcal{K}_0$ of the standard lattice in $\mathrm{U}_n(\mathbb{A}_f)$, and for a function F on $\mathrm{U}_n(\mathbb{A}_f)$, left invariant under the rational points and right invariant under an open subgroup, $\mathrm{mean}_{\mathcal{K}}(F)$ is its integral over the quotient of $\mathrm{U}_n(\mathbb{A}_f)$ by the rational points for the measure that gives $\mathcal{K}$ the volume 1: a finite sum over classes, weighted by inverse orders of stabilisers.

Inputs for Theorem C. Let E, n, n', σ be as in Theorem C, with $|n'| = |n|+1$.
(I9) *Parameters with a gap* (unit 143). If a family $l = (l_\tau)$ of maps $n \to \mathbb{Z}$ has, for every τ, distinct values that are all congruent to $|n|-1$ modulo 2, then l is the doubled Harish-Chandra parameter of some weight $(\kappa^\natural, e^\natural)$.
(I10) *Dual pairing* (unit 101). If l is the doubled Harish-Chandra parameter of $(\kappa^\natural, e^\natural)$ and $-l$ that of (κ', e'), both in rank $|n|$, there is an integer matrix A with: $\langle \rho_{\kappa',e'}(g)v', A\,\rho_{\kappa^\natural,e^\natural}(g)v\rangle = \langle v', Av\rangle$ for all fields R of characteristic 0, all families g in $\mathrm{GL}_n(R)$ and all v', v; for all signs $\mathbf{s}$ and algebraic forms η of weight (κ', e'), $F_\eta^{-l,\mathbf{s}}(y_\infty, h) = \langle \eta(h), A\,\overline{\rho_{\kappa^\natural,e^\natural}}(y_\infty)v_l^+\rangle$; and for every complex vector v of weight $\kappa^\natural$ there is a complex vector v° of weight κ' with $\|v^\circ\| = \|v\|$ and $\langle v', Av\rangle = (v^\circ, v')$ for all v', where $(\cdot,\cdot)$ is the Gram form, conjugate linear in the first variable.
(I11) *Branching* (unit 19; the branching law from $\mathrm{GL}_{|n|+1}$ to $\mathrm{GL}_{|n|}$ with multiplicity one, in an integral form, here in the case $q = 0$ of the formal statement; reference to be confirmed). Let (κ, e) be a weight, and let $\kappa^\uparrow$, $\kappa^\downarrow$ be families of functions $\mathbb{N} \to \mathbb{N}$ with $\kappa^\uparrow + \kappa^\downarrow = \kappa$. Let $(\kappa^\natural, e^\natural)$ be a weight with $\kappa_\tau^\natural(h) = \kappa_\tau^\downarrow(h) + \kappa_\tau^\uparrow(h+1)$ for $0 < h < |n|$ and $e_\tau^\natural = e_\tau + \kappa_\tau^\downarrow(|n|)$. Then there is an integer matrix br, from weight κ in rank $|n'|$ to weight $\kappa^\natural$ in rank $|n|$, such that: over every field R of characteristic 0,

$$\mathrm{br}\cdot\rho_{\kappa,e}(\mathrm{diag}_\sigma(g,u)) = \prod_\tau u_\tau^{\,e_\tau+\sum_{0<h<|n'|}\kappa_\tau^\uparrow(h)}\cdot\rho_{\kappa^\natural,e^\natural}(g)\cdot\mathrm{br}$$

for all families g in $\mathrm{GL}_n(R)$ and u in $R^\times$; $\|\mathrm{br}\,v\| \le (M^M)^3\|v\|$ for all complex v and every natural number $M \ge \mathrm{boxes}(\kappa^\natural, |n|)$; and every complex matrix that intertwines $\rho_{\kappa,e}(\mathrm{diag}_\sigma(g,1))$ with $\rho_{\kappa^\natural,e^\natural}(g)$ for all families g of unitary matrices is a multiple of br.
(I12) *Periods as means* (unit 27; reference to be confirmed). Let V be a standard space with index set n, let br have the last property of (I11), let L' be a linear functional on the complex vectors of weight κ in rank $|n'|$ and $v^\natural$ a complex vector of weight $\kappa^\natural$ in rank $|n|$. Then there is a complex number C such that for every algebraic form ϕ of weight (κ, e) in rank $|n'|$, every automorphic function Φ on the adelic unitary group of V, every $u \in \mathrm{U}_1(\mathbb{A}_f)$, every family $(L_h)_h$ of linear functionals on the complex vectors of weight $\kappa^\natural$, indexed by $h \in \mathrm{U}_n(\mathbb{A}_f)$, and every level $\mathcal{K}$: if $\Phi(y_\infty, h) = L_h(\overline{\rho_{\kappa^\natural,e^\natural}}(y_\infty)v^\natural)$ for all (y_∞, h), then

$$\int_{[\mathrm{U}(V)]}\Phi(y)\cdot L'(\overline{\rho_{\kappa,e}}(\mathrm{diag}_\sigma(y_\infty,1))^{-1}\phi(\mathrm{diag}_\sigma(h,u)))\,dy = \frac{C}{[\mathcal{K}_0:\mathcal{K}]}\cdot\mathrm{mean}_{\mathcal{K}}(h\mapsto L_h(\mathrm{br}\,\phi(\mathrm{diag}_\sigma(h,u)))),$$

where $y = (y_\infty, h)$. The functions $F_\eta^{-l,\mathbf{s}}$ are automorphic (unit 102).

Proof of Theorem C. Since σ is a bijection, $|n'| = |n| + 1$; write $N = |n|$. By the two hypotheses on the signs, all of $\mathbf{s}$, $\mathbf{r}$, $\mathbf{t}$ are 1. Since $-l$ is a doubled Harish-Chandra parameter in rank N, the values of each l_τ are distinct and congruent to $N-1$ modulo 2; by (I9), l is the doubled Harish-Chandra parameter of a weight $(\kappa^\natural, e^\natural)$. For $0 \le p \le N$ and $0 \le q < N$ put

$$\lambda_\tau(p) = e_\tau + \sum_{p<h<N+1}\kappa_\tau(h), \qquad \lambda_\tau^\natural(q) = e_\tau^\natural + \sum_{q<h<N}\kappa_\tau^\natural(h),$$

the highest weights. The values of l'_τ in decreasing order are $2\lambda_\tau(p)+N-2p$, $p=0,\dots,N$, and those of l_τ are $2\lambda^\natural_\tau(q)+N-1-2q$, $q=0,\dots,N-1$.

Interlacing. Fix τ and $q<N$, and count values from 0. Exactly q values of l'_τ exceed its q-th value y; by the hypothesis at this y, at most q values of l_τ exceed it, so the q-th value of l_τ is at most the q-th value of l'_τ. Exactly q values of l_τ exceed its q-th value y; by the hypothesis at this y, at most $q+1$ values of l'_τ exceed it, so the $(q+1)$-st value of l'_τ is at most the q-th value of l_τ. The values of l_τ and of l'_τ have opposite parities, so both inequalities are strict, and in terms of the highest weights they read

$$\lambda_\tau(q+1)\ \le\ \lambda^\natural_\tau(q)\ \le\ \lambda_\tau(q)\qquad(0\le q<N).\tag{2}$$

Put $\delta_\tau(q)=\lambda^\natural_\tau(q)-\lambda_\tau(q+1)$; it is half of the difference of the q-th value of l_τ and the $(q+1)$-st value of l'_τ, rounded down, and $0\le\delta_\tau(q)\le\kappa_\tau(q+1)$ by (2).

The matrix. Let $\kappa^\downarrow_\tau(h)=\delta_\tau(h-1)$ and $\kappa^\uparrow_\tau(h)=\kappa_\tau(h)-\delta_\tau(h-1)$ for $1\le h\le N$, and $\kappa^\downarrow_\tau(h)=0$, $\kappa^\uparrow_\tau(h)=\kappa_\tau(h)$ for the other h. Then $\kappa^\uparrow+\kappa^\downarrow=\kappa$, and

$$\kappa^\downarrow_\tau(h)+\kappa^\uparrow_\tau(h+1)=\lambda^\natural_\tau(h-1)-\lambda^\natural_\tau(h)=\kappa^\natural_\tau(h)\qquad(0<h<N),$$
$$e_\tau+\kappa^\downarrow_\tau(N)=\lambda_\tau(N)+\delta_\tau(N-1)=\lambda^\natural_\tau(N-1)=e^\natural_\tau.$$

So (I11) gives a matrix br, and (I10) a matrix A. Put $B=A\cdot\mathrm{br}$ and

$$N_\tau=e_\tau+\sum_{0<h<N+1}\kappa^\uparrow_\tau(h).$$

(a1) For $g\in\mathrm{U}_n(S)$ and $u\in\mathrm{U}_1(S)$, the intertwining property of br over R, at the families $f(g)$ and $(f_\tau(\det u))_\tau$, and then the invariance of A give

$$\langle\rho_{\kappa',e'}(f(g))v',A\,\mathrm{br}\,\rho_{\kappa,e}(f(\mathrm{diag}_\sigma(g,u)))v\rangle=\prod_\tau f_\tau(\det u)^{N_\tau}\cdot\langle v',A\,\mathrm{br}\,v\rangle.$$

(a2) $|N_\tau|\le|e_\tau|+\sum_{0<h<N+1}\kappa_\tau(h)\le|e_\tau|+\mathrm{boxes}(\kappa,N+1)$.

(a3) By (I10), applied to the vector $\mathrm{br}\,v$, there is v° with $\|v^\circ\|=\|\mathrm{br}\,v\|$ and $\langle v',A\,\mathrm{br}\,v\rangle=(v^\circ,v')$. The Cauchy–Schwarz inequality for the positive definite Gram form and (I11) give $|\langle v',Bv\rangle|\le\|\mathrm{br}\,v\|\,\|v'\|\le(M^M)^3\|v\|\,\|v'\|$, provided $M\ge\mathrm{boxes}(\kappa^\natural,N)$. This holds for $M\ge\mathrm{boxes}(\kappa,N+1)$: counting boxes by rows,

$$\mathrm{boxes}(\kappa^\natural,N)=\sum_\tau\sum_{q<N}(\lambda^\natural_\tau(q)-e^\natural_\tau),\qquad\mathrm{boxes}(\kappa,N+1)=\sum_\tau\sum_{p<N+1}(\lambda_\tau(p)-e_\tau),$$

and $\lambda^\natural_\tau(q)-e^\natural_\tau\le\lambda_\tau(q)-e_\tau$ by (2) and $e^\natural_\tau\ge e_\tau$.

(b) Fix g. Apply (I12) to the standard space, the matrix br, the vector $v^\natural=v^+_l$ and the functional $L'=(v^+_{l'},\overline{\rho_{\kappa,e}}(g)^{-1}\cdot)$; it gives C. For V, η, ϕ, u, $\mathcal{K}$ as in the statement, V is the standard space, $\Phi=F^{-l,\mathrm{s}}_\eta$ is automorphic, and by (I10) it has the form required in (I12) with $L_h=\langle\eta(h),A\cdot\rangle$. The left side of (I12) is then the integral of the theorem, because the value of $F^{l',\mathrm{t}}_\phi$ at $\mathrm{diag}_\sigma(y,(1,u))\cdot(g,1)$ is $L'(\overline{\rho_{\kappa,e}}(\mathrm{diag}_\sigma(y_\infty,1))^{-1}\phi(\mathrm{diag}_\sigma(h,u)))$, and the right side is the mean of $h\mapsto\langle\eta(h),A\,\mathrm{br}\,\phi(\mathrm{diag}_\sigma(h,u))\rangle$. □

9 The grid spaces

Chapter VII compares the chain of lifts with a second chain by moving through two grids of hermitian spaces, the grid V and the grid Z. The file read here only names the objects on the grids; their index sets, signs and parameters are defined in Chapter VII. In this section D is admissible data as in Setting 2.1, and $z \in \{0,1\}$ names a grid: $z = 0$ is the grid V, $z = 1$ the grid Z. (The formal text uses truth values; 1 is *true*.)

Inputs from Chapter VII (units 140 and 147) **and from the background library.** In Setting 2.1:
(I13) *Spaces.* A hermitian space with a point over $E(D)$, with a finite index set and signs on it, is a Gram matrix over $E(D)$ with an adelic frame that brings it to the diagonal matrix of the signs at the infinite places and to 1 at the finite places. Such spaces have orthogonal sums $\oplus$, relabellings along bijections of index sets that carry the signs, and opposites (the Gram matrix and the signs are negated); for signs $\mathbf{s}$ there is the standard signed space $I(\mathbf{s})$. For every natural number j, $Y_j(D)$ is a hermitian space with index set $\underline{Y}_j(D)$ and signs $\mathrm{sgn}^{0,0}_{0,j}(D)$ (unit 140).
(I14) *Index sets, signs, parameters* (unit 147). For $z \in \{0,1\}$ and natural numbers o, i, j: $\underline{\mathcal{V}}^z_{i,j}(D) = \mathrm{Bl}_j(\mathrm{Bl}_i(\mathrm{Bl}_z(\underline{R}(D), \{*\}), [t(D)+z]), [t(D)-z])$, a set with $r + z + i\,(t(D)+z) + j\,(t(D)-z)$ elements; its base indices, those of $\mathrm{Bl}_z(\underline{R}(D), \{*\})$, are numbered by num_D and, for the point, by r. The signs $\mathrm{sgn}^{z,o}_{i,j}(D)$ on it are $\mathrm{sg}(o, j, \max(q+1-k(D), 0))$ at the base index of number q and $+1$ elsewhere. The doubled parameter $\mathrm{gpar}^{z,o}_{i,j}(D,\tau)$, for an infinite place τ, is the integer vector on the same index set with the following entries: $2\,\mathrm{par}_{D,\tau}(q)$ at the base index of number q; $2\,w_{D,l+1}(\tau) + t(D) - 1 - 2a$ at the position $a \in [t(D)+z]$ of the block $l < i$ of the first kind; $t(D) - 1 - 2\,(w_{D,l+1+o}(\tau) + z) - 2a$ at the position $a \in [t(D)-z]$ of the block $l < j$ of the second kind; all raised by 1 if $z = 1$, and lowered by 1 if $z = 0$ and $i+j$ is odd. The weight $\mathrm{gw}_D(c, l, n)$, for $c \in \{0,1\}$, a natural number l and a finite set n, is $\tau \mapsto \lfloor (|n| + 1 - c)/2 \rfloor - w_{D,l+1}(\tau)$. The polynomial $\mathrm{har}_D(o, d, c, l; z; a, b; i, j)$, for $d \in \{0,1\}$, is a chosen joint harmonic for the nodes (a,b) and (i,j) of grid z, the weights $\mathrm{gw}_D(c, l, \cdot)$ and the parameters, negated if $d = 1$. Facts: (i) $\mathrm{sgn}^{1,0}_{0,0}(D)$ is $\mathrm{sgn}^{0,0}_{0,0}(D)$ on $\underline{R}(D)$ and $+1$ at the point; (ii) the number of signs -1 in $\mathrm{sgn}^{z,0}_{i,j}(D)$ is $\lfloor (\max(m-j, 0) + z)/2 \rfloor$; (iii) there are chosen bijections $\Delta_j \colon \underline{\mathcal{V}}^0_{j,j}(D) \sqcup \{*\} \to \underline{\mathcal{V}}^1_{j,j}(D)$, the identity for $j = 0$, such that for $j \le m$ the signs $\mathrm{sgn}^{1,0}_{j,j}(D)$ correspond to $\mathrm{sgn}^{0,0}_{j,j}(D)$ and $(-1)^j$ at the point; (iv) for all z, i, j and τ, the entries of $\mathrm{gpar}^{z,0}_{i,j}(D,\tau)$ are distinct, congruent to $|\underline{\mathcal{V}}^z_{i,j}(D)| - 1$ modulo 2, and two entries at indices of different signs differ by at least $2\,h(D)$; (v) for a step of the grid as in Lemma 9.8, the weights, parameters and signs at its two ends correspond in the sense of the theta correspondence of discrete series parameters; (vi) $t(D)$ is odd.

Inputs from Chapter VII and from the background library, continued. In Setting 2.1:
(I15) *Moduli* (units 140 and 147). For a tame character ϑ of D and a natural number $q \geq 1$, $\mathfrak{m}_D(\vartheta; q)$ is the ideal of $\mathcal{O}_{E(D)}$ that is the q-th power of the product of the chosen places of D, times the product of the places of $Q(\vartheta)$; its prime divisors are the chosen places and the places of $Q(\vartheta)$. For an m-fold twist ϑ: $\mathfrak{m}_D(\vartheta) = \mathfrak{m}_D(\vartheta; b_1(D))$, $\mathfrak{m}_D^{\triangle}(0, \vartheta) = \mathfrak{m}_D(\vartheta; 1)$ and $\mathfrak{m}_D^{\triangle}(1, \vartheta) = \mathfrak{m}_D(1_D; b_1(D))$, which divides $\mathfrak{m}_D(\vartheta)$. For a finite index set n and each of these ideals $\mathfrak{a}$, reduction from the stabiliser $\mathcal{K}_0$ of the standard lattice in $\mathrm{U}_n(\mathbb{A}_f)$ to $\mathrm{GL}_n(\mathcal{O}_{E(D)}/\mathfrak{a})$ is surjective.
(I16) *Kernels and lifts* (background library). For a parameter l and signs $\mathbf{s}$ on a finite index set, the *kernel pair* of $(l, \mathbf{s})$ sends 0 to the product over the infinite places of the discrete series kernels of the parameters l_τ, and 1 to that of $-l$. A pair of functions on the real unitary group is a *conjugate kernel pair* if the two are complex conjugates of each other and each is a cusp kernel of order 0. If, for every τ, the entries of l_τ are distinct, of the right parity, and differ by at least $1000\,|n|^3$ at indices of different signs, then the kernel pair of $(l, \mathbf{s})$ is a conjugate kernel pair. For spaces $\mathcal{S}$, $\mathcal{T}$, characters of $\mathrm{U}(1)$, a polynomial and a function Ψ of matrices modulo an ideal, there are the theta lift from forms on $\mathcal{S}$ to forms on $\mathcal{T}$ and the descent in the other direction, both with the Schwartz function made of the polynomial at the infinite places and of Ψ at the finite places. A family of characters, two kernel pairs, a direction $d \in \{0, 1\}$ and a polynomial form an *edge family* if both pairs are conjugate kernel pairs, the characters have weights independent of the member of the family, and the polynomial is an edge for the real Weil representation between the kernels of index d. If weights, parameters and signs correspond as in (I14)(v), then the kernel pairs, the joint harmonic and any family of characters of these weights form an edge family. *Status.* The catalogue classes the two statements of (I16) as substantial and gives no reference for them: reference to be confirmed. The second rests on the library's statement that, for corresponding parameters, the vector of the Fock model given by the product of the chosen joint harmonics is an edge between the two discrete-series types. For that statement the catalogue cites Ichino [I], Theorem 4.1 and Lemma 7.8, for the compact types, and records the verdict of its second reading: the formal matching condition selects witnesses for a two-sided analytic statement beyond the published joint-type criterion. So the formal statement is not a special case or a weaker form of the cited ones; it goes beyond them, and its relation to the literature is unresolved. It is used here as the library proves it.
(I17) *Determinants* (background library). If a character ν of $\mathrm{U}(1)$ of $E(D)$ has a weight and a tame part ψ that is trivial outside the prime divisors of an ideal $\mathfrak{a}$, then for every finite index set n', all signs $\mathbf{s}$ on n' and every $k \in \mathcal{K}_0 \subseteq \mathrm{U}_{n'}(\mathbb{A}_f)$: the value of ν at the determinant of the adelic point $(1, k)$ is $\prod_{w \mid \mathfrak{a}} \psi_w(\det(k \bmod w))$.

Definition 9.1 (nodes and their spaces)**.** In Setting 2.1, let D be admissible data.

(a) A *node* is a triple $p = (z, a, b)$ of an element $z \in \{0, 1\}$ and natural numbers a, b.

(b) For a node $p = (z, i, j)$: $\underline{\mathcal{V}}_D(p) = \underline{\mathcal{V}}^z_{i,j}(D)$.

(c) For natural numbers o, i, j and $z \in \{0, 1\}$, the hermitian space $\mathcal{V}^z_{i,j}[o](D)$ has index set $\underline{\mathcal{V}}^z_{i,j}(D)$ and signs $\mathrm{sgn}^{z,o}_{i,j}(D)$. It is: $Y_0(D) \oplus I(+1)$ for $(o, z, i, j) = (0, 1, 0, 0)$, where $I(+1)$ is the standard line of sign $+1$; $Y_j(D)$ for $(o, z, i) = (0, 0, 0)$; the opposite of $\mathcal{V}^z_{0,0}[o-1](D)$ for $o \geq 1$ and $i = j = 0$; and the standard signed space $I(\mathrm{sgn}^{z,o}_{i,j}(D))$ in all other cases.

LEAN Data.Node · Data.NodeIndex · Data.gridSpace

The first case has the right signs by (I14)(i), and the third because $\mathrm{sg}(o, 0, a) = -\mathrm{sg}(o-1, 0, a)$; this is why Definition 7.6 begins with that equation.

Definition 9.2 (forms on the grids)**.** In Setting 2.1, let D be admissible data, $z \in \{0, 1\}$ and i, j, a, b natural numbers.

(a) $\ker^z_{i,j}(D)$ is the kernel pair of the parameter $\tau \mapsto \mathrm{gpar}^{z,0}_{i,j}(D, \tau)$ and the signs $\mathrm{sgn}^{z,0}_{i,j}(D)$ (Input (I16)).

(b) $\mathcal{F}^z_{a,b}(D)$ is the space of the forms on the unitary group of $\mathcal{V}^z_{a,b}[0](D)$ whose type is the kernel of index 1 of $\ker^z_{a,b}(D)$, that of the negated parameter; it carries the Petersson product.

(c) $\mathcal{F}^{\mathrm{lev}}_i(D)$ is the subspace of $\mathcal{F}^1_{0,i}(D)$ of the forms fixed by the principal level of the integer $\bar{\pi}_g(D)^{\,b_1(D)}$.

LEAN Data.gridKernel · Data.GridForm · Data.gridLevelForms

Definition 9.3 (characters on the grids)**.** In Setting 2.1, let D be admissible data, ϑ an m-fold twist of D, $c \in \{0, 1\}$, l a natural number and n a finite index set.

(a) the character $\mu^{\mathrm{gr}}_{D,l}(\vartheta; c, n)$ is given by

$$\mu^{\mathrm{gr}}_{D,l}(\vartheta; c, n) = \begin{cases} \mu_{D,l+1}(\vartheta^{l+1}) \cdot \upsilon^{\lfloor |n|/2 \rfloor} & \text{if } c = 1, \\ \mu_{D,l+1}(1_D) \cdot \upsilon^{\lfloor (|n|+1)/2 \rfloor} & \text{if } c = 0. \end{cases}$$

(b) $\psi^{\mathrm{gr}}_{D,l}(\vartheta; c) = \psi_{D,l+1}(\vartheta^{l+1})$ if $c = 1$, and $\psi^{\mathrm{gr}}_{D,l}(\vartheta; c) = \psi_{D,l+1}(1_D)$ if $c = 0$.

LEAN Data.gridChar · Data.gridTamePart

Definition 9.4 (levels on the grids)**.** In Setting 2.1, let D be admissible data, ϑ an m-fold twist of D, $z \in \{0, 1\}$ and a, b natural numbers.

(a) $\mathrm{to}_D(z, \vartheta, b)$ is the order of the group $\mathrm{GL}_{\underline{\mathcal{V}}^z_{0,b}(D)}(\mathcal{O}_{E(D)}/\mathfrak{m}^{\triangle}_D(z, \vartheta))$.

(b) For a node $p = (z, a, b)$, $\mathcal{K}_D(\vartheta; p)$ is the following subgroup of the group $\mathrm{GL}_{\underline{\mathcal{V}}_D(p)}(\mathcal{O}_{E(D)}/\mathfrak{m}_D(\vartheta))$: it is trivial if $z = 0$ and $a = 0$, and otherwise it is the kernel of reduction to $\mathrm{GL}_{\underline{\mathcal{V}}_D(p)}(\mathcal{O}_{E(D)}/\mathfrak{m}^{\triangle}_D(1, \vartheta))$.

(c) $\mathrm{ix}_D(\vartheta; z, a, b)$ is the index of $\mathcal{K}_D(\vartheta; (z, a, b))$ in that group, as a complex number.

LEAN Data.triangleOrder · Data.nodeLevel · Data.levelIndex

Definition 9.5 (moves on the grids)**.** In Setting 2.1, let D be admissible data, ϑ an m-fold twist of D, $z \in \{0, 1\}$ and a, b natural numbers. In each case F is a form in the source of the map.

(a) $\mathrm{desc}^{z}_{D,b}(\vartheta)(\,\cdot\,)\colon \mathcal{F}^{z}_{0,b+1}(D) \to \mathcal{F}^{z}_{0,b}(D)$ is $\mathrm{to}_D(z,\vartheta,b)$ times the descent (Input (I16)) from the space $\mathcal{V}^{z}_{0,b+1}[0](D)$ to the space $\mathcal{V}^{z}_{0,b}[0](D)$, formed with the characters $n \mapsto \mu^{\mathrm{gr}}_{D,b}(\vartheta; 1-z, n)$, with the polynomial

$$\mathrm{har}_D(0,0,1-z,b;z;0,b;0,b+1)$$

and, at the finite places, with the indicator of the matrix of the inclusion of $\underline{\mathcal{V}}^{z}_{0,b}(D)$ into $\underline{\mathcal{V}}^{z}_{0,b+1}(D)$ modulo $\mathfrak{m}^{\triangle}_D(z,\vartheta)$; we write $\mathrm{desc}^{z}_{D,b}(\vartheta)(F)$ for its value at F.

(b) $\iota^{+,z}_{D,b}(\vartheta)(\,\cdot\,)\colon \mathcal{F}^{z}_{0,m}(D) \to \mathcal{F}^{z}_{0,b}(D)$ is defined by descending recursion: it is the identity for $b = m$, zero for $b > m$, and for $b < m$

$$\iota^{+,z}_{D,b}(\vartheta)(F) = \mathrm{desc}^{z}_{D,b}(\vartheta)(\iota^{+,z}_{D,b+1}(\vartheta)(F)).$$

(c) For a matrix y over $\mathcal{O}_{E(D)}/\mathfrak{m}_D(\vartheta)$ with rows indexed by $\underline{\mathcal{V}}^{z}_{a,b+1}(D)$ and columns by $\underline{\mathcal{V}}^{z}_{a,b}(D)$, $\mathrm{desc}_D[y](\,\cdot\,)\colon \mathcal{F}^{z}_{a,b+1}(D) \to \mathcal{F}^{z}_{a,b}(D)$ is the descent with the characters $n \mapsto \mu^{\mathrm{gr}}_{D,b}(\vartheta; 1-z, n)$, the polynomial $\mathrm{har}_D(0,0,1-z,b;z;a,b;a,b+1)$ and the indicator of y modulo $\mathfrak{m}_D(\vartheta)$.

(d) For a matrix y over $\mathcal{O}_{E(D)}/\mathfrak{m}_D(\vartheta)$ with rows indexed by $\underline{\mathcal{V}}^{z}_{a+1,b}(D)$ and columns by $\underline{\mathcal{V}}^{z}_{a,b}(D)$, $\mathrm{lift}_D[y](\,\cdot\,)\colon \mathcal{F}^{z}_{a,b}(D) \to \mathcal{F}^{z}_{a+1,b}(D)$ is the lift with the characters $n \mapsto \mu^{\mathrm{gr}}_{D,a}(\vartheta; z, n)$, the polynomial $\mathrm{har}_D(0,1,z,a;z;a,b;a{+}1,b)$ and the indicator of y modulo $\mathfrak{m}_D(\vartheta)$.

LEAN Data.pointDescent · Data.iotaPlus · Data.descentMove · Data.liftMove

Lemma 9.6. *In Setting 2.1, let D be admissible data, $z \in \{0,1\}$ and i, j natural numbers with $i \le m$ and $j \le m$. Then $\ker^{z}_{i,j}(D)$ is a conjugate kernel pair.*

Proof. The index set has at most $2\,n_m(D)$ elements (this count is in unit 147), and

$$n_m(D) = k(D) + m\,(5r+1) \le r + 12\sqrt{x}\,r \le 2r^2$$

by (D2). By (I14)(iv) the entries of the parameter at each τ are distinct, of the right parity, and differ by at least $2\,h(D) = 4r^8 \ge 1000\,(4r^2)^3$ at indices of different signs; so (I16) applies. □

LEAN Data.isConjKernelPair_gridKernel

Lemma 9.7. *In Setting 2.1, let D be admissible data, ϑ an m-fold twist of D, $c \in \{0,1\}$, l a natural number and n a finite index set.*

(i) *$\mu^{\mathrm{gr}}_{D,l}(\vartheta; c, n)$ has weight $\mathrm{gw}_D(c,l,n)$ and tame part $\psi^{\mathrm{gr}}_{D,l}(\vartheta; c)$.*

(ii) *Let n' be a finite index set, $\mathbf{s}$ signs on n' and k an element of the stabiliser $\mathcal{K}_0$ of the standard lattice in $\mathrm{U}_{n'}(\mathbb{A}_f)$. Then the value of $\mu^{\mathrm{gr}}_{D,l}(\vartheta; c, n)$ at the determinant of the adelic point $(1,k)$ of the unitary group of the signs $\mathbf{s}$ is*

$$\prod_{w \mid \mathfrak{m}_D(\vartheta)} \psi^{\mathrm{gr}}_{D,l}(\vartheta; c)_w(\det(k \bmod w)),$$

the value at $\det(k \bmod \mathfrak{m}_D(\vartheta))$ of the character of $(\mathcal{O}_{E(D)}/\mathfrak{m}_D(\vartheta))^{\times}$ with these components. In particular it does not depend on n.

Proof. (i) By Theorem B(iii) the first factor has weight $-w_{D,l+1}(\tau)$ and the stated tame part; by (I8) and (I7), multiplying by v^y adds y to the weight. (ii) By Lemma 3.5(ii) and Definition 6.1, the tame part is trivial outside the chosen places and the places of $Q(\vartheta)$, which by (I15) are the prime divisors of $\mathfrak{m}_D(\vartheta)$; apply (I17) with (i). □

LEAN `Data.gridChar_hasWeight` · `Data.gridChar_det`

Lemma 9.8 (steps of the grids are edges)**.** *In Setting 2.1, let D be admissible data, $z \in \{0,1\}$, i,j natural numbers, I a set, $\vartheta = (\vartheta_y)_{y\in I}$ a family of m-fold twists of D and $d \in \{0,1\}$. Let $c \in \{0,1\}$ and natural numbers l, i', j' be given by $(c,l,i',j') = (z,i,i+1,j)$ if $d = 1$ and $(c,l,i',j') = (1-z,j,i,j+1)$ if $d = 0$, and suppose $i' \le m$ and $j' \le m$. Then the characters $n \mapsto \mu^{\mathrm{gr}}_{D,l}(\vartheta_y; c, n)$, $y \in I$, the kernel pairs $\ker^z_{i,j}(D)$ and $\ker^z_{i',j'}(D)$, the direction d and the polynomial $\mathrm{har}_D(0,d,c,l;z;i,j;i',j')$ form an edge family.*

Proof. By Lemma 9.7(i) the characters have the weights $\mathrm{gw}_D(c,l,\cdot)$, which do not depend on y. By (I14)(v) weights, parameters and signs at the two nodes correspond, and (I16) gives the edge family. □

LEAN `Data.isEdgeFamily_grid`

Lemma 9.9 (the two grids meet)**.** *In Setting 2.1, let D be admissible data and j a natural number.*

(i) If $j \le m$, then $\mathcal{V}^1_{j,j}[0](D)$ is the orthogonal sum of $\mathcal{V}^0_{j,j}[0](D)$ and the standard line of sign $(-1)^j$, relabelled along the bijection Δ_j of (I14)(iii).

(ii) There is a bijection from $\underline{\mathcal{V}}^0_{j+1,j}(D)$ to $\underline{\mathcal{V}}^1_{j,j+1}(D)$ that carries the signs $\mathrm{sgn}^{0,0}_{j+1,j}(D)$ to $\mathrm{sgn}^{1,0}_{j,j+1}(D)$ and along which $\mathcal{V}^1_{j,j+1}[0](D)$ is the relabelling of $\mathcal{V}^0_{j+1,j}[0](D)$.

Proof. (i) For $j = 0$ both sides are $Y_0(D) \oplus I(+1)$ by Definition 9.1, and Δ_0 is the identity. For $j \ge 1$ both $\mathcal{V}^1_{j,j}[0](D)$ and $\mathcal{V}^0_{j,j}[0](D)$ are standard signed spaces. A sum of standard signed spaces is the standard signed space of the two families of signs, and its relabelling is the standard signed space of the transported signs, which are $\mathrm{sgn}^{1,0}_{j,j}(D)$ by (I14)(iii).

(ii) Both index sets have $r + (2j+1)\,t(D)$ elements by (I14), since $t(D) \ge 1$. By (I14)(ii) the numbers of signs -1 are $\lfloor(\max(m-j-1,0)+1)/2\rfloor$ and $\lfloor\max(m-j,0)/2\rfloor$, which agree. So there is a bijection carrying one family of signs to the other. Both spaces are standard signed spaces by Definition 9.1, since $j+1 \ne 0$; relabelling one gives the other. □

LEAN `Data.gridSpace_diag` · `Data.gridSpace_subdiag`

Lemma 9.10. *In Setting 2.1, let D be admissible data, ϑ an m-fold twist of D, $z \in \{0,1\}$ and a,b natural numbers, and suppose that $z = 1$ or $a \ne 0$. Then*

$$\mathrm{ix}_D(\vartheta; z, a, b) = \left|\mathrm{GL}_{\underline{\mathcal{V}}^z_{a,b}(D)}(\mathcal{O}_{E(D)}/\mathfrak{m}_D(1_D))\right|.$$

In particular it does not depend on ϑ.

Proof. Under the hypothesis, $\mathcal{K}_D(\vartheta;(z,a,b))$ is the kernel of the reduction

$$\mathrm{GL}(\mathcal{O}_{E(D)}/\mathfrak{m}_D(\vartheta)) \longrightarrow \mathrm{GL}(\mathcal{O}_{E(D)}/\mathfrak{m}^{\triangle}_D(1,\vartheta)),$$

and $\mathfrak{m}_D^{\triangle}(1,\vartheta) = \mathfrak{m}_D(1_D)$ by (I15). The index of a kernel is the order of the image, and the reduction is surjective: by (I15) reduction from $\mathcal{K}_0$ is surjective and factors through it. □

LEAN `Data.levelIndex_eq_untwisted`

10 Where the results are used

The objects of Sections 3 to 7 are used in every later chapter. The level $N(D)$ and the element $\pi_N(D)$ define the level of the columns of Chapter V (unit 145) and the split places where the Gauss-sum operator of the note *Chains of definite theta lifts and the Gauss-sum operator* acts; the lower bound $\log N(D) \geq \mathrm{tar}(D)$ of Theorem A(ii) is what lets a power of $N(D)$ pay for the excess of size over divisibility in the last step of the theorem on short forms (unit 151), and the form of $\mathrm{tar}(D)$ enters the admissibility of the filling data (unit 148). The characters $\mu_{D,j}(\vartheta)$ are those of the j-th theta lift in the seesaw identity and in Chapter VII; the index sets $\underline{X}_j(D)$ and $\underline{Y}_j(D)$ carry the definite and the indefinite chain. The group $\mathsf{G}(D)$ and the idempotent $e_0(D)$ define the rows (unit 140). Pairs are the arguments of the ratios of L-values of Chapters VII and VIII. Theorem C and everything of Section 9 are used only in the folder of the exchange identity (unit 147); so are entry signs and Lemma 7.7.

11 Notes on the formal text

Arguments that the census lists and Lean does not take. The lists of arguments used by the build of this note are read from the text of the source, not printed by Lean. In the file of index types a line of the form *variable* declares a finite place w and natural numbers a, n, j for the whole file, and the reading attributes such a variable to a declaration whenever its name occurs in it, also as the name of a field or of a bound variable. So it lists w among the arguments of the definitions of $\mathrm{Ch}_i(D)$, $\mathrm{Pair}(D)$, the row parameter, $\mathrm{Tame}(D)$, $\mathrm{n}(\vartheta)$, $\mathrm{Tw}(D)$, $\mathrm{Good}(D)$ and of statements of Theorem B and of Lemmas 3.2(v) and 4.2; a type T in Lemma 3.3 (it is the character there); a number a in Lemma 5.1(i); a number n in the definition of $\underline{X}_j^{\circ}(D)$ (the name occurs as the name of the function $n_j(D)$); two numbers a, j in the definition of entry signs (they are names of pattern variables); an index set n in the definition of $\mathcal{K}_D(\vartheta;p)$ (it names an argument of another function); and the field with its structures and a finiteness in Lemma 9.7(ii). Lean takes none of these. For the last three definitions this note therefore writes the notation with Lean's arguments (D and j; o, j, a; ϑ and p) and not with the census's. In the other direction, the reading takes the source of each of the four linear maps of Definition 9.5 for an argument; the notation shows the form to which the map is applied in that place. The arguments of $\mathrm{Bl}_j(S,T)$ are, in Lean's order, S, T and the number j.

Implicit data in Section 9. In the file of the grid spaces the data D are an implicit argument of every definition, so the notations of that section show D as a fixed letter and not in a slot of their own; they are to be read with the D of Setting 2.1.

Where the formal statements differ from the ones above. Theorem A(iii): the formal proof takes the square root of -1 from a lemma of the background library on fields containing a root of unity of order 5040; the proof above takes it from the root of unity of $E(D)$. Lemma 3.2(iii) repeats "w is chosen" on its right-hand side, as the formal statement does; its content is that a chosen place lies above g_0 or g_1. Lemma 7.4: the formal lemma is the count $|\underline{R}(D)| = r$; the other two statements are added here. Definition 7.5(b): the formal text divides $k(D)$ by 2 as an integer, which is exact; the index $i+2-k(D)$ is a truncated difference of natural numbers, used only for $i+1 \geq k(D)$. Definition 4.3: the formal structure names its components *character*, c, ψ, z; the bound $4b$ is a real number. Definition 6.1(a): the coprimality is stated for the natural numbers $g(D) \cdot N(D)$ and $\prod_{w \in Q} \mathrm{N}w$. Theorem C: the hypotheses on the signs force all three families to be 1, so the theorem concerns definite groups only; the letter for the sign on the point is an argument of the formal statement although it is determined. In (a1) the formal statement quantifies over all rings S with an involution and all fields R of characteristic 0, as above; the expression $\langle v', Bv \rangle$ is bilinear there, in (a3) and in the mean of (b). In (b) the constant C depends on g only: it is chosen after g and before the space, the forms, u and the level; the statement does not say that $C \neq 0$. Input (I11) is the case $q = 0$ of a formal statement with one more parameter. Lemma 9.8: the two bounds $i' \leq m$, $j' \leq m$ are arguments with a default proof by arithmetic. Lemma 9.9(i): the hypothesis $j \leq m$ enters only through the signs of (I14)(iii).

Members that nothing refers to by name. The reader's dossier lists a few members of the unit to which no other declaration refers by name. Those of this note are: the statement $\pi_g \neq 0$ of Lemma 3.2(i), which Lean's simplifier uses, and the bound for the root discriminant (Lemma 5.1(ii)) and the finiteness of $\mathrm{Bl}_j(S, T)$ (Lemma 7.2), which are instances found by Lean's search. The instances of the file of index types that have no name have no line in the concordance; they are mentioned in Lemmas 5.1(iii) and 3.2(v), after Lemma 7.4, in Remark 5.5 and after Definition 6.1. Whether a hypothesis of a formal statement is unused was not determined: no Lean was run.

How this note was written. From the dossier of the unit: the texts of its members and the structured proofs of the declarations treated here. I read the two Lean files of this note completely, the proof of Theorem C line by line, and compared every statement of this note with the Lean statement, argument by argument, with the lists of arguments of the census and of the dossier. For the Inputs I read the Lean statements of (I6), (I9) to (I12) and the definitions behind (I13) to (I17) in the files of Chapters III and VII and of the background library; I opened none of their proofs. The proofs of Lemma 5.1, of Theorem A(i) and of Lemma 9.6 replace Lean's automatic comparisons of sizes by explicit inequalities from (D1) to (D3), and are mine; so are the proof of Theorem A(iii) and the wording of the interlacing in the proof of Theorem C, which the formal text does by a case analysis left to automation. Two step claims of the dossier were corrected against the Lean text: in Theorem B(i) the residue characters are trivial at the root of unity (the dossier says that their order divides $M_\omega(P, \mu)$), and in Theorem C(a3) the vector of equal norm is attached to $\mathrm{br}\, v$, not to v'. The program check of the unit's dossier covered 503 leaf steps of 83 proofs.

Revision. After an independent referee's report and the second reading of the catalogue, Inputs (I6) and (I16) state the status of the cited literature as the catalogue records it (in both cases the relation is unresolved), and the index of the middle vector of the shape is written $\diamond$, apart from the point $*$.

Appendix A. Concordance with the Lean artifact

The formal names of the objects: `P.N₀`, `P.d` are N_0, d; the fields `D.logX`, `D.logB`, `D.s`, `D.m`, `D.r`, `D.g`, `D.piG` are $\log x$, $\log b$, μ, m, r, (g_0, g_1), π_g; `D.Φ` is $\mathrm{Pl}(D)$, `D.w j τ` is $w_{D,j}(\tau)$, `D.nominalWeight` the nominal weight, `D.gProd` is $g(D)$, `P.Mω D.s` is $M_\omega(P, \mu)$; `star` is complex conjugation; `w.q` is $\mathrm{N}w$; `AutChar` is the group of characters of $\mathrm{U}(1)$ and `HasWeight` the relation "has weight and tame part"; `WeilData.upsilonU1` is υ; truth values are written 1 and 0. Three statements as they stand in the artifact:

```
structure TameChar where
  toAutChar : AutChar D.E
  Q : Finset _
  (ψ) hasWeight : toAutChar.HasWeight 0 ψ
  ψ_eq_one : ∀ w ∉ Q, ψ w = 1
  star_notMem : ∀ w ∈ Q, star w ∉ Q
  coprime : (D.gProd * D.N).Coprime (∏ w ∈ Q, w.q)

def μ₀ := D.muFlat * (WeilData.upsilonU1 ^ (-D.h : ℤ) * D.x) ^ j

def gridSpace : ∀ o z i j, Space D.E _ (D.gridSigns z o i j)
  | 0, true, 0, 0 => ((D.spaceY 0).sum (signedSpace ..)).reindex (.refl _) D.gridSigns_zero.symm
  | 0, false, 0, j => D.spaceY j | _ + 1, _, 0, 0 => (gridSpace ..).neg | _, _, _, _ =>
    signedSpace ..
```

Notation

$P = (N_0, d)$, $K(P)$ parameters; the field $\mathbb{Q}(\sqrt{-d})$

D admissible data for P (Setting 2.1)

x, x_1, b the three scales of D

μ, m, r the exponent, the number of lifts and the rank of D

g_0, g_1, $g(D)$, π_g the two primes of D, their product, an integer of $K(P)$ of norm $g_0 g_1$

$C(P)$ the constant of P of Chapter III

$E(D)$, $N_1(D)$, ς_D the CM field of D; the order of its root of unity; that root

$\mathrm{Pl}(D)$, τ, $f(D)$ the infinite places of $E(D)$; one of them; their number

$\mathrm{thick}(D)$ the thick places

w, $\overline{w}$, $\mathbb{F}_w$, $\mathrm{N}w$ a finite place of $E(D)$; its conjugate; residue field; absolute norm

$\mathcal{O}$, $\mathbb{A}_f$ rings of integers; the finite adeles of the field in question

$\mathrm{rd}_{E(D)}$, $\varpi(P,\mu)$, $\Omega(P,\mu)$, $\mathrm{cs}(d)$ root discriminant; generator of the different; the period; a constant of d

$M_\omega(P,\mu)$ the number $(N_0 d)^{\mu+6}$

$k(D)$, $t(D)$, $h_2(D)$, $h(D)$, $n_j(D)$ the numbers $r+1-m$, $5r$, r^8, $2r^8$, $k(D)+j(t(D)+1)$

$a(D)$, $b_1(D)$, $b_2(D)$ least multiples of $N_1(D)$ above xb, $a(D)/x$, $a(D)/x_1$

$w_{D,j}(\tau)$, $w_D(\tau)$ the weights; the nominal weight

$\bar{\pi}_g(D)$ the conjugate of π_g in $\mathcal{O}_{E(D)}$

$w \in \mathrm{Ch}(D)$, $w \notin \mathrm{Ch}(D)$ w is, is not, a chosen place of D

$\mathrm{Ch}_i(D)$, $\mathrm{pl}_D(x)$ chosen places above g_i; the place of a pair $x = (i, w)$

$\omega_{D,w}$, $\omega_{D,\bullet}$, T, T_w residue character at w; the family; characters of order $M_\omega(P,\mu)^2$

$\mathrm{U}(1)$, U_n the norm-one group; the unitary group of the identity matrix

ν, $\mathbf{e}$, ψ a character of U(1) (in Definition 7.1, a bijection); a weight; a tame part

υ the splitting character on U(1)

$\mu^\flat_D$, χ°_D, $\mu^0_{D,j}$ the three characters of Definition 4.1

$\mathrm{Pair}(D)$, $(\nu, \mathbf{c}, \psi, z)$ the pairs of D; a pair

$\mathrm{tar}(D)$, $N(D)$, $\pi_N(D)$ the target; the level; an integer of norm $N(D)$

U, p, M_0, Ψ, Ψ_0, ς_0 in Section 5: a real number, a prime, $N_1(D)/N_0$, cyclotomic polynomials of orders $N_1(D)$ and N_0, a root of unity of order N_0

u, q, y, y' an element or adele of norm one; natural numbers and integers bound in a statement

$\mathrm{Tame}(D)$, $\mathrm{Tw}(D)$, 1_D tame characters and twists of D; the trivial one

ϑ, $Q(\vartheta)$, ψ_ϑ, $\mathrm{n}(\vartheta)$ a tame character; its set of places; its tame part; the product of the norms of the places of $Q(\vartheta)$

$\mu_{D,j}(\vartheta)$, $\psi_{D,j}(\vartheta)$, $\mathrm{Lf}(D)$ character and tame part of the j-th lift; the set $\{1, \dots, m\}$

$[q]$, $\{*\}$ the set $\{0, \dots, q-1\}$; a set with one element

S, T, α, $\mathrm{Bl}_j(S,T)$ sets; S and j copies of T

in_j, $\mathrm{eq}_j(\nu)$ inclusion of the first block; a bijection

$\varrho(D)$ the number $m/2-1$

$\underline{X}^\circ_j(D)$, $\underline{X}_j(D)$, $\underline{R}(D)$, $\underline{Y}_j(D)$ index sets: of $X_j(D)$ without its last vector, of $X_j(D)$, of $Y_0(D)$, of $Y_j(D)$

$\mathfrak{s}(D)$ the shape of $Y_0(D)$

num_D a numbering of $\underline{R}(D)$

$\mathrm{par}_{D,\tau}(i)$, $\mathrm{par}^W_{D,\tau}(i)$ the row parameter; its double on $\underline{R}(D)$

$\mathrm{sg}^W_{D,j}(i)$, $\mathrm{sg}(o,j,a)$ signs of the spaces W_j; entry signs

$\mathsf{G}(D)$, $\mathrm{Good}(D)$, $e_0(D)$, c_x, e_{c_x} the finite group; good families; the idempotent; a polynomial and its idempotent

E, n, n', N in Section 8: a CM field, index sets, the number $|n|$

(κ, e), (κ', e'), $(\kappa^\natural, e^\natural)$ weights

$\kappa^\uparrow$, $\kappa^\downarrow$ the two parts of κ in (I11)

l, l', $\mathrm{hc}^N_{\kappa,e}(\tau,p)$ families of parameters; the doubled Harish-Chandra parameter

$\lambda_\tau(p)$, $\lambda^\natural_\tau(q)$, $\delta_\tau(q)$ highest weights; their difference

$\mathbf{s}$, $\mathbf{r}$, $\mathbf{t}$, σ signs; a bijection $n \sqcup \{*\} \to n'$

$\rho_{\kappa,e}$, $\overline{\rho_{\kappa,e}}$ the representation of weight (κ, e); at conjugate matrices

$\langle v', v\rangle$, (v', v), $\|v\|$ dot product; Gram form; Weyl norm

$\mathrm{boxes}(\kappa, N)$ the number of boxes of κ in rank N

S, R, f_τ, g, h rings; ring homomorphisms; group elements

B, A, br, N_τ, M, C integer matrices; exponents; a natural number; a constant

V, η, ϕ, Φ, F a standard space; algebraic forms; an automorphic function; a form

$F_\eta^{l,\mathrm{s}}$, v_l^+, $v^\natural$, v° the function of a form; highest vector; vectors

$\mathcal{K}$, $\mathcal{K}_0$, $\mathrm{mean}_{\mathcal{K}}(F)$ a level; the maximal one; the mean at level $\mathcal{K}$

$\mathrm{diag}_\sigma(g, u)$ block diagonal matrix along σ

L', L_h linear functionals

z, c, d elements of $\{0, 1\}$: a grid, twisted or not, a direction; z is a natural number in a pair, c a natural number in Theorem B and Lemma 3.2

o, i, j, a, b, l, i', j' natural numbers: an offset and positions on the grids (b also the third scale, l also a parameter)

$I(\mathbf{s})$, $Y_j(D)$ standard signed space; the hermitian space $Y_j(D)$

$\underline{\mathcal{V}}^z_{i,j}(D)$, $\mathrm{sgn}^{z;o}_{i,j}(D)$, $\mathrm{gpar}^{z;o}_{i,j}(D, \tau)$ index set, signs and doubled parameter of a node

$\mathrm{gw}_D(c, l, n)$, $\mathrm{har}_D(o, d, c, l; z; a, b; i, j)$ grid weight; joint harmonic

$\mathfrak{m}_D(\vartheta; q)$, $\mathfrak{m}_D(\vartheta)$, $\mathfrak{m}^{\triangle}_D(z, \vartheta)$, $\mathfrak{a}$ moduli; an ideal

$p = (z, a, b)$, $\underline{\mathcal{V}}_D(p)$ a node; its index set

$\mathcal{V}^z_{i,j}[o](D)$ the space at a node

$\ker^z_{i,j}(D)$, $\mathcal{F}^z_{a,b}(D)$, $\mathcal{F}^{\mathrm{lev}}_i(D)$ kernel pair; forms at a node; forms of level

$\mu^{\mathrm{gr}}_{D,l}(\vartheta; c, n)$, $\psi^{\mathrm{gr}}_{D,l}(\vartheta; c)$ character and tame part on the grids

$\mathrm{to}_D(z, \vartheta, b)$, $\mathcal{K}_D(\vartheta; p)$, $\mathrm{ix}_D(\vartheta; z, a, b)$ an order; the level at a node; its index

$\mathrm{desc}^z_{D,b}(\vartheta)(F)$, $\iota^{+,z}_{D,b}(\vartheta)(F)$ descent by one step; iterated descent

$\mathrm{desc}_D[y](F)$, $\mathrm{lift}_D[y](F)$ descent and lift with the indicator of y

Σ a finite set of finite places

V, Z the two grids ($z = 0$, $z = 1$); V is also a standard space

Δ_j, k, I, $\mathcal{S}$, $\mathcal{T}$ a bijection; an element of $\mathcal{K}_0$; an index set of a family; spaces

i, π, e a square root of -1; an integer of norm $N(D)$ (also the number π); Euler's number

(Cited by the catalogue for the edge statement behind Input (I16); its second reading finds that the formal two-sided statement goes beyond the published joint-type criterion, so the relation is unresolved.)

For Inputs (I11) and (I12) the catalogue has no confirmed reference for the statements used here: reference to be confirmed.

Theta functions of a CM elliptic curve: periods, tight frames, conjugates and divisibility of jets

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. On the definite unitary groups of Theorem A of the write-up, a theta lift is a finite sum of Taylor coefficients at the origin (*jets*) of theta functions. This unit shows that these theta functions are products of translates of one function, the theta function θ_C of an elliptic curve with complex multiplication by $K = \mathbb{Q}(\sqrt{-d})$, composed with linear forms given by a *tight frame* in the CM field E (Theorem A, Proposition 5.2). Everything else is then read off the curve: the conjugates of the jets under $\mathrm{Aut}(\mathbb{C}/K)$ are jets again, of bounded size (Theorem B); suitably scaled jets are integral at every prime (Theorem C); at a prime p that is inert or ramified in K a product of theta series is, after a change of scale, an integral series times one exponential (Theorem D), which makes jets along products of minors divisible by an explicit power of p (Theorem E), and this power cannot be improved by much (Theorem F). The unit also defines the numbers that the next unit uses to state the divisibility of the whole chain of lifts: the ask, the gain, the loss and the column counts.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, attributed to L. Alpöge with the AI system Claude, whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. That headline is a *claim*: the authors report that every file compiles and that Lean's kernel accepted the proofs; the record of checks of the handout says who replayed what; nothing was compiled for this note; no mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note treats one unit, the folder on the CM curve: all 89 of its 89 declarations. Every statement below was compared with its Lean text, argument by argument. Proofs are given in full for what the unit itself proves; results of other units are stated as *Inputs* with the unit that owns them, and results of the background library of the artifact (complex multiplication, the Chowla–Selberg formula, the formal group of the curve, the Weil representation) are *quoted*, with a reference where the catalogue of the handout has one. Where a formal step is closed by automation that I could not follow without running Lean, §12 says so. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 89 declarations.

1 The statements

The notation is that of §2. $P = (N_0, d)$ are parameters and μ is a natural number; $E(P,\mu)$ is the CM field obtained from $K(P) = \mathbb{Q}(\sqrt{-d})$ by adjoining a root of unity of order $N_1(P,\mu)$, $\mathrm{Pl}(P,\mu)$ is the group of its infinite places, and $\iota_\tau \colon E(P,\mu) \to \mathbb{C}$ is the chosen embedding at the place τ. A *p-adic place* is a prime number p with a ring homomorphism $j \colon \mathbb{C} \to \mathbb{C}_p$; $|\cdot|_p$ is the absolute value of $\mathbb{C}_p$ and $\mathfrak{o}_p$ its ring of integers. The numbers $s_1(P,\mu)$ and $\mathrm{per}(P,\mu)$ are the period factor and the scale of the jets (Definition 2.1), $T^V_a f$ is the series of jets of a vector f of the Weil representation of a hermitian space V at the scale a (Background 4), and $\mathrm{Std}_\delta(V)$ is the module of standard data (Definition 2.2).

Theorem A (tight frames with a unit vector). Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number and $j \colon \mathbb{C} \to \mathbb{C}_p$ a ring homomorphism. Let M and c_* be natural numbers with $(d \cdot N_1(P,\mu))^6\,(c_* + 1) \le M$. Then there are a finite set I, elements $v_i \in E(P,\mu)$ and natural numbers c_i, for $i \in I$, such that the family $(v_i)_{i\in I}$ with the multiplicities $(c_i)_{i\in I}$ is a tight frame of length M (Background 1), $c_* \le c_i$ for every $i \in I$, and for some $i \in I$

$$|j(s_1(P,\mu)\cdot\overline{\iota_\tau(v_i)})|_p = 1 \qquad \text{for every } \tau \in \mathrm{Pl}(P,\mu)$$

(for $c_* \ge 1$ this vector occurs in the frame with positive multiplicity; for $c_* = 0$ its multiplicity may be 0).

LEAN `Parameters.exists_isTightFrame`

Theorem B (conjugates of jets). Let $P = (N_0, d)$ be parameters, μ a natural number, n a finite set and V a standard hermitian space over $E(P,\mu)$ with index set n. Let R be a set of finite places of $E(P,\mu)$ that contains the complex conjugate of none of its members, and let $\sigma \in \mathrm{Aut}(\mathbb{C}/K(P))$. Then there are $t \in \mathbb{C}$, $c \in \mathbb{C}$, a finite adele z of $E(P,\mu)$ with $z\bar{z} = 1$ and a σ-semilinear map $L \colon \mathcal{S}(V) \to \mathcal{S}(V)$ with values in $\mathcal{W}_{\mathrm{f}}(V)$ such that:

(i) $|t|^2 = \Omega(P,\mu)^{-1}$, and $c \neq 0$;

(ii) for every $f \in \mathcal{W}_{\mathrm{f}}(V)$, applying σ to the coefficients of $T^V_{\mathrm{per}(P,\mu)} f$ gives the series $T^V_t(Lf)$ with every variable $z_{(\tau,i)}$ replaced by $z_{(\mathrm{perm}_\mu(\sigma)^{-1}\tau,\,i)}$, where $\mathrm{perm}_\mu(\sigma)$ is the permutation of $\mathrm{Pl}(P,\mu)$ with $\sigma \circ \iota_\tau = \iota_{\mathrm{perm}_\mu(\sigma)(\tau)}$ for every τ;

(iii) for every $f \in \mathcal{W}_{\mathrm{f}}(V)$ and every $g \in \mathrm{U}_n(\mathbb{A}_{\mathrm{f}})$: $L(\omega_V(1,g)f) = \dfrac{\sigma(\Delta_{\mathrm{f}}(g))}{\Delta_{\mathrm{f}}(g)} \cdot \omega_V(1,g)(Lf)$;

(iv) for every $x \in \mathbb{A}_{\mathrm{f}}^n$, every $g \in \mathrm{U}_n(\mathbb{A}_{\mathrm{f}})$ and every adelic vector $y \in \mathbb{A}^n$:

$$\left|L(\mathfrak{h}_V(x^\flat)\,\omega_V(1,g)\,\theta^\circ_V)(y)\right| \;\le\; \exp(C(P)\cdot(N_1(P,\mu)\,|n|+1)^2),$$

where $C(P)$ is the constant of the parameters of the note on the CM field (unit 152); it is $C_{\mathrm{gen}}(P) + 2d + 6$ plus non-negative terms, $C_{\mathrm{gen}}(P)$ being the constant of Proposition 6.1;

(v) for every Schwartz–Bruhat function Ψ above R: $L(\mathrm{name}_{V,R}(\Psi)\mathrm{vac}_V) = c \cdot \omega_V(1, z\cdot 1_n)(\mathrm{name}_{V,R}(\sigma\circ\Psi)\mathrm{vac}_V)$.

LEAN `Parameters.exists_semilinear_isJetConjugate`

Theorem C (integrality of jets). Let $P = (N_0, d)$ be parameters, μ a natural number, n a finite set, V a standard hermitian space over $E(P,\mu)$ with index set n, p a prime number and $j\colon \mathbb{C} \to \mathbb{C}_p$ a ring homomorphism. Let δ be a nonzero integer of $K(P)$ and $f \in \mathrm{Std}_\delta(V)$. Let Q be a polynomial in the variables $z_{(\tau,i)}$, $(\tau,i) \in \mathrm{Pl}(P,\mu) \times n$, with coefficients in O_j, and Q' the same polynomial with its coefficients read in $\mathbb{C}$. Then

$$|j\Big(\mathrm{jet}_{Q'}(T^V_{\overline{\delta}\cdot d\cdot \mathrm{per}(P,\mu)} f)\Big)|_p \;\le\; 1,$$

where $\mathrm{jet}_{Q'}(F) = (Q'(\partial)F)(0)$ is the jet of a power series F along Q'.

LEAN `Parameters.norm_jet_jetSeries_le_one`

Theorem D (normal form of theta products at a non-split prime). Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number with $\chi_{K(P)}(p) \neq 1$ and $j\colon \mathbb{C} \to \mathbb{C}_p$ a ring homomorphism. Then there are $\varpi \in \mathbb{C}_p$ and $\varpi_0 \in \mathfrak{o}_p$ with

$$|\varpi|_p = p^{-\varrho_d(p)}, \qquad |\varpi_0|_p = p^{(\chi_{K(P)}(p)-1)/2},$$

such that for every finite set I, every real number $r \le 1$ and every $\Theta \in \mathrm{ThProd}_{P,\mu}(1, r; I)$:

(a) for every natural number B,

$$\Theta \text{ is integral on the null cone of } (\mathrm{pr}, S_B; \varpi, \varpi_0) \text{ up to degree } B,$$

where $\mathrm{pr}_e(v) = [-p^e]_{P,\mu} \cdot v$ and S_B is the set of the natural numbers $e \le \lfloor \log_p B \rfloor$ such that e is odd or $p = d$;

(b) if $\chi_{K(P)}(p) = -1$ and $r = 1$, there are $\kappa \in \mathbb{C}_p$ and power series Ψ, V with coefficients in $\mathfrak{o}_p$, in the variables z_x, $x \in \mathrm{Pl}(P,\mu) \times I$, such that $|\kappa|_p = p^{1-1/(p-1)}$, $\Psi(0) = 0$,

$$\Theta(\varpi z) = \exp(\kappa\Psi) \cdot V,$$

and for every variable x and every exponent β: the coefficient at z^β of the reduction of $\partial\Psi/\partial z_x$ modulo $\mathfrak{m}_p$ is nonzero if and only if $\beta = p^e \cdot 1_y$ for an odd e and a variable $y = (v,i)$ with $([-p^e]_{P,\mu} \cdot v,\, i) = x$; here 1_y is the exponent of z_y.

LEAN `Parameters.thetaProducts_normal_form`

Theorem E (divisibility of Schur jets). Let p be a prime number, Φ, n, n' finite sets, and $\varkappa\colon \Phi \times \mathbb{N} \to \mathbb{N}$ a family of column counts that fits the ranks $|n|$, $|n'|$ (Background 5). Let $\mathrm{pr}\colon \mathbb{N} \times \Phi \to \Phi$ be a map, $S \subset \mathbb{N}$ and $\Xi \subset \Phi$ finite sets, ρ, ω real numbers, $\varpi \in \mathbb{C}_p$ with $|\varpi|_p = p^{-\rho}$, $\varpi_0 \in \mathfrak{o}_p$ with $|\varpi_0|_p = p^{\omega}$, and Θ a power series over $\mathbb{C}_p$ in the variables $z_{(\tau,b,c)}$, $(\tau,b,c) \in \Phi \times n' \times n$. Let $g\colon \Phi \times \mathbb{N} \times n' \to \mathbb{N}$ be a function (the *charges*) such that for all $e \in S$, $\tau \in \Phi$, $h \in \mathbb{N}$ and $b \in n'$:

$$\tau \in \Xi \ \text{ or } \ (h = 1 \text{ and } \mathrm{pr}_e(\tau) \in \Xi) \quad \Longrightarrow \quad g(\tau,1,b) \neq 0 \ \text{ or } \ g(\mathrm{pr}_e(\tau),h,b) \neq 0.$$

Let i' and i be Weyl indices for $\varkappa$ of ranks $|n'|$ and $|n|$, and put $N = |n'|$, $B = \mathrm{box}(\varkappa, N)$ and $m = \sum_{\tau\in\Phi}\sum_{h<N}\sum_{l<\varkappa(\tau,h)}\sum_{b<h} g(\tau,h,i'_\tau(h,l,b))$, the total charge of the boxes of i'. Suppose that

$$\Theta \text{ is integral on the null cone of } (\mathrm{pr}, S; \varpi, \varpi_0) \text{ up to degree } B.$$

Then

$$|\,\mathrm{SJ}_\varkappa(\Theta)_{i',i}|_p \ \le \ p^{\,m-\left((\frac{1}{p-1}-\rho)B+\omega\sum_{e\in S}\sum_{\tau\in\Phi}\mathrm{cc}_p(\varkappa,N;\Xi;\tau,\mathrm{pr}_e(\tau);e)-|\Phi|\,N^3(\lfloor\log_p B\rfloor+1)\right)}.$$

LEAN `norm_schurJet_le`

Theorem F (a jet that is not more divisible). Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number with $\chi_{K(P)}(p) \neq 1$ and $j\colon \mathbb{C} \to \mathbb{C}_p$ a ring homomorphism. Let N be a function from the exponents in the variables z_τ, $\tau \in \mathrm{Pl}(P,\mu)$, to the non-negative real numbers, Θ a power series over $\mathbb{C}_p$ in these variables, n an exponent, and i, y functions from $\mathrm{Pl}(P,\mu)$ to $\mathbb{N}$. Suppose that (i,y) is a Frobenius packing of n at p; that $\Theta(0) = 1$; that Θ is carried by one copy and Θ^{-1} by five copies of N (Background 6); and that $\Theta \in \mathrm{ThProd}_{P,\mu}(1,1;\{*\})$. Then there are exponents $\beta \le n$ and $\gamma \le n$ with $|\beta| = \sum_\tau y_\tau(p^{i_\tau}+1)$ and $|\gamma| = \sum_\tau y_\tau$ such that β is a sum of six exponents $\alpha_1, \dots, \alpha_6$ with

$$\prod_{k=1}^{6} \mathsf{N}(\alpha_k) \ \ge \ p^{\,(1-\frac{1}{p-1})|\gamma|+\varrho_d(p)\,|\beta|+\sum_\tau v_p(\gamma_\tau!)}.$$

LEAN `exists_hasLargeSplit_of_pairs`

How the pieces fit (motivation, read from the comments of the formal text and from the places where later units use the results; not statements of this unit). A column on the definite group is lifted by integrating it against a theta kernel, and on a definite group this integral is a finite sum of matrices of jets $\mathrm{SJ}_\varkappa(T_c^V f)$ of data f (Background 5). Theorem A and Proposition 5.2 turn the series $T_c^V f$ into products of Taylor series of translates of θ_C; the scale $\mathrm{per}(P,\mu)$ is chosen so that these products have p-adic absolute values governed by the period factor $s_1(P,\mu)$ and archimedean conjugates governed by $\Omega(P,\mu)$. Theorem C says that one lift cannot lower p-adic valuations by more than a power of $\overline{\delta}d$ (Proposition 7.4), which is all one needs at the primes that split in K. At the other primes the formal group of the curve has

height two. There the logarithm of θ_C keeps a denominator only in the degrees $p+1$ and $p+q$ of a good parameter (Proposition 8.4); a derivative of order a gains about $a/(p-1)$ powers of p, and the exponential $\exp(\kappa\Psi)$ takes back what the couplings of a variable at τ with the variables at the partner places $[-p^e]_{P,\mu}\cdot\tau$ allow. The balance is the number $\mathrm{ask}_{D,p}(y,\tau)$ of Definition 2.6, summed in the gain $\mathrm{gain}(D,p)$; it is the local form, at p, of the weight $\lambda_{d,1}$ of the prime sum of the main inequality. Theorem F shows that the count is sharp, which the unit on the rows needs for a lower bound.

2 The setting

Conventions. $\mathbb{N}=\{0,1,2,\dots\}$; subtraction of natural numbers is truncated at 0 and division of natural numbers is the floor, as in the formal text. *Parameters* are a pair $P=(N_0,d)$: a positive multiple N_0 of 18480 and a prime number $d\equiv N_0/2-1 \bmod N_0$; the *exponent* is a natural number μ. A statement about *data* concerns admissible data D for parameters P, with components x, x_1, b (the three scales), m, r and the exponent $\mu(D)$. Index sets such as n, n', I, J, Φ are finite sets; a hermitian space V has an index set n and signs $\varepsilon\colon n\to\{1,-1\}$. In a statement about a prime number p and a ring homomorphism $j\colon\mathbb{C}\to\mathbb{C}_p$, the absolute value $|\cdot|_p$ of $\mathbb{C}_p$ is normalised by $|p|_p=p^{-1}$, $\mathfrak{o}_p=\{x\in\mathbb{C}_p : |x|_p\le 1\}$, $\mathfrak{m}_p$ is its maximal ideal, and $O_j=\{z\in\mathbb{C} : |j(z)|_p\le 1\}$; such a pair (p,j) is called a p-adic place. In a statement about a field E with a CM type and Weil data, about a commutative ring of characteristic p, about a normed field, or about an integral domain of characteristic 0, these structures are part of the statement. v_p is the p-adic valuation of a natural number, and for a natural number B, $\lfloor\log_p B\rfloor$ is the largest $e\in\mathbb{N}$ with $p^e\le B$, and 0 if $B=0$ (as in the formal text). For a multi-index (an *exponent*) β, $|\beta|$ is its degree, $\beta!$ the product of the factorials of its entries, and $\beta\le\beta'$ is meant entry by entry.

The unit rests on four bodies of earlier material. They are recalled in six numbered paragraphs, after the definitions and the comments of the formal text; the notes of the units that own them give the details.

Background 1: the field, its lattice, tight frames (unit 152, the note on the CM field; the definition of a frame is in the background library). For parameters $P=(N_0,d)$ and $\mu\in\mathbb{N}$: $K(P)=\mathbb{Q}(\sqrt{-d})\subset\mathbb{C}$ with ring of integers $\mathcal{O}_{K(P)}$; $\chi_{K(P)}$ is its quadratic character, on integers the Legendre symbol χ_d modulo d; $N_1(P,\mu)$ is N_0 times a power of 3 and a power of 2 fixed by μ; $E(P,\mu)=K(P)(\varsigma(P,\mu))$ with $\varsigma(P,\mu)$ a primitive root of unity of order $N_1(P,\mu)$. The set $\mathrm{Pl}(P,\mu)$ of infinite places of $E(P,\mu)$ is a group, identified with $\mathrm{Gal}(E(P,\mu)/K(P))$ and with $(\mathbb{Z}/N_1(P,\mu))^\times$; $\iota_\tau\colon E(P,\mu)\to\mathbb{C}$ is the embedding at τ that is the identity on $K(P)$, and $\iota_\tau=\iota_1\circ\mathrm{gal}(\tau)$ for the automorphism of τ. For an integer ν, $[\nu]_{P,\mu}$ is the place of the class of ν if ν is prime to $N_1(P,\mu)$, and the unit place otherwise. Every prime dividing $N_1(P,\mu)$ divides $(d+1)/4$ and splits in $K(P)$. Further: $c_0(P,\mu)=(1+\sqrt{-d})/2$ as an integer of $E(P,\mu)$; $\partial(P,\mu)$, the value at $\varsigma(P,\mu)$ of the derivative of the cyclotomic polynomial of order $N_1(P,\mu)$, which generates the different of $E(P,\mu)$ over $K(P)$ and divides $N_1(P,\mu)$; the finite idele $\alpha(P,\mu)$ of $E(P,\mu)$ with component $\partial(P,\mu)^{-1}$ at the primes that contain $c_0(P,\mu)$ and 1 elsewhere; the root discriminant $\mathrm{rd}_{E(P,\mu)}$; and $\Omega(P,\mu)=\exp(\mathrm{cs}(d))\cdot 2\pi/\mathrm{rd}_{E(P,\mu)}$, where $\mathrm{cs}(d)$ is Euler's constant

minus $\mathrm{Re}(L'/L)(1,\chi_d)$. We write $\mathbb{A}$, $\mathbb{A}_{\mathrm{f}}$, $\widehat{\mathcal{O}}$ for the adeles, the finite adeles and the integral finite adeles of the field in question, and

$$\mathfrak{a}(P,\mu) = \{x \in E(P,\mu) : \ \alpha(P,\mu)^{-1}x \in \widehat{\mathcal{O}}\},$$

a fractional ideal that contains the integers of $E(P,\mu)$. Let I be a finite set, $w_i \in E(P,\mu)$ and $m_i \in \mathbb{N}$ for $i \in I$, and $M \in \mathbb{N}$. The family (w_i) with multiplicities (m_i) is a *tight frame of length* M if every w_i lies in $\mathfrak{a}(P,\mu)$ and

$$\sum_{i\in I} m_i\, \iota_\tau(w_i)\,\overline{\iota_{\tau'}(w_i)} = \begin{cases} M & \tau = \tau', \\ 0 & \tau \neq \tau' \end{cases} \qquad \text{for all } \tau,\tau' \in \mathrm{Pl}(P,\mu).$$

So the vectors $(\iota_\tau(w_i))_\tau$ of $\mathbb{C}^{\mathrm{Pl}(P,\mu)}$, repeated m_i times, resolve M times the identity: they replace an orthonormal basis, which the lattice need not have.

LEAN in the background library: `IsTightFrame`, `finiteImage` · the objects of the field are in the concordance of the note on the CM field

Background 2: embeddings into $\mathbb{C}_p$. Let (p,j) be a p-adic place and $\psi\colon E(P,\mu) \to \mathbb{C}_p$ a ring homomorphism. It induces a prime $\mathfrak{p}_\psi$ of $E(P,\mu)$, the set of integers x with $|\psi(x)|_p < 1$, and extends continuously to the completion at $\mathfrak{p}_\psi$; composed with the projection of $\mathbb{A}_{\mathrm{f}}$ to that completion this is a ring homomorphism $\hat{\psi}\colon \mathbb{A}_{\mathrm{f}} \to \mathbb{C}_p$. For $\tau \in \mathrm{Pl}(P,\mu)$ put $j_\tau(x) = j(\iota_\tau(\overline{x}))$, so that $j(\overline{\iota_\tau(x)}) = j_\tau(x)$. Two facts are quoted: $|\psi(x)|_p \le 1$ for integers x, and $|\hat{\psi}(a)|_p \le 1$ for $a \in \widehat{\mathcal{O}}$.

LEAN in the background library: `PadicPlace`, `placeOfEmb`, `adeleExtension`, `weightEmbedding`, `norm_ringOfIntegers_le`, `norm_adeleExtension_le_one`

Background 3: a CM datum and its theta function. Let d be a prime $\equiv 7 \bmod 8$ and $\mathcal{O}_d$ the ring of integers of $\mathbb{Q}(\sqrt{-d})$, embedded in $\mathbb{C}$. A *CM datum for* d is a triple C of a lattice $\Lambda_C \subset \mathbb{C}$ with $\mathcal{O}_d\Lambda_C \subset \Lambda_C$, a point t with $2t \in \Lambda_C$, $t \notin \Lambda_C$, and a number a_1, normalised by $\wp''(t) = 2$ (written $g_2 = 12\wp(t)^2 - 4$) and $a_1^2 = 12\wp(t)$, with $\frac{1+\sqrt{-d}}{2}t \notin \Lambda_C$ and $\frac{1-\sqrt{-d}}{2}t \notin \Lambda_C$; $\wp$ and σ_C are the Weierstrass functions of Λ_C and $\mathrm{area}(C)$ is the area of a fundamental parallelogram. For $m \in \mathbb{N}$ and $y \in \mathbb{C}$ the *twisted translation* of a function F on $\mathbb{C}$ is

$$(U_y^{C,m}F)(z) = \exp(-m\pi(z\overline{y} + |y|^2/2)/\,\mathrm{area}(C))\,F(z+y),$$

and the *theta function* of C is $\theta_C(z) = (U_t^{C,1}\sigma_C)(z)/(U_t^{C,1}\sigma_C)(0)$: an entire function with $\theta_C(0) = 1$, a section of degree one for the Riemann form of Λ_C. Further $\xi_C(z) = \wp(z+t) - \wp(t)$ and $\varphi_C(z) = \frac{1}{2}(\wp'(z+t) - a_1\xi_C(z))$, which vanishes at 0 with derivative 1; for a triple $x = (x_1,x_2,x_3)$ of natural numbers, $\mathrm{mon}_C(x) = \theta_C^{x_1}\sigma_C^{2x_2}(\varphi_C\theta_C^3)^{x_3}$ is the *monomial section* of degree $x_1 + 2x_2 + 3x_3$. *Conjugate data.* For every complex number α that is the number a_1 of some CM datum for d we fix one such datum C_α (a choice). For $\sigma \in \mathrm{Aut}(\mathbb{C}/\mathbb{Q}(\sqrt{-d}))$ the number $\sigma(a_1)$ is again the invariant of a CM datum for d (quoted), and the *conjugate datum* is $\sigma C = C_{\sigma(a_1)}$: the chosen datum with invariant $\sigma(a_1)$. It is defined for the automorphisms that fix $\mathbb{Q}(\sqrt{-d})$ only. (The choice matters little: by the normalisation, $g_2 = 12\wp(t)^2 - 4$ and $g_3 = 4\wp(t)^3 - g_2\wp(t)$ with $\wp(t) = a_1^2/12$, so a_1 determines the lattice Λ_C and the class of t modulo it.) $\mathrm{Tay}(F)$ is the Taylor series at 0 of an entire function F, and for a p-adic place (p,j), $\mathrm{Tay}_j(F) \in \mathbb{C}_p[[X]]$ is $\mathrm{Tay}(F)$ with j applied to its coefficients. The ring

$$\mathfrak{o}_p[[\varphi_C]] = \{G(\mathrm{Tay}_j(\varphi_C)) : \ G \in \mathfrak{o}_p[[X]]\} \subset \mathbb{C}_p[[X]]$$

depends on j. For a natural number $M \geq 1$ and $r \in \mathbb{N}$, $[F]_{r \bmod M}$ is the part of a series $F \in \mathbb{C}_p[[X]]$ in the degrees $\equiv r \bmod M$. The following are quoted.

(Q1) *Normalisation.* For every nonzero fractional ideal $\mathfrak{c}$ of $\mathbb{Q}(\sqrt{-d})$ there are a CM datum C for d and $u \in \mathbb{C}^\times$ with $\Lambda_C = u\,\mathfrak{c}$; then $\operatorname{area}(C) = |u|^2\,\mathrm{N}(\mathfrak{c})\sqrt{d}/2$. (Elementary.)

(Q2) *Main theorem of complex multiplication, soft form.* Let C be a CM datum for d with $\Lambda_C = \Omega_* \mathcal{O}_d$ and $\sigma \in \operatorname{Aut}(\mathbb{C}/\mathbb{Q}(\sqrt{-d}))$. There are $\Omega \in \mathbb{C}^\times$ with $\operatorname{area}(\sigma C) = |\Omega|^2\sqrt{d}/2$, an integer $e \geq 1$ with $e\Omega \in \Lambda_{\sigma C}$, a finite adele β of $\mathbb{Q}(\sqrt{-d})$ and elements $a_S \in \mathbb{Q}(\sqrt{-d})$, one for each finite set $S \subset \mathbb{Q}(\sqrt{-d})$, with β a cluster point of the a_S (embedded diagonally in the finite adeles) as S grows, such that for every finite S and every $x \in S$

$$\sigma(\operatorname{Tay}(U^{C,1}_{x\Omega_*}\theta_C)) = \operatorname{Tay}(U^{\sigma C,1}_{x\Omega a_S}\theta_{\sigma C}).$$

Reference: G. Shimura, *Introduction to the Arithmetic Theory of Automorphic Functions* (1971), Thm. 5.4; J. Milne, *Complex Multiplication* (2020), 9.17. Relation: a *weaker form* (the catalogue calls it the soft form: the adele is not identified with the Artin map, and nothing is said about its invertibility; places confirmed at second hand).

(Q3) *Chowla–Selberg formula, logarithmic form.* For a CM datum C for d there is $u \in \mathbb{C}$ with $|j(u)|_p = 1$ at every p-adic place (p, j) and $\operatorname{area}(\sigma C) \cdot |\sigma(u)|^2 = \pi \exp(\operatorname{cs}(d)) \cdot 2\pi/\sqrt{d}$ for every $\sigma \in \operatorname{Aut}(\mathbb{C}/\mathbb{Q}(\sqrt{-d}))$. The artifact cites Selberg and Chowla, *On Epstein's zeta-function*; the catalogue has no entry for this declaration: *reference to be confirmed.*

(Q4) *Integrality of a_1.* $|j(a_1)|_p \leq 1$ at every p-adic place. Catalogue: a *weaker form* of the good reduction everywhere of the normalised CM curve (Milne, *loc. cit.*; place not confirmed). Also quoted: a complex number x with $|\iota(x)|_2 \leq c$, for one real number c and every field isomorphism ι from $\mathbb{C}$ onto an algebraic closure of $\mathbb{Q}_2$ (whose absolute value is $|\cdot|_2$), is algebraic over $\mathbb{Q}$.

(Q5) *The parameter φ_C.* $\operatorname{Tay}_j(\varphi_C)$ has constant term 0 and linear coefficient 1; the ring $\mathfrak{o}_p[[\varphi_C]]$ is stable under d/dX and contains $\operatorname{Tay}_j(\xi_C)$. If $T \in \mathfrak{o}_p[[\varphi_C]]$ has $T(0) = 0$, $T'(0) = 1$, then $\mathfrak{o}_p[[\varphi_C]] = \{G(T)\}$, and the inverse series Z of T satisfies: $F \in \mathfrak{o}_p[[\varphi_C]]$ if and only if $F(Z)$ has coefficients in $\mathfrak{o}_p$. For every k the largest absolute value of the k-th coefficient of an element of $\mathfrak{o}_p[[\varphi_C]]$ is attained at a power of $\operatorname{Tay}_j(\varphi_C)$; the same holds in two variables for the ring of integral series in $\operatorname{Tay}_j(\varphi_C)(X)$, $\operatorname{Tay}_j(\varphi_C)(Y)$, and this ring contains $\operatorname{Tay}_j(\varphi_C)(X+Y)$ (the addition law). (The catalogue has no entry for these declarations: *reference to be confirmed.*)

(Q6) *Logarithm of theta.* There are $L \in \mathbb{C}_p[[X]]$ and $L_2 \in \mathbb{C}_p$ with $\operatorname{Tay}_j(\theta_C) = \exp(-L)$, $L(0) = L'(0) = 0$, $L'' = L_2 + \operatorname{Tay}_j(\xi_C)$, $|j(\sqrt{-d})\,L_2|_p \leq 1$, and for every pair (a, N) in the closure $\mathcal{N}_d \subset \mathbb{C}_p^2$ of the pairs $(j(\delta), j(\delta\overline{\delta}))$, $\delta \in \mathcal{O}_d$: the series $\operatorname{Tay}_j(\varphi_C)(aX)$, $\exp(NL - L(aX))$ and $(NL - L(aX))'$ lie in $\mathfrak{o}_p[[\varphi_C]]$. Moreover, with q the norm of a prime of $\mathbb{Q}(\sqrt{-d})$ above p: $(\zeta, \zeta^{p+1}) \in \mathcal{N}_d$ for every $\zeta \in \mathbb{C}_p$ with $\zeta^q = \zeta$, $|\zeta|_p = 1$. (Substantial; the artifact points to Bannai–Kobayashi and to Mazur–Tate for comparable statements; reference to be confirmed.)

(Q7) *Torsion translates.* Let $\delta \in \mathcal{O}_d$, $\delta \neq 0$, and $y \in \mathbb{C}$ with $\delta y \in \Lambda_C$. Then $\mathrm{Tay}_j(U_y^{C,1}\theta_C)(j(\bar{\delta})X) = \mathrm{Tay}_j(\theta_C)^{\delta\bar{\delta}} \cdot u$ for some $u \in \mathfrak{o}_p[[\varphi_C]]$. Also: if x is a triple of degree m and $My \in \Lambda_C$ for a natural number $M \neq 0$, then $|j((U_y^{C,m}\,\mathrm{mon}_C(x))(0))|_p \leq 1$. (Substantial; the artifact points to Bannai–Kobayashi, Duke Math. J. 153 (2010), 2.14–2.16, and to Tate's telescoping for local heights; not compared: *reference to be confirmed.*)

(Q8) *Height of the formal group.* (i) If $|(F')_{p-1}|_p < 1$ for every $F \in \mathfrak{o}_p[[\varphi_C]]$, then $|(\mathrm{Tay}_j(\xi_C))_{p-1}|_p \geq 1$ and $\chi_d(p) \neq 1$. (ii) Let Z be as in (Q5), $a \in \mathcal{O}_d$ with $a\bar{a} = q$ odd, and $g \in \mathfrak{o}_p[[X]]$ with $g(0) = 0$ and $Z(g) = j(a)Z$; then $|g_k|_p = 1$ for some $k \leq q$. References: Deuring's criterion; J. Silverman, *The Arithmetic of Elliptic Curves*, IV.7 (place confirmed for (ii)); relation: *weaker forms* (one direction of the criterion; an upper bound for the height).

Background 4: the Weil representation and jets (background library). Let E be a CM field with a CM type, whose embeddings ι_τ are indexed by the infinite places, and with Weil data (a splitting character and a finite idele α; for $E(P,\mu)$ these are fixed in unit 152, with $\alpha = \alpha(P,\mu)$). A *hermitian space* V over E with index set n and signs ε is a hermitian matrix over E with an adelic point that brings it to the diagonal form ε at the infinite places and to the unit form at the finite ones; it is *standard* if all signs are 1 and the point is 1. I_n is the standard space with index set n, and $\mathrm{Hom}(I_n, I_{n'})$, with index set $n' \times n$, is standard too. The space $\mathcal{S}(V)$ is the Banach space of the Weil representation: integrable functions on $\mathbb{A}^n$ with a reproducing identity. It carries the Heisenberg operators $\mathfrak{h}_V(y)$, $y \in \mathbb{A}^n$; the vacuum vector vac_V; the theta functional $\mathrm{Th}_V\colon \mathcal{S}(V) \to \mathbb{C}$, invariant under the rational vectors; the Weil representation ω_V of the adelic unitary group, whose elements we write (g_∞, g) with $g \in \mathrm{U}_n(\mathbb{A}_\mathrm{f})$; and the pairing $\langle f, f'\rangle_V = \int \bar{f} f'$. A vector $f \in \mathcal{S}(V)$ is a function on $\mathbb{A}^n$ through $f(y) = \mathrm{Th}_V(\mathfrak{h}_V(y)f)$. For a finite adelic vector $x \in \mathbb{A}_\mathrm{f}^n$, $x^\flat \in \mathbb{A}^n$ is the vector with real part 0 and finite part αx. These operators compose by the rule

$$\mathfrak{h}_V(x^\flat)\,\mathfrak{h}_V(x'^\flat) = \psi_0\big(\tfrac{1}{2}\textstyle\sum_{i\in n} \overline{x'_i}\,x_i\big) \cdot \mathfrak{h}_V((x+x')^\flat) \qquad (x, x' \in \mathbb{A}_\mathrm{f}^n) \tag{1}$$

(quoted), where ψ_0 is the standard additive character of $\mathbb{A}_\mathrm{f}$, whose values are roots of unity; $\mathfrak{h}_V^\mathrm{f}(x)$ is $\mathfrak{h}_V(x^\flat)$ times a root of unity, so that $\mathfrak{h}_V^\mathrm{f}(x)\mathfrak{h}_V^\mathrm{f}(x') = \psi_0(\cdot)\mathfrak{h}_V^\mathrm{f}(x+x')$ with a value of ψ_0; and

$$\mathcal{W}_\mathrm{f}(V) = \text{the span over } \mathbb{C} \text{ of the vectors } \mathfrak{h}_V^\mathrm{f}(x)\mathrm{vac}_V,\ x \in \mathbb{A}_\mathrm{f}^n,$$

the *finite part.* $\Delta_\mathrm{f}(g)$ is the multiplier of $g \in \mathrm{U}_n(\mathbb{A}_\mathrm{f})$ in the Weil representation. For a set R of finite places and a function Ψ on $\mathbb{A}_\mathrm{f}^n$, $\mathrm{name}_{V,R}(\Psi)$ is the operator on $\mathcal{S}(V)$

named by Ψ (a combination of Heisenberg operators at the places of R and their conjugates); Ψ is *Schwartz–Bruhat above* R if it depends only on the components at the places of R, is locally constant, and the parts at R of its support lie in a compact set. For a modulus $\mathfrak{m}$ (a nonzero ideal divisible by no prime together with its conjugate) $P^{\mathfrak{m}}$ is the mean of the operators $\mathfrak{h}^{\mathrm{f}}_V(x)$ over the integral x supported at the primes dividing $\mathfrak{m}$ and their conjugates. For $a \in \mathbb{C}$ and $f \in \mathcal{S}(V)$ the *jet series* is the power series

$$T^V_a f = \sum_{\beta} \frac{a^{|\beta|}}{\beta!}\, \mathrm{Th}_V(v_\beta \otimes f)\, z^\beta \;\in\; \mathbb{C}[[z_{(\tau,i)} : \tau \text{ an infinite place},\ i \in n]],$$

where $v_\beta \otimes f$ is the integral of the Heisenberg translates of f against the Fock vector of the monomial z^β. For $f \in \mathcal{S}(V)$ and $y \in \mathbb{C}^{\mathrm{places}\times n}$, $\Theta_f(y)$ is the value of f at the real vector of y divided by the Gaussian; Lemma 5.1 says that $T^V_a f$ is the Taylor series of $z \mapsto \Theta_f(az)$ when the signs are 1 and $f \in \mathcal{W}_{\mathrm{f}}(V)$. Quoted facts are cited where they are used; the two that carry weight are:

(Q9) *Theta functions of a level are Weil translates.* Let V be standard over $E(P,\mu)$, δ an integer with $\delta\overline{\delta} = N \neq 0$, and S an entire function on $\mathbb{C}^{\mathrm{places}\times n}$ that has the transformation law of $\Theta_\cdot$ under translation by the real images of the vectors $\overline{\delta}\gamma$, $\gamma \in \mathfrak{a}(P,\mu)^n$. Then $S = \Theta_F$ for some $F \in \mathcal{W}_{\mathrm{f}}(V)$, and F has a *vacuum expansion for* (δ, N): a set A of $N^{2|\mathrm{places}||n|}$ indices, $x_a \in \mathbb{A}_{\mathrm{f}}^n$ with δx_a integral, and a natural number m_0 with $\sum_{a\in A} m_0\, \ell(\mathfrak{h}_V(x_a^\flat)\mathrm{vac}_V) \cdot \mathfrak{h}_V((-x_a)^\flat)F = |A|\, \ell(F) \cdot \mathrm{vac}_V$ for every linear form ℓ on $\mathcal{S}(V)$. (Substantial: Stone–von Neumann for a finite Heisenberg group; no source cited; reference to be confirmed.)

(Q10) *Galois action on the finite Weil representation.* Let σ be a ring endomorphism of $\mathbb{C}$, $L\colon \mathcal{S}(V) \to \mathcal{W}_{\mathrm{f}}(V)$ a σ-semilinear map, B a finite adele and R a set of finite places that contains the conjugate of none of its members. If $\sigma(\psi_0(z)) = \psi_0(B\overline{B}z)$ for all $z \in \mathbb{A}_{\mathrm{f}}$ and $L(\mathfrak{h}_V(x^\flat)f) = \mathfrak{h}_V((Bx)^\flat)(Lf)$ for all x and all $f \in \mathcal{W}_{\mathrm{f}}(V)$, then B is a unit and there are $c \in \mathbb{C}$ and $z \in \mathbb{A}_{\mathrm{f}}$, $z\overline{z} = 1$, with $L(\mathrm{vac}_V) = c\,\omega_V(1, z\cdot 1_n)\mathrm{vac}_V$ and with (iii) and (v) of Theorem B. Reference: G. Shimura, *Theta functions with complex multiplication*, Duke Math. J. 43 (1976), no place given; *reference to be confirmed.*

Background 5: column counts, Schur jets, gauges, kernels (background library). A family of *column counts* on a finite set Φ is a function $\varkappa\colon \Phi \times \mathbb{N} \to \mathbb{N}$; $\varkappa(\tau,h)$ is the number of columns of height h at τ of a family of Young diagrams, and $\mathrm{box}(\varkappa,N) = \sum_{\tau\in\Phi}\sum_{h<N} h\,\varkappa(\tau,h)$ counts the boxes in columns of height below N. It *fits the ranks* $|n| \le |n'|$ if $\varkappa(\tau,h) = 0$ for $|n| < h < |n'|$. A *Weyl index* of rank $|n|$ is a family $i = (i_\tau)_\tau$ of standard fillings: $i_\tau(h,l,b) \in n$ is the entry in the box $b < h$ of the l-th column of height $h < |n|$, $l < \varkappa(\tau,h)$; the Weyl indices index the coordinates of the representation of weight $(\varkappa, e)$ of $\prod_\tau \mathrm{GL}_n$, for $e\colon \Phi \to \mathbb{Z}$ the exponents of the determinants. The *Schur matrix* $S_\varkappa(z)$ of matrix variables $z_\tau = (z_{(\tau,b,c)})_{b\in n', c\in n}$ has polynomial entries indexed by a Weyl index i' of rank $|n'|$ and one i of rank $|n|$; its

row i' expresses the product of minors of $z_\tau y_\tau$ prescribed by i' in the products of minors of y_τ. For a power series F in the $z_{(\tau,b,c)}$, $\mathrm{SJ}_\varkappa(F)$ is the matrix of the jets of F along the entries of $S_\varkappa$. Over $E = E(P,\mu)$ with $\Phi = \mathrm{Pl}(P,\mu)$: an *algebraic form* of weight $(\varkappa, e)$ on I_n is a function on $\mathrm{U}_n(\mathbb{A}_\mathrm{f})$ with values in $\mathbb{C}^{\text{Weyl indices}}$, equivariant under the rational points; for a p-adic place (p,j), $g \in \mathrm{U}_n(\mathbb{A}_\mathrm{f})$ and a vector ξ, the *gauge* $\mathrm{gauge}_j^{\varkappa,e}(g;\xi)$ is the largest $|\cdot|_p$ of a coordinate of $g^{-1}\cdot j(\xi)$, where g^{-1} acts in weight $(\varkappa,e)$ through its images under the $\hat{\jmath}_\tau$; an element $g \in \mathrm{U}_n(\mathbb{A}_\mathrm{f})$ is *integral above* p if its components at the primes above p are integral with integral inverse. A *kernel* k from weight $(\varkappa,e)$ on I_n to weight $(\varkappa,e_a)$ on $I_{n'}$ with data in a complex vector space $\mathcal{D}$ consists of a representation ω_k of $\mathrm{U}_n(\mathbb{A}_\mathrm{f}) \times \mathrm{U}_{n'}(\mathbb{A}_\mathrm{f})$ on $\mathcal{D}$ and a linear map $\Phi \mapsto \mathrm{jm}_k(\Phi)$ from $\mathcal{D}$ to matrices (rows: Weyl indices of rank $|n'|$; columns: of rank $|n|$), equivariant under the rational points. Let a, b be characters of $\mathrm{U}(1)$ over E with weights e_a, e_b and tame parts ψ, ψ', let K be a level, and suppose that $\varkappa$ is a *lift weight*: it fits the ranks, $|n| < |n'|$, and $e_\tau = e_{b,\tau} + \varkappa(\tau,|n|)$. For $c \in \mathbb{C}$ the *theta kernel* $\mathrm{k}_\varkappa(c;a,b;K)$ has $\mathcal{D} = \mathcal{W}_\mathrm{f}(\mathrm{Hom}(I_n, I_{n'}))$, $\omega_k = \omega_{a,b}$ (the Weil representation of the pair, twisted by a and b) and $\mathrm{jm}_k(f) = \mathrm{SJ}_\varkappa(T_c^{\mathrm{Hom}(I_n,I_{n'})} f)$. Quoted: $\mathrm{SJ}_\varkappa(T_c^{\mathrm{Hom}(I_n,I_{n'})} f) = c^{\mathrm{box}(\varkappa,|n'|)}\,\mathrm{SJ}_\varkappa(T_1^{\mathrm{Hom}(I_n,I_{n'})} f)$; the entries of $S_\varkappa$ have integral coefficients; every $g \in \mathrm{U}_n(\mathbb{A}_\mathrm{f})$ is a rational point times an element integral above p, and the gauge is unchanged by such elements on the right.

The definitions of the unit.

Definition 2.1 (the curve, its period, the scales)**.** Let $P = (N_0, d)$ be parameters and μ a natural number.

(a) $s_0(P,\mu) = \left(\chi_\mathrm{fin}(\alpha(P,\mu))^{-1}\right)^{1/f}$, the principal value of the root, where $f = |\mathrm{Pl}(P,\mu)|$ and $\chi_\mathrm{fin}(a) = \upsilon(a)\,|a|^{-1/2}$ is the character of the finite ideles of $E(P,\mu)$ made from the splitting character υ of the Weil data and the idele norm.

(b) $\mathcal{E}(P)$ is a CM datum for d and $\Omega_0(P) \in \mathbb{C}^\times$ a number with $\Lambda_{\mathcal{E}(P)} = \Omega_0(P)\,\mathcal{O}_{K(P)}$, both chosen by (Q1) for the unit ideal.

(c) $\mathrm{asc}(P) = \sqrt{2\pi/\sqrt{d}}$, a positive real number.

(d) $s_1(P,\mu) = s_0(P,\mu)/u_P$, where u_P is the number chosen by (Q3) for the datum $\mathcal{E}(P)$.

(e) $\mathrm{per}(P,\mu) = s_1(P,\mu)\cdot \mathrm{asc}(P)/\Omega_0(P)$.

LEAN `Parameters.vacuumRoot` · `Parameters.cmCurve` · `Parameters.Ω₀` · `Parameters.areaScale` · `Parameters.periodFactor` · `Parameters.jetScale`

Definition 2.2 (the scaled vacuum and the standard data)**.** Let $P = (N_0, d)$ be parameters and μ a natural number.

(a) $\mathrm{vsc}(P,\mu)$ is the nonzero complex number c that Proposition 6.1(i) provides (by choice) for μ and the standard space of rank one.

(b) For a hermitian space V over $E(P,\mu)$ with index set n: $\theta^{\circ}_V = \mathrm{vsc}(P,\mu)^{|n|} \cdot \mathrm{vac}_V$, the *scaled vacuum*.

(c) For an integer δ of $K(P)$ and a set S of finite places of $E(P,\mu)$ (a predicate on them), $\mathrm{Lat}(\delta; S)$ is the group of the $x \in \mathbb{A}_{\mathrm{f}}^n$ such that δx_i is integral at every place of S, for all $i \in n$.

(d) For V as in (b), a p-adic place (p,j) and an integer δ of $K(P)$, $\mathrm{Std}_\delta(V)$ is the O_j-submodule of $\mathcal{S}(V)$ spanned by the vectors $\mathfrak{h}^{\mathrm{f}}_V(x)\theta^{\circ}_V$ with $x \in \mathrm{Lat}(\delta; \{w : w \mid p\})$. It depends on j, which is always the place of the statement.

LEAN `Parameters.vacuumScale` · `Parameters.intVacuum` · `Parameters.integralAfter` · `Parameters.standardData`

Definition 2.3 (data that raise gauges)**.** Let (p,j) be a p-adic place, k a kernel from weight $(\varkappa, e)$ on I_n to weight $(\varkappa, e_a)$ on $I_{n'}$ over $E(P,\mu)$ with data in $\mathcal{D}$, $d_1 \in \mathrm{U}_n(\mathbb{A}_{\mathrm{f}})$, $d_2 \in \mathrm{U}_{n'}(\mathbb{A}_{\mathrm{f}})$ and c a real number. Then $\mathrm{Raise}_k(d_1, d_2; c)$ is the set of the $\Phi \in \mathcal{D}$ such that

$$\mathrm{gauge}_j^{\varkappa, e_a}(h d_2; \mathrm{jm}_k(\omega_k(g,h)\Phi)\,\xi) \;\le\; \max(c,0) \cdot \mathrm{gauge}_j^{\varkappa, e}(g d_1; \xi)$$

for all $g \in \mathrm{U}_n(\mathbb{A}_{\mathrm{f}})$, $h \in \mathrm{U}_{n'}(\mathbb{A}_{\mathrm{f}})$ and all vectors ξ. It is closed under addition and contains 0.

LEAN `Kernel.raises`

Definition 2.4 (theta products)**.** Let $P = (N_0, d)$ be parameters, μ a natural number, (p,j) a p-adic place, δ an integer of $K(P)$, r a real number and c a finite set. Then $\mathrm{ThProd}_{P,\mu}(\delta, r; c)$ is the set of the power series Θ over $\mathbb{C}_p$ in the variables $z_{(\tau,k)}$, $(\tau,k) \in \mathrm{Pl}(P,\mu) \times c$, for which there are a finite set J, elements $w_i \in E(P,\mu)$ $(i \in J)$, natural numbers M and n, a number $b \in \mathbb{C}$ and numbers $y_{(i,k)} \in \mathbb{C}$ $((i,k) \in J \times c)$ such that $(w_i)_{i \in J}$ with multiplicities 1 is a tight frame of length M;

$$\Theta = \prod_{(i,k) \in J \times c} \mathrm{Tay}_j\big(U^{\mathcal{E}(P),1}_{y_{(i,k)}}\theta_{\mathcal{E}(P)}\big)\Big(\sum_\tau j\big(b\,\overline{\iota_\tau(w_i)}\big)\, z_{(\tau,k)}\Big);$$

$p \nmid M$ and $p \nmid n$; $|j(b)|_p = r$; and $n\,\delta\,y_{(i,k)} \in \Lambda_{\mathcal{E}(P)}$ for all (i,k).

LEAN `Parameters.thetaProducts`

Definition 2.5 (integrality on the null cone)**.** Let p be a prime number, Φ and c finite sets, $\mathrm{pr}\colon \mathbb{N} \times \Phi \to \Phi$ a map, $S \subset \mathbb{N}$ a finite set, $\varpi \in \mathbb{C}_p$, $\varpi_0 \in \mathfrak{o}_p$, $B \in \mathbb{N}$, and Θ a power series over $\mathbb{C}_p$ in the variables z_x, $x \in \Phi \times c$. We say that

$$\Theta \text{ is integral on the null cone of } (\mathrm{pr}, S; \varpi, \varpi_0) \text{ up to degree } B$$

if the following holds for every set T of variables and every family $(Z_x)_{x \in \Phi \times c}$ of power series $Z_x \in \mathfrak{o}_p[[T]]$ without constant term: if for every commutative ring Q of characteristic p, every ring homomorphism $\phi\colon \mathfrak{o}_p[[T]] \to Q$ with $\phi(\varpi_0) = 0$ and every $e \in S$

$$\phi\Big(\sum_{(\tau,k) \in \Phi \times c} Z_{(\tau,k)}^{p^e} \cdot Z_{(\mathrm{pr}_e(\tau),k)}\Big) = 0,$$

then every coefficient of degree at most B of the series $\Theta\big((\varpi Z_x)_x\big)$ has absolute value at most 1.

LEAN `IsIntegralOnNullCone`

The sum in the display is the *coupling* of exponent e of the family Z. The condition on it says that it lies in the ideal generated by p and ϖ_0 (take for Q the quotient by this ideal; if the ideal is the whole ring there is no such ϕ): the family is *null* modulo (p, ϖ_0) for the pairings of a variable, raised to the power p^e, with its partner at pr_e.

Definition 2.6 (ask, forced part, gain, loss)**.** Let D be admissible data for parameters $P = (N_0, d)$, with components x_1, b, m, and let p be a natural number. For a real number y and $\tau \in \mathrm{Pl}(D)$ put

$$\mathrm{ask}_{D,p}(y,\tau) = \frac{1-\chi_{K(P)}(p)}{2} \sum_{\substack{e\ge 1\\ e \text{ odd or } p=d}} \Big(\frac{y}{p^e} - w_D([-p^e]_D\cdot\tau)\Big)_+,$$

where $(\,\cdot\,)_+$ is the positive part, $w_D(\,\cdot\,)$ is the nominal weight of unit 152 ($a(D)/x$ at the thick places, $a(D)/x_1$ at the others) and the sum over $e \in \mathbb{N}$ is 0 if the family is not summable. Then

$$\mathrm{forced}(D,p) = \sum_{\tau\in\mathrm{Pl}(D)} \mathrm{ask}_{D,p}(w_D(\tau),\tau),$$

$$\mathrm{gain}(D,p) = m\Big(\sum_{\tau\in\mathrm{tops}(D)} \mathrm{ask}_{D,p}(a(D),\tau) + k(D)\,\mathrm{forced}(D,p)\Big),$$

$$\mathrm{loss}(D,p) = f(D)\,(\log b)^2\cdot\frac{a(D)}{p}\cdot m^*,$$

where $m^* = m$ if p is short for D and $m^* = 1$ otherwise. Here we say that

$$p \text{ is short for } D \quad \text{if } m \text{ divides } p-1 \text{ or } m \text{ divides } p+1,$$

and that p is small and not split for D if $p < x_1$ and $\chi_{K(P)}(p) \neq 1$. The sets $\mathrm{tops}(D)$ (the places of class 1 modulo N_0) and the numbers $a(D)$, $k(D)$, $f(D) = |\,\mathrm{Pl}(D)|$ are those of unit 152.

Lemma 3.1 (the period)**.** *Let $P = (N_0, d)$ be parameters and μ a natural number.*

(a) For every $\sigma \in \mathrm{Aut}(\mathbb{C}/K(P))$: $|\sigma(s_0(P,\mu))|^2 = \mathrm{rd}_{E(P,\mu)}/\sqrt{d}$.
(b) $\Omega(P,\mu) > 0$.
(c) $\mathrm{per}(P,\mu) \neq 0$.
(d) The lattice of $\mathcal{E}(P)$, as a module over $\mathcal{O}_{K(P)}$, is $\Omega_0(P)\cdot\mathcal{O}_{K(P)}$.
(e) $\Omega_0(P) \in \Lambda_{\mathcal{E}(P)}$.

Proof. (a) Write $\alpha = \alpha(P,\mu)$, $\partial = \partial(P,\mu)$, $f = |\mathrm{Pl}(P,\mu)|$. Quoted from the background library: there are $k \geq 1$ and $y \in E(P,\mu)^\times$ with $\chi_{\mathrm{fin}}(\alpha)^k = \prod_\tau \iota_\tau(\overline{y})$. By (I2) this number is a norm, so it lies in $K(P)$ and σ fixes it; hence $|\sigma(\chi_{\mathrm{fin}}(\alpha))| = |\chi_{\mathrm{fin}}(\alpha)|$. Since $s_0(P,\mu)^f = \chi_{\mathrm{fin}}(\alpha)^{-1}$ and $|v| = 1$,

$$|\sigma(s_0(P,\mu))|^{2f} = |\chi_{\mathrm{fin}}(\alpha)|^{-2} = |\alpha|,$$

the idele norm of α (with components 1 at infinity). The idele $\alpha\overline{\alpha}\cdot\partial$, with ∂ embedded diagonally, is a unit at every finite place by (I1), so its idele norm is

$\prod_\tau |\iota_\tau(\partial)|^2$ (a quoted fact on ideles that are units at the finite places). By the product formula ∂ has idele norm 1, and $|\overline{\alpha}| = |\alpha|$; so $|\alpha|^2 = \prod_\tau |\iota_\tau(\partial)|^2$. By (I2), $\prod_\tau |\iota_\tau(\partial)| = \mathrm{rd}^f_{E(P,\mu)} / \sqrt{d}^f$. Taking f-th roots of non-negative numbers gives (a).

(b) All factors of $\Omega(P,\mu)$ are positive. (c) By (a) with $\sigma = 1$, $s_0(P,\mu) \neq 0$; by (Q3) with $\sigma = 1$, $u_P \neq 0$; $\mathrm{asc}(P) \neq 0$ and $\Omega_0(P) \neq 0$. (d) is the choice of $\mathcal{E}(P)$ and $\Omega_0(P)$, and (e) follows since $1 \in \mathcal{O}_{K(P)}$. □

Lemma 3.2 (the period factor at a p-adic place)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number and p a prime number.*

(a) For every ring homomorphism $\psi\colon E(P,\mu) \to \mathbb{C}_p$: $\hat{\psi}(\alpha(P,\mu)) = \psi(\partial(P,\mu))^{-1}$ if $c_0(P,\mu) \in \mathfrak{p}_\psi$, and $\hat{\psi}(\alpha(P,\mu)) = 1$ otherwise.

(b) For every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_p$ and every $\tau \in \mathrm{Pl}(P,\mu)$ we have $|j(s_1(P,\mu))|_p = |\hat{\jmath}_\tau(\alpha(P,\mu))|_p^{-1}$.

(c) For every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_p$, every $y \in \mathfrak{a}(P,\mu)$ and every $\tau \in \mathrm{Pl}(P,\mu)$: $|j(s_1(P,\mu) \cdot \overline{\iota_\tau(y)})|_p \leq 1$.

(d) For every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_p$: if $p \nmid N_1(P,\mu)$, then $|j(s_1(P,\mu))|_p = 1$.

Proof. (a) is the definition of $\alpha(P,\mu)$, read at the prime $\mathfrak{p}_\psi$. (b) Let $f = |\mathrm{Pl}(P,\mu)|$. By (Q3), $|j(u_P)|_p = 1$, so $|j(s_1(P,\mu))|_p^f = |j(s_0(P,\mu)^f|_p = |j(\chi_{\mathrm{fin}}(\alpha(P,\mu)))|_p^{-1}$. A quoted formula gives $|j(\chi_{\mathrm{fin}}(a))|_p = \prod_v |\hat{\jmath}_v(a)|_p$ for finite ideles a. By (a) the factor at v is $|j_v(\partial(P,\mu))|_p^{-1}$ or 1 according as $c_0(P,\mu) \in \mathfrak{p}_{j_v}$ or not. This factor does not depend on v: the condition reads $|j(\overline{c})|_p < 1$ for the complex number $c = (1+\sqrt{-d})/2$, because ι_v is the identity on $K(P)$ (I2); and $j_v(\partial(P,\mu)) = j_1(\mathrm{gal}(v)\partial(P,\mu))$ has the absolute value of $j_1(\partial(P,\mu))$ by (I3). So the product is the f-th power of the factor at τ.

(c) By (b), $|j(s_1(P,\mu)\overline{\iota_\tau(y)})|_p = |\hat{\jmath}_\tau(\alpha(P,\mu))|_p^{-1} |j_\tau(y)|_p = |\hat{\jmath}_\tau(\alpha(P,\mu)^{-1}y)|_p \leq 1$, since $\alpha(P,\mu)^{-1}y \in \widehat{\mathcal{O}}$ (Background 2). (d) Use (b) at $\tau = 1$. If $c_0(P,\mu) \notin \mathfrak{p}_{j_1}$ the factor is 1. Otherwise it is $|j_1(\partial(P,\mu))|_p^{-1}$; here $\partial(P,\mu)$ divides $N_1(P,\mu)$ (I3), which is a unit at $\mathfrak{p}_{j_1}$ because $p \nmid N_1(P,\mu)$, so $|j_1(\partial(P,\mu))|_p = 1$. □

Lemma 3.3 (the hermitian lattice)**.** *Let $P = (N_0, d)$ be parameters and μ a natural number.*

(a) For every $z \in E(P,\mu)$: $\mathrm{Tr}_{E(P,\mu)/K(P)}(z) = \sum_{\tau \in \mathrm{Pl}(P,\mu)} \iota_\tau(z)$ in $\mathbb{C}$.

(b) For all $x, y \in \mathfrak{a}(P,\mu)$: $\sum_{\tau \in \mathrm{Pl}(P,\mu)} \iota_\tau(x)\,\overline{\iota_\tau(y)} \in \mathcal{O}_{K(P)}$.

Proof. (a) The ι_τ are the composites of ι_1 with the elements of the Galois group, and ι_1 is the identity on $K(P)$. (b) The sum is $\mathrm{Tr}_{E(P,\mu)/K(P)}(x\overline{y})$ by (a). The finite adele of $x\overline{y}\,\partial(P,\mu)$ is the product of $\alpha(P,\mu)\overline{\alpha(P,\mu)}\partial(P,\mu)$, a unit everywhere by (I1), with the integral adeles $\alpha(P,\mu)^{-1}x$ and $\overline{\alpha(P,\mu)^{-1}y}$. So $x\overline{y}\,\partial(P,\mu)$ is an integer, $x\overline{y}$ lies in the inverse different of $E(P,\mu)$ over $K(P)$ by (I3), and its trace is integral. □

In other words, $\mathfrak{a}(P,\mu)$ with the form $\mathrm{Tr}(x\overline{y})$ is a unimodular hermitian lattice over $\mathcal{O}_{K(P)}$: $\mathfrak{a}(P,\mu)\cdot\overline{\mathfrak{a}(P,\mu)}$ is the inverse different.

4 Tight frames

Lemma 4.1 (the frame of the roots of unity)**.** *Let $P=(N_0,d)$ be parameters, μ a natural number and k a natural number. The family $(\varsigma(P,\mu)^i)_{0\le i<N_1(P,\mu)}$, each member with multiplicity k, is a tight frame of length $k\cdot N_1(P,\mu)$.*

Proof. $\varsigma(P,\mu)^i$ is an integer, and integers lie in $\mathfrak{a}(P,\mu)$ by (I1). For places τ,τ' put $q=\iota_\tau(\varsigma(P,\mu))\overline{\iota_{\tau'}(\varsigma(P,\mu))}$, a root of unity with $q^{N_1(P,\mu)}=1$. The sum of the frame identity is $k\sum_{i<N_1(P,\mu)}q^i$. If $\tau=\tau'$ then $q=1$. If $q=1$ then ι_τ and $\iota_{\tau'}$ agree on the generator $\varsigma(P,\mu)$ of $E(P,\mu)$ over $K(P)$, so $\tau=\tau'$. Hence the sum is $k\,N_1(P,\mu)$ for $\tau=\tau'$ and 0 otherwise. □

LEAN Parameters.isTightFrame_zeta_pow

Lemma 4.2 (a factor of the cyclotomic different)**.** *Let R be an integral domain of characteristic 0, N a natural number, $\zeta\in R$ a primitive root of unity of order N, and l a prime factor of N. Let Ψ_N be the cyclotomic polynomial of order N. Then there are natural numbers r and $M\le N$ with $N=l\,r$, such that a prime factor q of N divides M if and only if $q\neq l$, and an element $V\in R$ that divides M in R with*

$$\Psi_N'(\zeta)\,(\zeta^r-1)\,M=NV.$$

Proof. Write $N=l\,r$ and $r=l^aM$ with $l\nmid M$; then $M\le N$ and the prime factors of $N=l^{a+1}M$ other than l are those of M. Since $l\nmid M$, $\Psi_M(X^l)=\Psi_{Ml}(X)\Psi_M(X)$; replacing X by X^{l^a} and using $\Psi_{Ml}(X^{l^a})=\Psi_N(X)$ gives $\Psi_M(X^{l^{a+1}})=\Psi_N(X)\,\Psi_M(X^{l^a})$. Differentiate at ζ, a root of Ψ_N:

$$l^{a+1}\zeta^{l^{a+1}-1}\,\Psi_M'(\zeta^{l^{a+1}})=\Psi_N'(\zeta)\,\Psi_M(\zeta^{l^a}).$$

As $\Psi_M(Y)$ divides Y^M-1, the element $\Psi_M(\zeta^{l^a})$ divides ζ^r-1. So l^{a+1} divides $\Psi_N'(\zeta)(\zeta^r-1)$, and $N=l^{a+1}M$ divides $\Psi_N'(\zeta)(\zeta^r-1)M$; let V be the quotient. Next, r is a proper divisor of N, so $X^N-1=(X^r-1)\Psi_N(X)Q(X)$ for a polynomial Q over R; differentiating at ζ and multiplying by ζ gives $N=\Psi_N'(\zeta)(\zeta^r-1)\,Q(\zeta)\zeta$. Hence $NM=NV\cdot Q(\zeta)\zeta$, and $M=VQ(\zeta)\zeta$ because N is not a zero divisor: V divides M. □

LEAN Parameters.exists_cyclotomic_different_factor

Proof of Theorem A. Write $N=N_1(P,\mu)$, $\varsigma=\varsigma(P,\mu)$, $c_0=c_0(P,\mu)$, $\partial=\partial(P,\mu)=\Psi_N'(\varsigma)$ and $\nu=(d+1)/4$; so $c_0(1-c_0)=\nu$ and $\overline{c_0}=1-c_0$ (I4). The frame will be the union of the frame of Lemma 4.1 with a second family, built to contain a vector that is a unit against $s_1(P,\mu)$ at the primes above p.

Step 1: auxiliary numbers. For each prime factor l of N let r_l, M_l, V_l be as in Lemma 4.2 for $\zeta=\varsigma$ in the integers of $E(P,\mu)$, and put $a_l=\varsigma^{r_l}$, a primitive l-th root of unity. Every prime factor of N divides ν (I4), so N divides ν^N. The map $y\mapsto\nu y^2+y$ of $\mathbb{Z}/N$ is injective: if $\nu y^2+y=\nu y'^2+y'$ then $(y-y')(\nu(y+y')+1)=0$, and $\nu(y+y')+1$ is a unit because $\nu(y+y')$ is nilpotent. So the map is surjective, and

there are natural numbers $z < N$ and e with $\nu z^2 + z + 1 = Ne$. Put $t = 1 - c_0 + \nu z$. Then

$$t + \bar{t} = 1 + 2\nu z, \qquad t\,\bar{t} = \nu + \nu z + \nu^2 z^2 = \nu N e, \qquad (c_0 + \nu z)\,t = \nu N e. \tag{2}$$

Step 2: the second family. For a prime factor l of N and $0 \le h < r_l$, $0 \le k < l$, $0 \le i < l$ put

$$u_{l,h,k,i} = \varsigma^h\Big([k = 0]\,a_l^i + \lambda_l\,(a_l^i - a_l^k)\Big), \qquad \lambda_l = \frac{t\,M_l}{N}.$$

Claim: for all places τ, τ', $\sum_{h,k,i} \iota_\tau(u_{l,h,k,i})\overline{\iota_{\tau'}(u_{l,h,k,i})} = [\tau = \tau'] \cdot c_l$ with $c_l = N + M_l(1 + 2\nu(z + l\,M_l\,e))$. Let $A = \iota_\tau(a_l)$, $A' = \iota_{\tau'}(a_l)$ (primitive l-th roots of unity), $G = \sum_{i<l}(A\overline{A'})^i$, and let λ, λ' be the images of λ_l under ι_τ, $\iota_{\tau'}$. Using $\sum_{i<l} A^i = \sum_{i<l} \overline{A'}^{\,i} = 0$, the sum over k and i of the products of the two brackets is

$$G + \overline{\lambda'}G + \lambda G + 2l\,\lambda\overline{\lambda'}G = G\,(1 + \lambda + \overline{\lambda'} + 2l\lambda\overline{\lambda'})\,:$$

the four terms come from $k = 0$ with the two first summands, from $k = 0$ with one first and one second summand (twice), and from the two second summands. The sum over h contributes $\sum_{h<r_l}(\iota_\tau(\varsigma)\overline{\iota_{\tau'}(\varsigma)})^h$, and its product with G is $\sum_{h<N}(\iota_\tau(\varsigma)\overline{\iota_{\tau'}(\varsigma)})^h = N[\tau = \tau']$ by Lemma 4.1. For $\tau = \tau'$, (2) gives $\lambda + \overline{\lambda} = M_l(1 + 2\nu z)/N$ and $\lambda\overline{\lambda} = M_l^2 \nu e/N$, whence the claim. (The formal proof establishes this identity by a Gröbner basis computation.)

Step 3: lengths. Let $c = \sum_l c_l$. It is prime to N: modulo a prime factor q of N the summands with $l \ne q$ vanish, because q divides N and M_l, and $c_q \equiv M_q \not\equiv 0$, because q divides N and ν but not M_q. A crude bound, from $M_l, l, z \le N$, $e \le 2\nu N$ and at most N prime factors, is $c \le 8\nu^2 N^5$; with $9\nu^2 \le d^6$ and the hypothesis,

$$c_*(c + N) + (N - 1)(c - 1) \;\le\; (c_* + 1)\,9\nu^2 N^6 \;\le\; (dN)^6(c_* + 1) \;\le\; M.$$

Since c and N are coprime, every integer $\ge (N-1)(c-1)$ is a combination $Ac + BN$ with natural numbers A, B. Choose them with $Ac + BN = M - c_*(c + N)$. Take the vectors $u_{l,h,k,i}$ with multiplicity $A + c_*$ and the vectors ς^i, $i < N$, with multiplicity $B + c_*$. By the claim and Lemma 4.1 the frame identity holds with length $(A + c_*)c + (B + c_*)N = M$, and all multiplicities are at least c_*.

Step 4: the vectors lie in $\mathfrak{a}(P, \mu)$. For ς^i this is Lemma 4.1. For $u = u_{l,h,k,i}$ write $a_l^i - a_l^k = (a_l - 1)g$ with an integer g, and let w be a finite place. If $c_0 \in w$, the component of $\alpha(P, \mu)$ is ∂^{-1} and we need ∂u integral at w; indeed $\partial\lambda_l(a_l - 1) = tV_l$ by Lemma 4.2, so ∂u is an integer. If $c_0 \notin w$ the component is 1 and c_0 is a unit at w, so it suffices that $c_0^N\lambda_l$ is an integer, that is, that N divides $c_0^N t$. Now $c_0^N - (-\nu z)^N$ is divisible by $c_0 + \nu z$, and $(c_0 + \nu z)t = \nu N e$ by (2); so $c_0^N t \equiv (-z)^N \nu^N t \equiv 0$ modulo N, as N divides ν^N.

Step 5: the unit vector. If $|j(s_1(P, \mu))|_p = 1$, the vector $\varsigma^0 = 1$ will do. Otherwise p divides N by Lemma 3.2(d), and we take $u = u_{p,0,1,0} = \lambda_p(1 - a_p)$. Let τ be a place. By Lemma 3.2(b) and (a), $c_0 \in \mathfrak{p}_{j_\tau}$ (otherwise $|j(s_1(P, \mu))|_p = 1$), and

$$|j(s_1(P, \mu)\,\overline{\iota_\tau(u)})|_p = |j_\tau(\partial u)|_p = |j_\tau(tV_p)|_p,$$

since $\partial u = -tV_p$. This is at most 1. If it were smaller, tV_p would lie in $\mathfrak{p}_{j_\tau}$; but $t \equiv 1$ modulo $\mathfrak{p}_{j_\tau}$ (which contains c_0 and p, and p divides ν), so V_p and then M_p would lie in it, and p would divide M_p, against Lemma 4.2. □

5 Jets are Taylor coefficients of products of curve theta functions

Lemma 5.1 (jets and Taylor series)**.** *Let E be a field with a CM type and Weil data, n a finite set, V a hermitian space over E with index set n and all signs 1, and $f \in \mathcal{W}_{\mathrm{f}}(V)$. Write Φ for the set of infinite places of E.*

(a) For every $a \in \mathbb{C}$ and $v \in \mathbb{C}^{\Phi\times n}$: the Taylor series at 0 of the function $u \mapsto \Theta_f(u \cdot a \cdot v)$ of one complex variable is obtained from $T_a^V f$ by substituting $v_x\, u$ for the variable z_x, for all $x \in \Phi \times n$.

(b) If $a \in \mathbb{C}$, $a \neq 0$ and $T_a^V f = 0$, then $f = 0$.

(c) Let I be a finite set, G_i $(i \in I)$ entire functions on $\mathbb{C}$ and $\lambda_{c,i} \in \mathbb{C}^{\Phi\times n}$ for $c \in \mathbb{C}$, $i \in I$, such that $\Theta_f(c\,z) = \prod_{i\in I} G_i(\lambda_{c,i} \cdot z)$ for all $c \in \mathbb{C}$ and $z \in \mathbb{C}^{\Phi\times n}$, where $\lambda \cdot z = \sum_x \lambda_x z_x$. Then $\mathrm{Th}_V(f) = \prod_i G_i(0)$, and for every $c \in \mathbb{C}$

$$T_c^V f = \prod_{i\in I} \mathrm{Tay}(G_i)(\textstyle\sum_x \lambda_{c,i,x} z_x).$$

Proof. (a) Quoted from the background library: for $f \in \mathcal{W}_{\mathrm{f}}(V)$ the function Θ_f is an integral $\Theta_f(y) = \int f(w)\,\gamma(w)\exp(\langle w, y\rangle)\,dw$ over the real vectors w in Fock coordinates, with a Gaussian γ and a pairing that is linear in y; and the coefficient of z^β in $T_a^V f$ is the same integral with exp replaced by the monomial of β, times $a^{|\beta|}/\beta!$. Put $\ell(w) = a\langle w, v\rangle$. Then $\Theta_f(uav) = \int f\gamma\, e^{u\ell}$; expanding the exponential and exchanging sum and integral, which is allowed by dominated convergence because $|\ell(w)|$ is at most a constant times $|w|$ and $e^{c|w|}\gamma(w)|f(w)|$ is integrable, shows that the coefficient of u^k is $\int f\gamma\,\ell^k/k!$. This is the jet of $T_a^V f$ along $(\sum_x v_x z_x)^k/k!$, which is the coefficient of u^k after the substitution.

(b) By (a), for every y the entire function $u \mapsto \Theta_f(u\,a\,y)$ has Taylor series 0, so it vanishes; at $u = a^{-1}$ this gives $\Theta_f(y) = 0$. So f vanishes at all real vectors, and such a vector of $\mathcal{S}(V)$ is 0 (quoted).

(c) At $c = 0$, $z = 0$ the hypothesis reads $\mathrm{Th}_V(f) = \Theta_f(0) = \prod_i G_i(0)$. Fix c. Two power series in the z_x are equal if for every v they give the same series in u after the substitution $z_x \mapsto v_x u$ (compare the homogeneous parts as polynomial functions of v). After this substitution the left side is the Taylor series of $u \mapsto \Theta_f(u\,c\,v) = \prod_i G_i(u\,\lambda_{c,i} \cdot v)$ by (a), and the right side is the product of the Taylor series of the functions $u \mapsto G_i(u\,\lambda_{c,i} \cdot v)$; the Taylor series of a product of entire functions is the product of their Taylor series. □

LEAN `Space.taylor_line_eq_subst_jetSeries` · `Space.eq_zero_of_jetSeries_eq_zero` · `Space.jetSeries_eq_prod` · quoted: `entireTheta_eq_integral`, `Space.theta_integrated`, `jet_subst_linearSeries`, `Space.eq_zero_of_realVec`

Proposition 5.2 (a vector whose theta function is a product over a tight frame)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number, n a finite set and V a standard hermitian space over $E(P,\mu)$ with index set n. Let M and N be natural numbers with $N \neq 0$, I a finite set, $w_i \in E(P,\mu)$ and $m_i \in \mathbb{N}$ $(i \in I)$ such that (w_i) with multiplicities (m_i) is a tight frame of length M, δ an integer of $K(P)$ with $\delta\overline{\delta} = N$, and $x_{(i,k)}$, for $(i,k) \in I \times n$, triples of natural numbers of degree m_i. Let C be a CM*

datum for d and $a \in \Lambda_C$ with $\operatorname{area}(C) = |a|^2/N \cdot M \cdot \sqrt{d}/2$. *Then there is $F \in \mathcal{W}_{\mathrm{f}}(V)$ with the following properties.*

(1) For every $\gamma \in E(P,\mu)^n$, with $G_{(i,k)} = U^{C,m_i}_{y_{(i,k)}} \operatorname{mon}_C(x_{(i,k)})$ and $y_{(i,k)} = -\frac{a}{\overline{\delta}} \sum_\tau \iota_\tau(\gamma_k)\,\overline{\iota_\tau(w_i)}$:

$$\operatorname{Th}_V(\mathfrak{h}_V((\alpha^{-1}\gamma)^\flat)F) = \prod_{(i,k)} G_{(i,k)}(0),$$

$$T^V_c(\mathfrak{h}_V((\alpha^{-1}\gamma)^\flat)F) = \prod_{(i,k)} \operatorname{Tay}(G_{(i,k)})\Big(\sum_\tau \frac{a}{\overline{\delta}\operatorname{asc}(P)}\, c\,\overline{\iota_\tau(w_i)}\, z_{(\tau,k)}\Big)$$

for every $c \in \mathbb{C}$; here $\alpha = \alpha(P,\mu)$, so that $(\alpha^{-1}\gamma)^\flat$ has finite part γ.

(2) For every p-adic place (p,j) and every $x \in \mathbb{A}_{\mathrm{f}}^n$: $|j(F(x^\flat))|_p \le 1$.

(3) F has a vacuum expansion for (δ, N) in the sense of (Q9).

Proof. Put $b = a/\overline{\delta}$ and, for $(i,k) \in I \times n$, let $A_{(i,k)}$ be the linear form

$$A_{(i,k)}(z) = \sum_\tau (b/\operatorname{asc}(P))\,\overline{\iota_\tau(w_i)}\, z_{(\tau,k)}.$$

The hermitian form of C is $H_C(z,z') = \pi \bar z z' / \operatorname{area}(C)$. By the frame identity,

$$\sum_{(i,k)} m_i\, H_C(A_{(i,k)}u, A_{(i,k)}v) = \frac{\pi\,|b|^2 M}{\operatorname{area}(C)\operatorname{asc}(P)^2} \sum_{(\tau,k)} \overline{u_{(\tau,k)}} v_{(\tau,k)} = \sum_{(\tau,k)} \overline{u_{(\tau,k)}} v_{(\tau,k)},$$

because $|b|^2 = |a|^2/N$, $\operatorname{asc}(P)^2 = 2\pi/\sqrt{d}$ and $\operatorname{area}(C) = |a|^2 M\sqrt{d}/(2N)$: the linear forms carry the sum of the Riemann forms of the curve to the standard form. Let $S = \prod_{(i,k)} \operatorname{mon}_C(x_{(i,k)}) \circ A_{(i,k)}$, an entire function. For $\gamma \in \mathfrak{a}(P,\mu)^n$ the form $A_{(i,k)}$ takes at the real image of $\overline{\delta}\gamma$ the value $a\sum_\tau \iota_\tau(\gamma_k)\overline{\iota_\tau(w_i)}$, which lies in Λ_C by Lemma 3.3(b) because $a \in \Lambda_C$ and Λ_C is a module over $\mathcal{O}_{K(P)}$. A monomial section of degree m_i is invariant under the twisted translations U^{C,m_i}_λ, $\lambda \in \Lambda_C$, up to the multiplier of Λ_C (quoted). So S has the transformation law required in (Q9), which gives $F \in \mathcal{W}_{\mathrm{f}}(V)$ with $\Theta_F = S$ and (3). For (1), the theta function of $\mathfrak{h}_V((\alpha^{-1}\gamma)^\flat)F$ is the translate of S by the real image of γ (quoted), that is the product of the functions $G_{(i,k)} \circ A_{(i,k)}$; Lemma 5.1(c) with $\lambda_{c,(i,k)} = c$ times the coefficients of $A_{(i,k)}$ gives both formulas. For (2), a quoted approximation lemma gives γ with $\mathfrak{h}_V(x^\flat)F = \mathfrak{h}_V((\alpha^{-1}\gamma)^\flat)F$, so $F(x^\flat) = \prod G_{(i,k)}(0)$ by (1); and some positive integer multiple of γ lies in $\mathfrak{a}(P,\mu)^n$, so that a multiple of each $y_{(i,k)}$ lies in Λ_C as above. Each factor then has $|j(\,\cdot\,)|_p \le 1$ by (Q7). □

6 Conjugates of jets

Proposition 6.1 (a generating vector and its conjugates)**.** *Let $P = (N_0, d)$ be parameters. There is a natural number C such that for every natural number μ there is a family $(B_\sigma)_{\sigma \in \mathrm{Aut}(\mathbb{C}/K(P))}$ of finite adeles of $E(P,\mu)$ with the following properties, for every finite set n and every standard hermitian space V over $E(P,\mu)$ with index set n.*

(i) There is $c \in \mathbb{C}$, $c \neq 0$, such that $|j(c \cdot \mathrm{vac}_V(x^\flat))|_p \leq 1$ for every p-adic place (p,j) and every $x \in \mathbb{A}_{\mathrm{f}}^n$, and $|\sigma(c \cdot \mathrm{vac}_V(x^\flat))| \leq \exp(C\, N_1(P,\mu)^2)^{|n|}$ for every $\sigma \in \mathrm{Aut}(\mathbb{C}/K(P))$ and every $x \in \mathbb{A}_{\mathrm{f}}^n$.

(ii) There is $F \in \mathcal{W}_{\mathrm{f}}(V)$ with $\mathrm{Th}_V(F) = 1$ such that $\mathcal{W}_{\mathrm{f}}(V)$ is contained in the span over $\mathbb{C}$ of the vectors $\mathfrak{h}_V(x^\flat)F$, $x \in \mathbb{A}_{\mathrm{f}}^n$, and such that for every $\sigma \in \mathrm{Aut}(\mathbb{C}/K(P))$ there are $t \in \mathbb{C}$ and $F' \in \mathcal{W}_{\mathrm{f}}(V)$ with $|t|^2 = \Omega(P,\mu)^{-1}$ and, for every $x \in \mathbb{A}_{\mathrm{f}}^n$: applying σ to the coefficients of $T^V_{\mathrm{per}(P,\mu)}(\mathfrak{h}_V(x^\flat)F)$ gives $T^V_t(\mathfrak{h}_V((B_\sigma x)^\flat)F')$ with every variable $z_{(\tau,i)}$ replaced by $z_{(\mathrm{perm}_\mu(\sigma)^{-1}\tau,i)}$.

The least such C is not asked for; the formal text fixes one by choice, written $C_{\mathrm{gen}}(P)$ below.

Proof. The constant. By (Q4) the invariant a_1 of $\mathcal{E}(P)$ is algebraic: its image under every field isomorphism of $\mathbb{C}$ onto an algebraic closure of $\mathbb{Q}_2$ has absolute value at most 1. Let g be its minimal polynomial and A_0 the finite set of the roots of g that are invariants of CM data for d; for $\alpha \in A_0$ let C_α be the chosen datum with invariant α (Background 3). The absolute values of all twisted translates of the theta function of one datum form a compact set (quoted: sections of an Appell–Humbert datum), so they are bounded by one number M_0 for the finitely many data C_α, $\alpha \in A_0$. Put $C = \lceil M_0 \rceil + 4$. Let $\sigma \in \mathrm{Aut}(\mathbb{C}/K(P))$. Then $\sigma(a_1) \in A_0$, and the conjugate datum $\sigma\mathcal{E}(P) = C_{\sigma(a_1)}$ is one of these data: this is why the conjugate datum is defined through the invariant alone. Apply (Q2) to $\mathcal{E}(P)$, whose lattice is $\Omega_0(P)\mathcal{O}_{K(P)}$ (Lemma 3.1(d)): it gives Ω_σ, e_σ, β_σ and the a_S. Let B_σ be the image of β_σ in the finite adeles of $E(P,\mu)$.

The vector F. Let $N = N_1(P,\mu)$ and take the frame $(\varsigma(P,\mu)^i)_{i<N}$ with multiplicity N (Lemma 4.1), written with every vector repeated N times and multiplicity 1; its length is N^2. For an integer $e \geq 1$, Proposition 5.2 applies with $\delta = Ne$, $\delta\overline{\delta} = (Ne)^2$, all triples equal to $(1,0,0)$, and any CM datum with a lattice vector of the right area. For $e = 1$, the datum $\mathcal{E}(P)$ and $a = \Omega_0(P)$ (the area of $\mathcal{E}(P)$ is $|\Omega_0(P)|^2\sqrt{d}/2$ by (Q1)) it gives F with a vacuum expansion $(A, (x_a), m_0)$ for (N, N^2), so that $|A| = (N^2)^{2f|n|} = N^{4f|n|}$, $f = |\mathrm{Pl}(P,\mu)|$. Formula (1) at $\gamma = 0$ gives $\mathrm{Th}_V(F) = 1$. Pairing the vacuum expansion for $\ell = \mathrm{Th}_V$ with vac_V shows that $\langle \mathrm{vac}_V, \mathfrak{h}_V((-x_a)^\flat)F\rangle_V \neq 0$ for some a; the expansion for the linear form $\ell = m_0^{-1}\langle \mathrm{vac}_V, \mathfrak{h}_V((-x_a)^\flat)\cdot\rangle_V$ then reads $c \cdot \mathrm{vac}_V = \sum_{a'} \epsilon_{a'}\mathfrak{h}_V((-x_{a'})^\flat)F$ with $c = |A|\ell(F) \neq 0$ and coefficients $\epsilon_{a'} \in \{0,1\}$ (the pairings of two translates of the vacuum are 0 or 1 here). So $c \cdot \mathrm{vac}_V$ is a sum of at most $|A|$ translates of F. This gives the spanning statement of (ii), since $\mathcal{W}_{\mathrm{f}}(V)$ is spanned by translates of vac_V, and the p-adic bound of (i), by Proposition 5.2(2) and the ultrametric inequality.

The conjugate vector. Fix σ. Apply Proposition 5.2 with $e = e_\sigma$ to the datum $\sigma\mathcal{E}(P)$ and $a = e_\sigma\Omega_\sigma$, whose area condition is that of (Q2); this gives F'. Put

$t = \sigma(s_1(P,\mu)) \cdot \operatorname{asc}(P)/\Omega_\sigma$. Then $|t|^2 = \Omega(P,\mu)^{-1}$: by Lemma 3.1(a), (Q3) and $\operatorname{area}(\sigma\mathcal{E}(P)) = |\Omega_\sigma|^2\sqrt{d}/2$,

$$|t|^2 = \frac{\mathrm{rd}_{E(P,\mu)}}{\sqrt{d}} \cdot \frac{\operatorname{area}(\sigma\mathcal{E}(P))}{\pi\, e^{\mathrm{cs}(d)}\, 2\pi/\sqrt{d}} \cdot \frac{2\pi/\sqrt{d}}{|\Omega_\sigma|^2} = \frac{\mathrm{rd}_{E(P,\mu)}}{2\pi\, e^{\mathrm{cs}(d)}}.$$

The jet identity. Both sides are locally constant in x (quoted: $x \mapsto \mathfrak{h}_V(x^\flat)F$ is locally constant for $F \in \mathcal{W}_{\mathrm{f}}(V)$), and the vectors $\alpha^{-1}\gamma$, $\gamma \in E(P,\mu)^n$, are dense; so let $x = \alpha^{-1}\gamma$. Because β_σ is a cluster point of the a_S, there is a finite S containing the numbers $x_{i,k} = -\operatorname{Tr}_{E(P,\mu)/K(P)}(\gamma_k\overline{\varsigma(P,\mu)^i})/N$ with $\mathfrak{h}_V((B_\sigma x)^\flat)F' = \mathfrak{h}_V((a_S x)^\flat)F'$. By Proposition 5.2(1) and Lemma 3.3(a) the two jet series are products over (i,k) of

$$\operatorname{Tay}(U^{\mathcal{E}(P),1}_{x_{i,k}\Omega_0(P)}\theta_{\mathcal{E}(P)})\Big(\sum_\tau \frac{\operatorname{per}(P,\mu)\,\Omega_0(P)}{N\operatorname{asc}(P)}\overline{\iota_\tau(\varsigma(P,\mu)^i)}z_{(\tau,k)}\Big) \quad \text{and}$$
$$\operatorname{Tay}(U^{\sigma\mathcal{E}(P),1}_{x_{i,k}\Omega_\sigma a_S}\theta_{\sigma\mathcal{E}(P)})\Big(\sum_\tau \frac{t\,\Omega_\sigma}{N\operatorname{asc}(P)}\overline{\iota_\tau(\varsigma(P,\mu)^i)}z_{(\tau,k)}\Big).$$

The one-variable series correspond under σ by (Q2). The linear forms correspond after the renaming of the places: $\operatorname{per}(P,\mu)\Omega_0(P)/\operatorname{asc}(P) = s_1(P,\mu)$ and $t\Omega_\sigma/\operatorname{asc}(P) = \sigma(s_1(P,\mu))$, and $\sigma(\overline{\iota_\tau(w)}) = \overline{\iota_{\mathrm{perm}_\mu(\sigma)(\tau)}(w)}$ by (I5).

The conjugate bound of (i). $\sigma(c\mathrm{vac}_V(x^\flat))$ is a sum of at most $|A| = N^{4f|n|}$ numbers $\sigma\operatorname{Th}_V(\mathfrak{h}_V(x'^\flat)F)$. Each is the constant term of a jet series of a translate of F, hence by the jet identity the constant term of one of F', which by Proposition 5.2(1) is a product of $N^2|n|$ values of twisted translates of the theta function of $\sigma\mathcal{E}(P)$. As $\sigma\mathcal{E}(P)$ is one of the data C_α, $\alpha \in A_0$, each value is at most $M_0 \le e^{M_0}$. With $f \le N$ and $\log N \le N$,

$$N^{4f|n|}\, e^{M_0 N^2|n|} \;\le\; \exp\big((M_0+4)N^2|n|\big) \;\le\; \exp\big((\lceil M_0\rceil+4)N^2\big)^{|n|};$$

the summand 4 of the constant pays for the number of terms. □

LEAN `Parameters.exists_isJetConjugate_generator` · quoted: `IsAppellHumbert.isCompact_range_norm_thetaShift`, `Space.isLocallyConstant_rho_finVec`, `denseRange_finiteImage`

Lemma 6.2 (the scaled vacuum)**.** *Let $P = (N_0, d)$ be parameters and μ a natural number.*

(a) $\operatorname{vsc}(P,\mu) \neq 0$.

Let further n be a finite set and V a standard hermitian space over $E(P,\mu)$ with index set n.

(b) For every $x \in \mathbb{A}_{\mathrm{f}}^n$: $\theta^\circ_V(x^\flat) = \prod_{i\in n}\operatorname{vsc}(P,\mu)\cdot\operatorname{vac}_{V_1}((x_i)^\flat)$, where V_1 is the standard space of rank one.

(c) For every $x \in \mathbb{A}_{\mathrm{f}}^n$ and every $\sigma \in \operatorname{Aut}(\mathbb{C}/K(P))$ we have the bound $|\sigma(\theta^\circ_V(x^\flat))| \le \exp(C_{\mathrm{gen}}(P)\,N_1(P,\mu)^2)^{|n|}$.

(d) For every $x \in \mathbb{A}_{\mathrm{f}}^n$ and every p-adic place (p,j): $|j(\theta^\circ_V(x^\flat))|_p \le 1$.

(e) Let $f \in \mathcal{S}(V)$ and let M be a real number with $|f(x^\flat)| \le M$ for every $x \in \mathbb{A}_{\mathrm{f}}^n$. Then $|\langle f, f\rangle_V| \le M^2$.

(f) There is $x \in \mathbb{A}_{\mathrm{f}}^n$ with $\theta^\circ_V(x^\flat) \neq 0$.

Proof. (a) is part of the choice. (b) For a standard space the vacuum is the product of the rank-one vacua of the coordinates (quoted). (c) and (d) follow from (b) and Proposition 6.1(i) for rank one, factor by factor. (e) Quoted: $\langle f, f\rangle_V$ is the mean of $|f|^2$ over a compact quotient of $\mathbb{A}^n$. The set of points where $|f| \le M$ is closed, and it contains a dense set: by the translation formula for the values of f and the density of $E(P,\mu)$ in its archimedean completion, the value of f at a point of a dense set is a value $f(x^\flat)$ (V is standard, so its adelic point is 1). (f) Otherwise (e) with $M = 0$ would give $\langle \mathrm{vac}_V, \mathrm{vac}_V\rangle_V = 0$. □

Proof of Theorem B. Let F, F', t, $B = B_\sigma$ be as in Proposition 6.1(ii) for V and σ, and write $\Theta \mapsto \Theta^{[\sigma]}$ for the renaming $z_{(\tau,i)} \mapsto z_{(\mathrm{perm}_\mu(\sigma)^{-1}\tau,i)}$. The map $g \mapsto (T_t^V g)^{[\sigma]}$ is injective on $\mathcal{W}_{\mathrm{f}}(V)$ by Lemma 5.1(b), as $t \neq 0$. Let L be a left inverse of it, composed with the σ-semilinear map $f \mapsto \sigma(T^V_{\mathrm{per}(P,\mu)} f)$. By the jet identity of Proposition 6.1,

$$L(\mathfrak{h}_V(x^\flat)F) = \mathfrak{h}_V((Bx)^\flat)F' \qquad (x \in \mathbb{A}_{\mathrm{f}}^n). \tag{3}$$

Since $\mathcal{W}_{\mathrm{f}}(V)$ is spanned by the vectors $\mathfrak{h}_V(x^\flat)F$ and Heisenberg operators compose up to roots of unity given by ψ_0, (3) gives (ii) for all $f \in \mathcal{W}_{\mathrm{f}}(V)$ and the rule $L(\mathfrak{h}_V(x^\flat)f) = \mathfrak{h}_V((Bx)^\flat)(Lf)$, provided that $\sigma(\psi_0(z)) = \psi_0(B\overline{B}z)$ for all $z \in \mathbb{A}_{\mathrm{f}}$. This identity is read off the jet identity in rank one. Let V_1 be the standard space of rank one and F_1, F_1' its vectors of Proposition 6.1(ii) for σ; the adele B is the same. The maps $x \mapsto \mathfrak{h}_{V_1}(x^\flat)F_1$ and $x \mapsto \mathfrak{h}_{V_1}(x^\flat)F_1'$ are locally constant on $\mathbb{A}_{\mathrm{f}}$ (quoted), so there is a natural number $N' \neq 0$ with

$$\mathfrak{h}_{V_1}((N')^\flat)F_1 = F_1 \qquad \text{and} \qquad \mathfrak{h}_{V_1}((N'B)^\flat)F_1' = F_1'$$

(quoted: a neighbourhood of 0 in $\mathbb{A}_{\mathrm{f}}$ contains $N'v$ for all v in the compact set $\{1, B\}$, for a suitable N'). Let $z \in \mathbb{A}_{\mathrm{f}}$ and write $z = N'x$, which is possible because N' is a unit of $\mathbb{A}_{\mathrm{f}}$. By (1),

$$\mathfrak{h}_{V_1}((2x)^\flat)F_1 = \mathfrak{h}_{V_1}((2x)^\flat)\mathfrak{h}_{V_1}((N')^\flat)F_1 = \psi_0(z)\cdot \mathfrak{h}_{V_1}((2x+N')^\flat)F_1,$$
$$\mathfrak{h}_{V_1}((2Bx)^\flat)F_1' = \mathfrak{h}_{V_1}((2Bx)^\flat)\mathfrak{h}_{V_1}((N'B)^\flat)F_1' = \psi_0(B\overline{B}z)\cdot \mathfrak{h}_{V_1}((B(2x+N'))^\flat)F_1'.$$

Let T be the series

$$T = \sigma(T^{V_1}_{\mathrm{per}(P,\mu)}(\mathfrak{h}_{V_1}((2x+N')^\flat)F_1)) = (T_t^{V_1}(\mathfrak{h}_{V_1}((B(2x+N'))^\flat)F_1'))^{[\sigma]},$$

the two expressions being equal by the jet identity at $2x + N'$. The jet identity at $2x$ then reads $\sigma(\psi_0(z))\cdot T = \psi_0(B\overline{B}z)\cdot T$. Here $T \neq 0$ by Lemma 5.1(b): the scale $\mathrm{per}(P,\mu)$ is not zero (Lemma 3.1(c)), and $\mathfrak{h}_{V_1}((2x+N')^\flat)F_1 \neq 0$, because Heisenberg operators are invertible and $\mathrm{Th}_{V_1}(F_1) = 1$. Hence $\sigma(\psi_0(z)) = \psi_0(B\overline{B}z)$. Now (Q10) applies: it gives c, z, (iii) and (v), and that B is a unit. Taking constant terms in (ii) for $f = \mathfrak{h}_V(x^\flat)\theta_V^\circ$ shows $\mathrm{Th}_V(L(\mathfrak{h}_V(x^\flat)\theta_V^\circ)) = \sigma(\theta_V^\circ(x^\flat))$, which is nonzero for some x by Lemma 6.2(f); as $L\theta_V^\circ$ is a multiple of $c\,\omega_V(1, z1_n)\mathrm{vac}_V$, this forces $c \neq 0$. (i) is Proposition 6.1.

The bound (iv). By (iii) and the translation rule, $L(\mathfrak{h}_V(x^\flat)\omega_V(1,g)\theta_V^\circ)$ is a number of absolute value 1 times $\mathfrak{h}_V((Bx)^\flat)\omega_V(1,g)L\theta_V^\circ$, and $L\theta_V^\circ = c'\omega_V(1, z1_n)\mathrm{vac}_V$ for

a constant c'. The values of $L\theta^\circ_V$ at the points $(Bx)^\flat$ are the numbers $\sigma(\theta^\circ_V(x^\flat))$, bounded by $\exp(C_{\mathrm{gen}}(P)N_1(P,\mu)^2)^{|n|}$ (Lemma 6.2(c)); since B is a unit these are all its values at finite vectors, and Lemma 6.2(e) bounds $|c'|$ by the same number. It remains to bound a translated vacuum $\omega_V(1,g')\mathrm{vac}_V$ at an arbitrary adelic point. Its value is an inner product with a translate of the vacuum, which a quoted series expresses as a sum of Gaussian terms over the points of a lattice in $\mathbb{C}^{\mathrm{Pl}(P,\mu)\times n}$: the vectors $\gamma \in E(P,\mu)^n$ whose coordinates at the point g' lie in $\alpha(P,\mu)\widehat{\mathcal{O}}$. Since $N_1(P,\mu)\alpha(P,\mu) \in \widehat{\mathcal{O}}$ (I1), the difference of two such vectors, multiplied by $N_1(P,\mu)$, has integral coordinates at g': it lies in the lattice of the space V moved by g'. A non-zero vector ξ of that lattice has length at least 1 (quoted): the value of the hermitian form at (ξ,ξ) is an integer of $E(P,\mu)$ whose absolute values at the infinite places are at most the squared length of ξ; an integer with all these absolute values less than 1 is 0, and the form is definite. So the points $N_1(P,\mu)\gamma$ have mutual distances at least 1, and a packing estimate for separated points (quoted), applied to them, bounds the sum by exp of a quadratic polynomial in $f|n| \le N_1(P,\mu)|n|$ with coefficients controlled by $N_1(P,\mu)$ and $\sqrt{d}$. The constant $C(P)$ of unit 152 is $C_{\mathrm{gen}}(P) + 2d + 6$ plus non-negative terms, and the product of the two bounds is at most $\exp(C(P)(N_1(P,\mu)|n|+1)^2)$. I did not replay the last estimate line by line; see §12. □

Lemma 6.3 (names are admissible combinations)**.** *Let E be a field with a CM type and Weil data, n a finite set, V a hermitian space over E with index set n, and $\mathfrak{m}$ a modulus of E with residue ring $\mathcal{O}_E/\mathfrak{m}$. Let Ψ be a complex function on $(\mathcal{O}_E/\mathfrak{m})^n$, b a proposition, B a real number, $u,v \in \mathcal{S}(V)$, g an integer of E and q a natural number. Suppose that $g\,q \in \mathfrak{m}$; that every value $\Psi(x)$ is integral away from q (that is, $|j'(\Psi(x))|_\ell \le 1$ for every prime $\ell \nmid q$ and every ring homomorphism $j' : \mathbb{C} \to \mathbb{C}_\ell$); that, if b holds, $\sum_x |\sigma(\Psi(x))| \le B$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$; and that $P^{\mathfrak{m}}u = v$. Let η be a finite adele of E with $\eta q \equiv 0$ modulo $\mathfrak{m}$ (by default the image of g). Then the vector $\mathrm{name}_{V,\mathfrak{m}}(\tilde{\Psi})\,u$, where $\tilde{\Psi}$ is the function on $\mathbb{A}_{\mathrm{f}}^n$ that is Ψ of the reduction at the vectors integral at the primes of $\mathfrak{m}$ and 0 elsewhere, is a finite combination $\sum_x r(x)\,\mathfrak{h}^{\mathrm{f}}_V(x)v$ in which every x has $\overline{\eta}\,x_i$ integral at all places not dividing q, every $\mathrm{N}(g)^{|n|}r(x)$ is integral away from q, and, if b holds, $\sum_x |\sigma(r(x))| \le B$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$. (In the terms of unit 141: an admissible combination of the $\mathfrak{h}^{\mathrm{f}}_V(x)v$ with support, denominator $\mathrm{N}(g)^{|n|}$ and size B as said.)*

Proof. By Fourier inversion on the finite group $(\mathcal{O}_E/\mathfrak{m})^n$, with a primitive additive character $\psi_{\mathfrak{m}}$,

$$\Psi = \sum_a \Psi(a) \sum_b \frac{\psi_{\mathfrak{m}}(-a\cdot b)}{|\mathcal{O}_E/\mathfrak{m}|^n}\,\psi_{\mathfrak{m}}(\,\cdot\, b).$$

Quoted: the name of the character $x \mapsto \psi_{\mathfrak{m}}(x\cdot b)$, applied to u, is a root of unity times $\mathfrak{h}^{\mathrm{f}}_V(x_b)P^{\mathfrak{m}}u = \mathfrak{h}^{\mathrm{f}}_V(x_b)v$ for a lift x_b of b. The outer coefficients $\Psi(a)$ are integral away from q and of size B; the inner ones are roots of unity divided by $|\mathcal{O}_E/\mathfrak{m}|^n$, and $\mathrm{N}(g)^{|n|}/|\mathcal{O}_E/\mathfrak{m}|^n$ is integral away from q because $\mathrm{N}(\mathfrak{m})$ divides $\mathrm{N}(gq)$. The composition rule for admissible combinations (unit 141) gives the result; the lifts x_b can be taken with $\overline{\eta}x_b$ integral away from q since $\eta q \in \mathfrak{m}\widehat{\mathcal{O}}$ and q is a unit there. □

7 Standard data, integral jets, gauges

Lemma 7.1 (stability of the standard data). *Let $P = (N_0, d)$ be parameters, μ a natural number and n a finite set.*

(a) For every integer δ of $K(P)$ and every set S of finite places: $\widehat{\mathcal{O}}^n \subset \mathrm{Lat}(\delta; S)$.

Let further V be a hermitian space over $E(P,\mu)$ with index set n, (p, j) a p-adic place and δ an integer of $K(P)$.

(b) If $x \in \mathrm{Lat}(\delta; \{w : w \mid p\})$ and $f \in \mathrm{Std}_\delta(V)$, then $\mathfrak{h}^{\mathrm{f}}_V(x) f \in \mathrm{Std}_\delta(V)$.
(c) If $g \in \mathrm{U}_n(\mathbb{A}_{\mathrm{f}})$ is integral above p and $f \in \mathrm{Std}_\delta(V)$, then $\omega_V(1, g) f \in \mathrm{Std}_\delta(V)$.
(d) For a normed field R, a multiplicative map $\iota\colon \mathbb{C} \to R$ and $z \in \mathbb{A}_{\mathrm{f}}$: $|\iota(\psi_0(z))| = 1$.
(e) Let n' be a finite set and a, b characters of $\mathrm{U}(1)$ over $E(P,\mu)$ that have weights e, e_a and tame parts ψ, ψ'. If $f \in \mathrm{Std}_\delta(\mathrm{Hom}(I_n, I_{n'}))$, and $g \in \mathrm{U}_n(\mathbb{A}_{\mathrm{f}})$, $h \in \mathrm{U}_{n'}(\mathbb{A}_{\mathrm{f}})$ are integral above p, then $\omega_{a,b}((1,g),(1,h)) f \in \mathrm{Std}_\delta(\mathrm{Hom}(I_n, I_{n'}))$.

Proof. (a) δ is integral. (d) $\psi_0(z)$ is a root of unity. (b) It suffices to treat a generator $f = \mathfrak{h}^{\mathrm{f}}_V(y)\theta^\circ_V$; then $\mathfrak{h}^{\mathrm{f}}_V(x) f$ is $\psi_0(\cdot)\mathfrak{h}^{\mathrm{f}}_V(x+y)\theta^\circ_V$, the scalar lies in O_j by (d), and $x + y \in \mathrm{Lat}(\delta; \{w \mid p\})$. (c) Multiplication by g preserves $\mathrm{Lat}(\delta; \{w \mid p\})$. Quoted: $\omega_V(1,g)\mathrm{vac}_V$ is $\Delta_{\mathrm{f}}(g)$, of absolute value 1 at j, times a finite sum of vectors $\mathfrak{h}^{\mathrm{f}}_V(y)\mathrm{vac}_V$ with $y \in \widehat{\mathcal{O}}^n$; so $\omega_V(1,g)\mathfrak{h}^{\mathrm{f}}_V(x)\theta^\circ_V$, which is $\mathfrak{h}^{\mathrm{f}}_V(gx)\omega_V(1,g)\theta^\circ_V$, lies in $\mathrm{Std}_\delta(V)$ by (a) and (b). (e) The action is a value of the characters, of absolute value 1 at j on elements integral above p (quoted), times $\omega_{\mathrm{Hom}(I_n, I_{n'})}$ of an element integral above p; use (c). □

Proposition 7.2 (from theta products to jets of standard data). *Let $P = (N_0, d)$ be parameters, μ a natural number, n a finite set, V a standard hermitian space over $E(P,\mu)$ with index set n, (p, j) a p-adic place, δ an integer of $K(P)$ and $f \in \mathrm{Std}_\delta(V)$. Let $c \in \mathbb{C}$, let L be a $\mathbb{C}$-linear form on the power series in the variables $z_{(\tau,i)}$, $(\tau, i) \in \mathrm{Pl}(P,\mu) \times n$, and let $r \geq 0$ be a real number. Suppose that $|j(L(\Theta))|_p \leq r$ for every power series Θ over $\mathbb{C}$ whose image under j lies in $\mathrm{ThProd}_{P,\mu}(\delta, |j(c \cdot s_1(P,\mu))|_p; n)$. Then*

$$|j(L(T^V_{c \cdot \mathrm{per}(P,\mu)} f))|_p \leq r.$$

Proof. The set of $f \in \mathcal{S}(V)$ with the asserted bound is an O_j-submodule, so let $f = \mathfrak{h}^{\mathrm{f}}_V(x)\theta^\circ_V$ with $x \in \mathrm{Lat}(\delta; \{w \mid p\})$. Put $M = p\,(d\,N_1(P,\mu))^6 + 1$, prime to p. By Theorem A (with $c_* = 0$) there is a tight frame of length M^2; repeat its vectors so that the multiplicities are 1. Proposition 5.2 with $N = M^2$, $\delta_0 = M$, triples $(1,0,0)$, the datum $\mathcal{E}(P)$ and $a = \Omega_0(P)$ gives F with $\mathrm{Th}_V(F) = 1$ and a vacuum expansion $(A, (y_a), m_0)$ with My_a integral. Applied to the linear form $\mathrm{vsc}(P,\mu)^{|n|}|A|^{-1}\,\mathrm{Th}_V$ it writes θ°_V as a combination of the vectors $\mathfrak{h}_V((-y_a)^\flat)F$ whose coefficients are values of θ°_V, in O_j by Lemma 6.2(d), times $m_0/|A|$, where $|A|$ is a power of M and so a unit at j. Hence it suffices to bound $L(T^V_{\mathrm{cper}(P,\mu)} f')$ for $f' = \mathfrak{h}_V((x - y_a)^\flat)F$. Approximate:

$f' = \mathfrak{h}_V((\alpha^{-1}\gamma)^\flat)F$ with $\gamma \in E(P,\mu)^n$. By Proposition 5.2(1), $T^V_{\mathrm{cper}(P,\mu)} f'$ is a product of Taylor series of translates $U_y^{\mathcal{E}(P),1}\theta_{\mathcal{E}(P)}$ at the linear forms with coefficients $b\,\overline{\iota_\tau(w_i)}$, where $b = \Omega_0(P)\,c\,\mathrm{per}(P,\mu)/(M\mathrm{asc}(P)) = c\,s_1(P,\mu)/M$, so $|j(b)|_p = |j(cs_1(P,\mu))|_p$. Its image under j lies in $\mathrm{ThProd}_{P,\mu}(\delta, |j(cs_1(P,\mu))|_p; n)$: the frame has length M^2, prime to p; and for the lattice condition choose a positive integer m' with $m'\delta M\gamma \in \mathfrak{a}(P,\mu)^n$, write $m' = p^k m''$ with $p \nmid m''$, and take the integer $m''M^2$, prime to p. Indeed $\alpha(P,\mu)^{-1}\delta M\gamma$ is integral at the places above p: the approximation can be taken so that $\alpha(P,\mu)^{-1}\gamma$ differs from $x - y_a$ by an integral vector, and δx and My_a are integral at these places. At the other places p^k is a unit, so $m'\delta M\gamma \in \mathfrak{a}(P,\mu)^n$ gives the integrality of $\alpha(P,\mu)^{-1}m''\delta M\gamma$ there. Hence $m''\delta M\gamma \in \mathfrak{a}(P,\mu)^n$, and the translation vectors, $-\Omega_0(P)/M$ times $\sum_\tau \iota_\tau(\gamma_k)\overline{\iota_\tau(w_i)}$, are carried into $\Omega_0(P)\mathcal{O}_{K(P)} = \Lambda_{\mathcal{E}(P)}$ by $m''M^2\delta$ (Lemma 3.3(b)). The hypothesis gives the bound. □

LEAN `Parameters.norm_jetSeries_le`

Lemma 7.3 (jets of products of torsion translates)**.** *Let d be a prime number $\equiv 7 \bmod 8$, C a CM datum for d, (p,j) a p-adic place, I and S finite sets, $c_{i,x} \in \mathbb{C}_p$ for $(i,x) \in I \times S$, and $\delta \in \mathcal{O}_d$ with $\delta \neq 0$. Suppose that $|j(\bar\delta)^{-1}c_{i,x}/d|_p \le 1$ for all i, x, and let $y_i \in \mathbb{C}$ with $\delta y_i \in \Lambda_C$ for all $i \in I$. Then for every polynomial Q in the variables z_x, $x \in S$, with coefficients in O_j, the jet along $j(Q)$ of the series*

$$\prod_{i\in I} \mathrm{Tay}_j(U^{C,1}_{y_i}\theta_C)\Big(\sum_{x\in S} c_{i,x}z_x\Big)$$

lies in $\mathfrak{o}_p$.

Proof. Let L, L_2 be as in (Q6) and $\ell_i = j(\bar\delta)^{-1}\sum_x c_{i,x}z_x$. Let $\mathcal{R}$ be the $\mathfrak{o}_p$-subalgebra of $\mathbb{C}_p[[z]]$ generated by the series $G(\ell_i)$ with $i \in I$ and $G \in \mathfrak{o}_p[[\varphi_C]] \cup \{L', \exp(-L)\}$. *Every element of $\mathcal{R}$ has constant term in $\mathfrak{o}_p$, and $\mathcal{R}$ is stable under the $\partial/\partial z_x$.* By the Leibniz rule it suffices to check the generators. By the chain rule $\partial_x(G(\ell_i)) = (dG')(\ell_i)\cdot c_{i,x}/(j(\bar\delta)d)$, and the last factor lies in $\mathfrak{o}_p$. If $G \in \mathfrak{o}_p[[\varphi_C]]$ then $dG' \in \mathfrak{o}_p[[\varphi_C]]$ by (Q5). If $G = L'$ then $dL'' = dL_2 + d\,\mathrm{Tay}_j(\xi_C) \in \mathfrak{o}_p[[\varphi_C]]$, because $dL_2 = -j(\sqrt{-d})\cdot j(\sqrt{-d})L_2 \in \mathfrak{o}_p$ by (Q6). If $G = \exp(-L)$ then $G' = -L'G$. The constant terms are integral ($L'(0) = 0$, $\exp(-L)(0) = 1$, (Q5)). It follows by induction on the degree of Q that jets of elements of $\mathcal{R}$ along $j(Q)$ lie in $\mathfrak{o}_p$: the jet along z_xQ is the jet of $\partial_x F$ along Q. Finally each factor of the product lies in $\mathcal{R}$: by (Q7), $\mathrm{Tay}_j(U^{C,1}_{y_i}\theta_C)(j(\bar\delta)X) = \exp(-L)^{\delta\bar\delta}u_i$ with $u_i \in \mathfrak{o}_p[[\varphi_C]]$, and the factor is this series at $X = \ell_i$. □

LEAN `CMLattice.jet_theta_prod_integral`

Proof of Theorem C. Apply Proposition 7.2 with $c = \bar\delta d$, $L = \mathrm{jet}_{Q'}(\,\cdot\,)$ and $r = 1$. Let Θ be a series whose image under j lies in $\mathrm{ThProd}_{P,\mu}(\delta, |j(\bar\delta d\,s_1(P,\mu))|_p; n)$, with frame (w_i), numbers n_0, b and translation vectors $y_{(i,k)}$. Then $j(\mathrm{jet}_{Q'}(\Theta))$ is the jet along $j(Q)$ of a product as in Lemma 7.3, for the datum $\mathcal{E}(P)$, the integer $n_0\delta$ (so that $n_0\delta\,y_{(i,k)} \in \Lambda_{\mathcal{E}(P)}$) and the coefficients $c_{(i,k),(\tau,k')} = [k = k']\,j(b\,\overline{\iota_\tau(w_i)})$. The hypothesis of the lemma holds: $|j(b)|_p = |j(\bar\delta d s_1(P,\mu))|_p$, n_0 is a unit at j, and $|j(s_1(P,\mu)\overline{\iota_\tau(w_i)})|_p \le 1$ by Lemma 3.2(c), so $|j(n_0\bar\delta)^{-1}j(b\,\overline{\iota_\tau(w_i)})/d|_p \le 1$. □

LEAN `Parameters.norm_jet_jetSeries_le_one`

Proposition 7.4 (one theta lift and the gauges)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number, n, n' finite sets and (p,j) a p-adic place.*

(a) Let k be a kernel as in Definition 2.3 with data in $\mathcal{D}$, $\Phi \in \mathcal{D}$, $d_1 \in \mathrm{U}_n(\mathbb{A}_{\mathrm{f}})$, $d_2 \in \mathrm{U}_{n'}(\mathbb{A}_{\mathrm{f}})$, $z \in \mathbb{C}$ and c, c' real numbers. If $\Phi \in \mathrm{Raise}_k(d_1, d_2; c)$ and $|j(z)|_p \cdot c \le c'$, then $z\Phi \in \mathrm{Raise}_k(d_1, d_2; c')$.

Let further $\varkappa$ be a lift weight for n, n', e_b, e; a, b characters of $\mathrm{U}(1)$ over $E(P,\mu)$ with weights e_a, e_b and tame parts ψ, ψ'; K a level; and $c \in \mathbb{C}$.

(b) Let $k = \mathrm{k}_{\varkappa}(c; a, b; K)$, δ an integer of $K(P)$ and $\Psi \in \mathcal{W}_{\mathrm{f}}(\mathrm{Hom}(I_n, I_{n'}))$ with $\Psi \in \mathrm{Std}_{\delta}(\mathrm{Hom}(I_n, I_{n'}))$. Let $x, y \in \mathrm{U}_{n'}(\mathbb{A}_{\mathrm{f}})$ be integral above p, $d_0 \in \mathrm{U}_{n'}(\mathbb{A}_{\mathrm{f}})$, and $u_\tau \in \mathbb{C}_p^{n'}$ ($\tau \in \mathrm{Pl}(P,\mu)$) such that the image of the matrix of d_0 under $\hat{\jmath}_\tau$ is the diagonal matrix of u_τ, for every τ. Let B be a real number such that for every $f \in \mathrm{Std}_{\delta}(\mathrm{Hom}(I_n, I_{n'}))$ and all Weyl indices i', i

$$\prod_{\tau} \Big(\prod_{b \in n'} |u_\tau(b)|_p \Big)^{e_{a,\tau}} \prod_{h,l,s} |u_\tau(i'_\tau(h,l,s))|_p \;\cdot\; |j(\mathrm{SJ}_{\varkappa}(T_c^{\mathrm{Hom}(I_n, I_{n'})} f)_{i',i})|_p \;\le\; B.$$

Then $\omega_k(1, x\, d_0\, y)\Psi \in \mathrm{Raise}_k(1, 1; B)$.

(c) Let $k = \mathrm{k}_{\varkappa}(c \cdot \mathrm{per}(P,\mu); a, b; K)$, δ an integer of $K(P)$ with $\delta \neq 0$, and $\Phi \in \mathcal{W}_{\mathrm{f}}(\mathrm{Hom}(I_n, I_{n'}))$ with $\Phi \in \mathrm{Std}_{\delta}(\mathrm{Hom}(I_n, I_{n'}))$. Then

$$\Phi \in \mathrm{Raise}_k(1, 1; (|j(c)|_p / |j(\bar{\delta} d)|_p)^{\mathrm{box}(\varkappa, |n'|)}).$$

(d) Let $k = \mathrm{k}_{\varkappa}(c \cdot \mathrm{per}(P,\mu); a, b; K)$, let $N \neq 0$, d' and M be natural numbers and $f \in \mathcal{W}_{\mathrm{f}}(\mathrm{Hom}(I_n, I_{n'}))$. If $d' f \in \mathrm{Std}_N(\mathrm{Hom}(I_n, I_{n'}))$, $|j(c)|_p \le 1$ and $d' \cdot (N \cdot d)^{\mathrm{box}(\varkappa, |n'|)}$ divides M, then $Mf \in \mathrm{Raise}_k(1, 1; 1)$.

Proof. (a) The gauge is homogeneous: $\mathrm{gauge}_j^{\varkappa, e_a}(g; z\xi) = |j(z)|_p \, \mathrm{gauge}_j^{\varkappa, e_a}(g; \xi)$.

(b) Let $g \in \mathrm{U}_n(\mathbb{A}_{\mathrm{f}})$, $g' \in \mathrm{U}_{n'}(\mathbb{A}_{\mathrm{f}})$ and ξ be given. Write $g = \gamma\, g_0$ and $g' x d_0 = \varepsilon\, h_0\, d_0$ with rational points γ, ε and g_0, h_0 integral above p (Background 5). By the equivariance of the kernel under rational points and the invariance of the gauge under elements integral above p, it is enough to bound the largest coordinate of j applied to $\mathrm{jm}_k(\omega_k(g_0, h_0 d_0 y)\Psi)\, \xi'$, with d_0^{-1} acting in weight $(\varkappa, e_a)$, against the largest coordinate of $j(\xi')$. Now $\omega_k(g_0, h_0 \cdot y)$ with integral elements preserves $\mathrm{Std}_{\delta}(\mathrm{Hom}(I_n, I_{n'}))$ by Lemma 7.1(e), the remaining d_0 acts on the Schur jets through its diagonal images u_τ, which multiply the row i' by the product of the u_τ over the boxes of i'_τ and by the determinants to the power $e_{a,\tau}$, and the entries are bounded by the hypothesis.

(c) Take $x = d_0 = y = 1$, $u_\tau = 1$ in (b). For $f \in \mathrm{Std}_{\delta}(\mathrm{Hom}(I_n, I_{n'}))$ the homogeneity of the Schur jets (Background 5) gives

$$\mathrm{SJ}_{\varkappa}(T^{\mathrm{Hom}(I_n, I_{n'})}_{\mathrm{cper}(P,\mu)} f) = \Big(\frac{c}{\bar{\delta} d} \Big)^{\mathrm{box}(\varkappa, |n'|)} \mathrm{SJ}_{\varkappa}(T^{\mathrm{Hom}(I_n, I_{n'})}_{\bar{\delta} d \,\mathrm{per}(P,\mu)} f),$$

and the entries of the last matrix are jets along polynomials with integral coefficients, so Theorem C applies to the standard space $\mathrm{Hom}(I_n, I_{n'})$.

(d) Write $M = d'(Nd)^{\mathrm{box}(\varkappa, |n'|)} s$. By (c) with $\delta = N$,

$$d' f \in \mathrm{Raise}_k(1, 1; (|j(c)|_p / |j(Nd)|_p)^{\mathrm{box}(\varkappa, |n'|)}),$$

and by (a), multiplying by the integer $(Nd)^{\mathrm{box}(\varkappa, |n'|)} s$ gives the bound $|j(c)|_p^{\mathrm{box}(\varkappa, |n'|)} \le 1$. □

8 The normal form at a prime that does not split

In this section $q = p^\nu$ will be the norm of a prime of $\mathbb{Q}(\sqrt{-d})$ above p: $\nu = 2$ if p is inert and $\nu = 1$ otherwise.

Lemma 8.1 (a valuation bound)**.** *Let p be a prime number and ν, Q natural numbers with $p^\nu = Q+1$. Let x, t, o, J, k be natural numbers with $\nu \neq 0$, $o \leq 1$ and $x+1+QJ = pt+o+Qk$. Then there is a natural number a with $|x+1|_p = p^{-a}$ such that: if $a > 1$ then $p < x+1$; either $a = 0$ or $k \equiv o + J \bmod p$; and $l\,(a-\nu) \leq k+t$ for every natural number $l \leq p$.*

Proof. Let $a = v_p(x+1)$. If $a > 1$ then $x+1 \geq p^2 > p$. If $a \geq 1$, reduce the equation modulo p, where $Q \equiv -1$: $-J \equiv o - k$. If $a > \nu$ then $p^a \leq x+1 \leq pt+1+Qk \leq p^\nu(k+t)+1$, so $k+t > p^{a-\nu}-1$ and therefore $k+t \geq p^{a-\nu} \geq p\,(a-\nu) \geq l\,(a-\nu)$. □

LEAN exists_norm_eq_inv_pow_bounds

Lemma 8.2 (substitution tangent to the identity)**.** *Let p be a prime number, $Z \in \mathbb{C}_p[[X]]$ and m a natural number such that X^{m+1} divides $Z - X$. Then for every natural number $k \leq m+1$ and every $g \in \mathbb{C}_p[[X]]$ the coefficient of X^k in $g(Z)$ is $g_k + g_1 \cdot (Z-X)_k$.*

Proof. Write $Z = X + X^{m+1}W$. Modulo X^{m+2} we have $Z^i \equiv X^i$ for $i \neq 1$ and $Z \equiv X + W_0 X^{m+1}$; so $g(Z) \equiv g + g_1 W_0 X^{m+1}$, and $(Z-X)_k$ is W_0 for $k = m+1$ and 0 for $k \leq m$. □

LEAN coeff_subst_tangent

Lemma 8.3 (only two degrees keep a denominator)**.** *Let $p \geq 13$ be a prime number, $\nu \in \{1,2\}$, Q a natural number with $p^\nu = Q+1$, and $\varpi \in \mathbb{C}_p$ with $|\varpi^Q|_p^2 = p^{-\nu}$ and $\varpi \neq 0$. Let m, n, Z, μ be power series in $\mathbb{C}_p[[X]]$ such that n' and Z' have coefficients in $\mathfrak{o}_p$; $n(0) = 0$; $Z_{l+1} = 0$ for every l not divisible by Q; $Z_{Q+1} = -\varpi^{-Q}$; $m_k = 0$ for $k \leq 2$; $m' = n\,Z'$; and*

$$\mu = \left(\varpi^{p+1}/p\right)^{-1} \cdot [m]_{p+1 \bmod Q}(\varpi X).$$

Then $|\mu_{p+1}|_p \leq 1$, $|\mu_{p+p^\nu}|_p \leq 1$, and the series $\varpi^{-Q}(\mu - \mu_{p+1}X^{p+1} - \mu_{p+p^\nu}X^{p+p^\nu})$ has coefficients in $\mathfrak{o}_p$.

Proof. Only the degrees $k = p+1+QI$, $I \geq 0$, occur in μ, and $\mu_k = p\,\varpi^{QI} m_k$. We show $|\mu_k|_p \leq 1$ for $I \in \{0,1\}$ (the degrees $p+1$ and $p+p^\nu$) and $|\mu_k|_p \leq |\varpi^Q|_p = p^{-\nu/2}$ for $I \geq 2$. From $m' = nZ'$, $n_0 = 0$ and the vanishing of the coefficients of Z,

$$k\,m_k = \sum_{i+1+QJ = p+QI} n_{i+1}\,(QJ+1)\,Z_{QJ+1}, \qquad 0 \leq J \leq I+1.$$

Here $|n_{i+1}|_p \leq p^c$ with $c = v_p(i+1)$, because n' is integral, and $|(QJ+1)Z_{QJ+1}|_p \leq 1$, because Z' is integral. With $a = v_p(k)$ the ultrametric inequality gives

$$\log_p |\mu_k|_p \;\leq\; a - 1 - \tfrac{\nu}{2} I + \max_{(i,J)} c.$$

Lemma 8.1, for $x = p+QI$ ($t = o = 1$, $J = 0$) and for $x = i$ ($t = 1$, $o = 0$), says: $a = 0$ unless $I \equiv 1 \bmod p$; $c = 0$ unless $I \equiv J \bmod p$; and $p\,(a-\nu) \le I+1$, $p\,(c-\nu) \le I+1$. $I = 0$: $a = 0$; either $J = 0$, $i+1 = p$, $c = 1$, or ($\nu = 1$) $J = 1$, $c = 0$: the exponent is at most 0. $I = 1$: $k = p + p^\nu$ and $a = 1$; the terms are $J = 0$ with $i+1 \equiv -1 \bmod p$, $c = 0$; $J = 1$ with $i+1 = p$, $c = 1$, where moreover $|(Q+1)Z_{Q+1}|_p = p^{-\nu/2}$; and ($\nu = 1$) $J = 2$ with $c = 0$. The exponent is at most $\max(-\nu/2,\, 1-\nu,\, -1/2) \le 0$. $2 \le I \le 4$: $a = 0$ since $I \not\equiv 1 \bmod p$; and $c \ge 1$ forces $J = I$, hence $i+1 = p$ and $c = 1$. The exponent is at most $-\nu I/2 \le -\nu/2$. $I \ge 5$: a and c are at most $\nu + (I+1)/p$, so the exponent is at most $2\nu + 2(I+1)/13 - 1 - \nu I/2 \le -\nu/2$; this is where $p \ge 13$ enters. □

LEAN `norm_coeff_le_of_deriv`

Proposition 8.4 (the formal parameter and the logarithm of theta)**.** *Let d be a prime number $\equiv 7 \bmod 8$, C a CM datum for d and (p, j) a p-adic place. Then there are a natural number ν, $\varpi \in \mathbb{C}_p$, $\varpi_0 \in \mathfrak{o}_p$ and power series S, E in one variable with coefficients in $\mathfrak{o}_p$ such that:*

(I) $\nu \ne 0$; $|\varpi|_p = p^{-\varrho_d(p)}$; $p^{-1} \le |\varpi_0|_p < 1$; $S(0) = 0$; $S - S^{p^\nu} = X + \varpi_0 E$; and $T(\varpi X) = \varpi S$ for some $T \in \mathfrak{o}_p[[\varphi_C]]$.

(II) If $\chi_d(p) \ne 1$ and $13 \le p$, there are $u_0, u_1, u_2 \in \mathfrak{o}_p$, a power series R with coefficients in $\mathfrak{o}_p$ and $\psi \in \mathbb{C}_p[[X]]$ such that $|\varpi_0|_p = p^{(\chi_d(p)-1)/2}$; either $\nu = 1$ and $p = d$, or $\nu = 2$, $u_0 = 0$ and $|u_1|_p = 1$; $\psi = u_0X^2 + u_1S^{p+1} + u_2S^{p+p^\nu} + \varpi_0 R$; $\psi(0) = 0$; and for every natural number n prime to p there are $N, \kappa \in \mathbb{C}_p$ with $|N|_p = 1$ and $|\kappa|_p = p^{(1-\chi_d(p))/2 - 1/(p-1)}$ such that for every $y \in \mathbb{C}$ with $ny \in \Lambda_C$ there is a power series V with coefficients in $\mathfrak{o}_p$ with

$$\mathrm{Tay}_j(U_y^{C,1}\theta_C)(\varpi X) = (\exp(\kappa\psi)\cdot V)(NX).$$

Here $\varrho_d(p)$ is $1/(p^2-1)$ if $\chi_d(p) = -1$, $1/(2(p-1))$ if $p = d$, and $1/(p-1)$ if $\chi_d(p) = 1$.

Proof. Step 1: the isogeny. Let $a = \sqrt{-d}$ if $p = d$ and $a = p$ otherwise, and let $q = p^\nu$ be the norm of a prime above p. Then $|j(a)|_p^2 = p^{-s}$ with $s = 1$ if $p = d$ and $s = 2$ otherwise, $\varrho_d(p) = s/(2(q-1))$, and in the two non-split cases $a\overline{a} = q$ is odd.

Step 2: a parameter that commutes with roots of unity. Let $\hat\varphi = \mathrm{Tay}_j(\varphi_C)$ and let $\zeta \in \mathbb{C}_p$ be a primitive root of unity of order $q-1$. By (Q6), $(\zeta^i, \zeta^{i(p+1)}) \in \mathcal{N}_d$, so $\hat\varphi(\zeta^i X) \in \mathfrak{o}_p[[\varphi_C]]$, and $F \mapsto F(\zeta^i X)$ maps $\mathfrak{o}_p[[\varphi_C]]$ to itself. Hence

$$T = [\hat\varphi]_{1 \bmod q-1} = \frac{1}{q-1}\sum_{i<q-1} \zeta^{-i}\hat\varphi(\zeta^i X) \in \mathfrak{o}_p[[\varphi_C]],$$

$q-1$ being a unit of $\mathfrak{o}_p$. As $T(0) = 0$, $T'(0) = 1$, (Q5) applies: let Z be the inverse series of T. From $T(\zeta X) = \zeta T$ we get $Z(\zeta X) = \zeta Z$, so $Z_{l+1} = 0$ unless $q-1$ divides l; in particular X^q divides $Z - X$. Also Z' is integral: $T'(Z)$ is integral with constant term 1 and $T'(Z)Z' = 1$.

Step 3: the scale. The series $g = T(j(a)Z)$ is integral, because $T(j(a)X) \in \mathfrak{o}_p[[\varphi_C]]$ by (Q6), and $Z(g) = j(a)Z$. By Step 2, $T_1 = 1$ and $T_k = 0$ for $1 < k < q$. So Lemma 8.2 gives $g_1 = j(a)$, $g_k = 0$ for $1 < k < q$ and, using $T_q = -Z_q$ (from $T(Z) = X$),

$$g_q = j(a)^q T_q + j(a)Z_q = j(a)(1 - j(a)^{q-1})Z_q, \qquad \text{so that} \quad |g_q|_p = |j(a)|_p \cdot |Z_q|_p.$$

We claim $|g_q|_p = 1$. It is at most 1. In the non-split cases (Q8)(ii) gives a coefficient of absolute value 1 in a degree $\le q$; as $g_0 = 0$, $|g_1|_p = |j(a)|_p < 1$ and $g_k = 0$ for $1 < k < q$, the degree is q. In the split case ($q = p$, $a = p$), if $|g_p|_p < 1$ then $|p\,(Z - X)_p|_p < 1$, and then every $F \in \mathfrak{o}_p[[\varphi_C]]$ has $|(F')_{p-1}|_p = |pF_p|_p < 1$, since by Lemma 8.2 $pF_p = p(F(Z))_p - F_1\,p(Z - X)_p$ with $F(Z)$ integral; by (Q8)(i) this gives $\chi_d(p) \neq 1$, a contradiction. In particular $Z_q \neq 0$. Now choose $\varpi \in \mathbb{C}_p$ with $\varpi^{q-1} = -Z_q^{-1}$ and put $\varpi_0 = \varpi^{q-1}$. Then $|\varpi_0|_p = |Z_q|_p^{-1} = |j(a)|_p = p^{-s/2}$, which is $p^{(\chi_d(p)-1)/2}$ in the non-split cases, and $|\varpi|_p = p^{-s/(2(q-1))} = p^{-\varrho_d(p)}$.

Step 4: the series S. Let $W = \varpi^{-1} Z(\varpi X)$. Its coefficients vanish except in the degrees $1 + (q-1)l$; $W_1 = 1$, $W_q = \varpi_0 Z_q = -1$, and for $l \ge 2$ the coefficient is $\varpi_0^l Z_{1+(q-1)l}$, where $|Z_{1+(q-1)l}|_p \le p^b$, $b = v_p(1 + (q-1)l)$, because Z' is integral. Lemma 8.1 (with $x = (q-1)l$, $t = 0$, $o = 1$, $J = 0$, $k = l$) says that $b = 0$ unless $l \equiv 1 \bmod p$, and that $p\,(b - \nu) \le l$. In each of the three cases $(s, \nu) = (2, 2)$, $(1, 1)$, $(2, 1)$ of Step 1 this gives $2b \le s(l-1)$, that is $|\varpi_0^{l-1} Z_{1+(q-1)l}|_p \le 1$. So $W = X - X^q - \varpi_0 E'$ with E' integral. Let S be the inverse series of W; it is integral with $S(0) = 0$, and $S - S^q = X + \varpi_0 E$ with $E = E'(S)$. By definition $Z(\varpi X) = \varpi W$; substituting S gives $Z(\varpi S) = \varpi X$, and applying T gives $T(\varpi X) = \varpi S$. This proves (I).

Step 5: the logarithm. Assume now $\chi_d(p) \neq 1$ and $p \ge 13$. Let L, L_2 be as in (Q6) and $L_1 = L - \frac{1}{2} L_2 X^2$, so that $L_1'' = \mathrm{Tay}_j(\xi_C)$ and $L_1 = O(X^3)$. Apply Lemma 8.3 with $Q = q - 1$ to $m = L_1(Z)$ and $n = L_1'(Z)$: $m' = nZ'$; $n' = \mathrm{Tay}_j(\xi_C)(Z)\,Z'$ is integral by (Q5); $n(0) = 0$; $m_k = 0$ for $k \le 2$ by Lemma 8.2; and Z has the required coefficients by Steps 2 and 3. With $\kappa_0 = \varpi^{p+1}/p$ this gives $u_1, u_2 \in \mathfrak{o}_p$ and an integral R_0 with

$$\kappa_0^{-1}[L_1(Z)]_{p+1 \bmod q-1}(\varpi X) = u_1 X^{p+1} + u_2 X^{p+q} + \varpi_0 R_0.$$

Put $\psi = \kappa_0^{-1}[L]_{p+1 \bmod q-1}(\varpi X)$. Taking the part in a residue class of degrees commutes with substituting T, because $T(\zeta X) = \zeta T$; and $T(\varpi X) = \varpi S$. Hence $\psi = u_0 X^2 + u_1 S^{p+1} + u_2 S^{p+q} + \varpi_0 R$ with $R = R_0(S)$ and with $u_0 = \kappa_0^{-1} \frac{1}{2} L_2 \varpi^2$ if $2 \equiv p + 1 \bmod q - 1$, that is if $\nu = 1$, and $u_0 = 0$ if $\nu = 2$. In the case $\nu = 1$, $p = d$: $u_0 = \frac{1}{2} L_2\, p/\varpi_0$, and $|u_0|_p = |L_2|_p p^{-1/2} \le 1$ since $|j(\sqrt{-d}) L_2|_p \le 1$ and $|j(\sqrt{-d})|_p = p^{-1/2}$. In the case $\nu = 2$: $p + 1 < q$, so $u_1 = p\,(L_1)_{p+1} = (\mathrm{Tay}_j(\xi_C))_{p-1}/(p+1)$, and $|u_1|_p \ge 1$ by (Q8)(i), whose hypothesis holds because $(Z - X)_p = 0$ (argue as in Step 3). So $|u_1|_p = 1$.

Step 6: torsion translates. Let n be prime to p, $\delta = n(q-1)$, $N = \delta^{-1}$ (a unit of $\mathfrak{o}_p$) and $\kappa = -\delta^2 \kappa_0$; then $|\kappa|_p = p\,|\varpi|_p^{p+1} = p^{(1-\chi_d(p))/2 - 1/(p-1)}$ in both non-split cases. Let $ny \in \Lambda_C$. By (Q7) for the integer δ, $\mathrm{Tay}_j(U_y^{C,1}\theta_C)(\delta X) = \exp(-\delta^2 L) \cdot u$ with $u \in \mathfrak{o}_p[[\varphi_C]]$. By (Q6) for the pairs $(\zeta^{-i}, \zeta^{-i(p+1)})$, rotated by ζ^i, the series $\exp(\zeta^{-i(p+1)} L(\zeta^i X) - L)$ lie in $\mathfrak{o}_p[[\varphi_C]]$; their product over $i < q - 1$ is

$$\Pi = \exp((q-1)([L]_{p+1 \bmod q-1} - L)) \in \mathfrak{o}_p[[\varphi_C]], \quad \text{so that}$$
$$\exp(-\delta^2 L)\, u = \exp(-\delta^2 [L]_{p+1 \bmod q-1}) \cdot \Pi^{n^2(q-1)} u.$$

Let $V = (\Pi^{n^2(q-1)} u)(\varpi X)$. It is integral: $(\Pi^{n^2(q-1)} u)(Z)$ is integral by (Q5), and V is this series at $T(\varpi X) = \varpi S$. Rescaling by ϖ and by N, $\mathrm{Tay}_j(U_y^{C,1}\theta_C)(\varpi X) = (\exp(\kappa\psi) V)(NX)$. □

LEAN CMLattice.exists_formal_parameter

Lemma 8.5 (two computations in characteristic p)**.** *Let p be a prime number, Q a commutative ring of characteristic p and J a finite set.*

(a) Let B, ν be natural numbers and b a proposition such that $\nu = 1$ and b holds, or $\nu = 2$. Let $t_i, L_i \in Q$ $(i \in J)$ with $t_i - t_i^{p^\nu} = L_i$ and $t_i^{p^l} = 0$ for all $l \geq B$. If $\sum_i L_i^{p^e} L_i = 0$ for every e such that e is odd or b holds, then $\sum_i t_i^{p+1} = 0$ and $\sum_i t_i^{p+p^\nu} = 0$.

(b) Let Φ be a finite set, I a set, $r_{v,i} \in Q$ for $(v,i) \in \Phi \times J$, and t_i $(i \in J)$ power series over Q in the variables $X_{(v,c)}$, $(v,c) \in \Phi \times I$, with $t_i(0) = 0$. Let $x \in \Phi$ and $c \in I$ with $t_i - t_i^{p^2} = \sum_v r_{v,i} X_{(v,c)}$ for all i. Then for every exponent β: the coefficient at X^β of $\sum_i t_i^p r_{x,i}$ is nonzero if and only if there are $l \in \mathbb{N}$ and $y \in \Phi$ with $\sum_i r_{y,i}^{p^{2l+1}} r_{x,i} \neq 0$ and $\beta = p^{2l+1} \cdot 1_{(y,c)}$.

Proof. (a) Telescoping, $t_i = \sum_{l<B} L_i^{p^{\nu l}}$. So $\sum_i t_i^p t_i$ and $\sum_i t_i^p t_i^{p^\nu}$ are sums of terms $\sum_i L_i^{p^a} L_i^{p^b}$ with $a - b = 1 + \nu(l - l')$ for the first sum and $a - b = 1 + \nu(l - l' - 1)$ for the second $(l, l' < B)$; these differences are odd if $\nu = 2$. Such a term is the $p^{\min(a,b)}$-th power of $\sum_i L_i^{p^{|a-b|}} L_i$, which vanishes. (b) With $\ell_i = \sum_v r_{v,i} X_{(v,c)}$, telescoping gives $t_i \equiv \sum_{l<B} \ell_i^{p^{2l}}$ up to terms of order $\geq p^{2B}$, and $t_i^p \equiv \sum_l \sum_v r_{v,i}^{p^{2l+1}} X_{(v,c)}^{p^{2l+1}}$. So $\sum_i t_i^p r_{x,i} = \sum_{l,v} (\sum_i r_{v,i}^{p^{2l+1}} r_{x,i}) X_{(v,c)}^{p^{2l+1}}$, and distinct pairs (l,v) give distinct monomials. □

LEAN `sum_pow_eq_zero_of_null` · `coeff_sum_frob_ne_zero_iff` · quoted: `eq_sum_pow_of_sub_pow_eq`

Lemma 8.6 (Frobenius pairings of a tight frame)**.** *Let $P = (N_0, d)$ be parameters, μ a natural number, p a prime number with $\chi_{K(P)}(p) \neq 1$ and $j\colon \mathbb{C} \to \mathbb{C}_p$ a ring homomorphism. Let J be a finite set, $w_i \in E(P,\mu)$ $(i \in J)$ and M a natural number such that (w_i) with multiplicities 1 is a tight frame of length M, and let $\beta \in \mathfrak{o}_p$. Then there are $z_{v,i} \in \mathfrak{o}_p$, for $v \in \mathrm{Pl}(P,\mu)$ and $i \in J$, with $z_{v,i} = \beta \cdot j(\overline{\iota_v(w_i)})$, such that for every commutative ring Q of characteristic p, every ring homomorphism $g\colon \mathfrak{o}_p \to Q$ that vanishes on the elements of absolute value at most $p^{(\chi_{K(P)}(p)-1)/2}$, every natural number e that is odd or for which $p = d$, and all $v, v' \in \mathrm{Pl}(P,\mu)$:*

$$\sum_{i \in J} g(z_{v,i})^{p^e}\, g(z_{v',i}) = \begin{cases} g(\beta)^{p^e} g(\beta) \cdot M & \text{if } [-p^e]_{P,\mu} \cdot v = v', \\ 0 & \text{otherwise.} \end{cases}$$

Proof. Let $N = N_1(P,\mu)$; it is prime to p (I4), so $\beta = N\beta'$ with $\beta' \in \mathfrak{o}_p$. The elements $x_i = N w_i$ are integers of $E(P,\mu)$ (I1). Then $z_{v,i} = \beta' j_v(x_i)$ lies in $\mathfrak{o}_p$. Let $\phi_v\colon x \mapsto g(j(\iota_v(x)))$ on the integers of $E(P,\mu)$. By (I6), $\phi_v(\mathrm{gal}(u)x) = \phi_v(\overline{x})^{p^e}$ for $u = [-p^e]_{P,\mu}$ and all x: the condition on $\sqrt{-d}$ holds because $-\chi_{K(P)}(p)^e = 1$ for e odd and $\chi_{K(P)}(p) = -1$, and because for $p = d$ the element $j(\sqrt{-d})$ has absolute value $p^{-1/2}$ and is killed by g. Hence

$$\sum_i g(z_{v,i})^{p^e} g(z_{v',i}) = g(\beta')^{p^e} g(\beta') \cdot g\Big(j\Big(\sum_i \iota_{u\cdot v}(x_i)\, \overline{\iota_{v'}(x_i)}\Big)\Big),$$

and the inner sum is $N^2 M$ if $u \cdot v = v'$ and 0 otherwise, by the frame identity. As $g(N)^{p^e} = g(N)$ in characteristic p (N is an integer) and $\beta = N\beta'$, the factor $g(\beta')^{p^e} g(\beta') \cdot g(N^2 M)$ is $g(\beta)^{p^e} g(\beta) \cdot M$, which is the claim. □

LEAN `Parameters.exists_frame_rows_frob`

Proof of Theorem D. Apply Proposition 8.4 to $C = \mathcal{E}(P)$; since $\chi_{K(P)}(p) \neq 1$ we have $p \geq 13$ (I4), so (II) holds. This gives ν, ϖ, ϖ_0, S, E and u_0, u_1, u_2, R, ψ. Let I, $r \leq 1$ and $\Theta \in \mathrm{ThProd}_{P,\mu}(1, r; I)$ be given, with frame $(w_i)_{i\in J}$ of length M, numbers n, b and translations $y_{(i,k)}$; so $p \nmid M$, $p \nmid n$, $|j(b)|_p = r$, $n\, y_{(i,k)} \in \Lambda_{\mathcal{E}(P)}$. Let N, κ and $V_{(i,k)}$ be as in (II) for this n. Lemma 8.6 with $\beta = Nj(b)$ gives $z_{v,i}$. Put

$$\ell_{(i,k)} = \sum_v z_{v,i}\, z_{(v,k)}, \qquad \Psi = \sum_{(i,k)} \psi(\ell_{(i,k)}), \qquad V = \prod_{(i,k)} V_{(i,k)}(\ell_{(i,k)}),$$

where $z_{(v,k)}$ are the variables. Substituting in the definition of the theta product, $\Theta(\varpi z) = \prod_{(i,k)} (\exp(\kappa\psi) V_{(i,k)})(\ell_{(i,k)}) = \exp(\kappa\Psi)\, V$, and $\Psi(0) = 0$.

(a) Let B, a family Z as in Definition 2.5 with couplings in the ideal (p, ϖ_0) for $e \in S_B$, and an exponent β_0 of degree at most B be given. Let Q be the quotient of $\mathfrak{o}_p[[T]]$ by the ideal of the series whose coefficients at the exponents $\leq \beta_0$ have absolute value at most $|\varpi_0|_p$; it has characteristic p. In Q let $t_{(i,k)}$ and $L_{(i,k)}$ be the classes of $S(\ell_{(i,k)}(Z))$ and of $\ell_{(i,k)}(Z) = \sum_v z_{v,i} Z_{(v,k)}$. Then $t - t^{p^\nu} = L$, and $t^{p^l} = 0$ for $p^l > B$. By Lemma 8.6 (for the map $\mathfrak{o}_p \to Q$, which kills the elements of absolute value $\leq |\varpi_0|_p$),

$$\sum_{(i,k)} L_{(i,k)}^{p^e} L_{(i,k)} = \beta^{p^e+1} M \sum_{(v,k)} Z_{(v,k)}^{p^e} Z_{(\mathrm{pr}_e(v),k)}$$

for e odd or $p = d$; this is 0 in Q for $e \in S_B$ by the hypothesis on Z, and for $e > \log_p B$ because then $L^{p^e} = 0$. Lemma 8.5(a), with the proposition $p = d$, gives $\sum t^{p+1} = \sum t^{p+p^\nu} = 0$. Moreover $u_0 \sum L^2 = 0$: either $u_0 = 0$, or $p = d$ and this is the coupling with $e = 0 \in S_B$. So the class of $\Psi(Z)$ vanishes: its coefficients at exponents $\leq \beta_0$ have absolute value at most $|\varpi_0|_p$. Then the coefficient at β_0 of $\exp(\kappa\Psi(Z)) = \sum_l \kappa^l \Psi(Z)^l / l!$ is integral, since $|\kappa\varpi_0|_p^l = p^{-l/(p-1)} \leq |l!|_p$; the same holds at every exponent $\leq \beta_0$, and $V(Z)$ is integral. So the coefficient of $\Theta(\varpi Z)$ at β_0 is integral.

(b) Now $\chi_{K(P)}(p) = -1$ and $r = 1$; so $\nu = 2$, $u_0 = 0$, $|u_1|_p = 1$, $|\kappa|_p = p^{1-1/(p-1)}$, and β is a unit. Reduce modulo $\mathfrak{m}_p$ and let $t_{(i,k)}$ be the reduction of $S(\ell_{(i,k)})$; then $t_{(i,k)} - t_{(i,k)}^{p^2} = \sum_v \overline{z}_{v,i} z_{(v,k)}$ with the residues $\overline{z}_{v,i}$, and for a variable $x = (x_1, x_2)$

$$\frac{\partial \overline{\Psi}}{\partial z_x} = \overline{u}_1 \sum_{i\in J} t_{(i,x_2)}^{p}\, \overline{z}_{x_1,i},$$

because $(p+1)t^p \partial t = t^p \partial t$, the derivative of t^{p^2} is 0, $p + p^2 \equiv 0$ and $\varpi_0 \equiv 0$. By Lemma 8.5(b) the coefficient at z^{β_0} is nonzero exactly for $\beta_0 = p^{2l+1} 1_{(y,x_2)}$ with $\sum_i \overline{z}_{y,i}^{\,p^{2l+1}} \overline{z}_{x_1,i} \neq 0$, and by Lemma 8.6, with β and M units, this means $[-p^{2l+1}]_{P,\mu} \cdot y = x_1$. □

9 Divisibility of Schur jets

Lemma 9.1 (frames that kill the couplings)**.** *Let p be a prime number, Φ and n finite sets, $\mathrm{pr}\colon \mathbb{N}\times\Phi\to\Phi$ a map, $S\subset\mathbb{N}$ a finite set, N a natural number, $\varkappa\colon \Phi\times\mathbb{N}\to\mathbb{N}$ a function, $\Xi\subset\Phi$ a finite set, $Y_{\tau,a,k}\in\mathfrak{o}_p$ for $\tau\in\Phi$, $a\in n$, $k\in\mathbb{N}$, and $\varpi_0\in\mathfrak{o}_p$. Then there are square matrices $M_{\tau,h}$ of size h over $\mathfrak{o}_p$, for $\tau\in\Phi$ and $h\in\mathbb{N}$, such that*

(i) $|\varpi_0|_p^{\sum_{e\in S}\sum_{\tau\in\Phi}\mathrm{cc}_p(\varkappa,N;\Xi;\tau,\mathrm{pr}_e(\tau);e)} \le \prod_{\tau\in\Phi}\prod_{h<N}|\det M_{\tau,h}|_p^{\varkappa(\tau,h)}$*;*

(ii) for every commutative ring R of characteristic p, every ring homomorphism $g\colon\mathfrak{o}_p\to R$ with $g(\varpi_0)=0$, every $e\in S$, $\tau\in\Phi$, heights h, h' and rows $i<h$, $i'<h'$: unless $h=1$ and ($\tau\in\Xi$, or $h'=1$ and $\mathrm{pr}_e(\tau)\in\Xi$),

$$g\Big(\sum_{a\in n}\Big(\sum_{k<h}(M_{\tau,h})_{i,k}Y_{\tau,a,k}\Big)^{p^e}\cdot\sum_{k<h'}(M_{\mathrm{pr}_e(\tau),h'})_{i',k}Y_{\mathrm{pr}_e(\tau),a,k}\Big)=0.$$

Proof. Fix p^e-th roots $\varpi_0^{1/p^e}\in\mathfrak{o}_p$. For a coupling (e,τ) with partner $\tau'=\mathrm{pr}_e(\tau)$ and a pair of heights (h,h') the pairing in (ii) can be made divisible by ϖ_0 from either end: by a condition on the rows of $M_{\tau,h}$ that costs ϖ_0^{1/p^e} (its p^e-th power appears), or by one on the rows of $M_{\tau',h'}$ that costs ϖ_0. Three devices are used. (1) Multiply all of $M_{\tau,h}$ by ϖ_0^{1/p^e}, or all of $M_{\tau',h'}$ by ϖ_0: this kills the couplings with all rows at the other end, and costs h/p^e, respectively h', in the valuation of the determinant, per column. (2) If $h'=1$, ask only that ϖ_0^{1/p^e} divide the pairings of the rows of $M_{\tau,h}Y_\tau$ with the single row of $Y_{\tau'}$: one linear condition on the rows, which by the input below costs $1/p^e$ per column. (3) If $h=1$, ask that ϖ_0 divide the pairings of the rows of $M_{\tau',h'}Y_{\tau'}$ with the p^e-th power of the single row of Y_τ: cost 1 per column. For $h,h'\neq1$ use (1) at the cheaper end, which costs $\min(B_\tau/p^e,B_{\tau'})$ in all; for $h\neq1$, $h'=1$ use (2), cost r_τ/p^e; for $h=1$ and $\tau\notin\Xi$ use (1) on the 1×1 matrix $M_{\tau,1}$ or (3) on all $M_{\tau',h'}$, whichever is cheaper, cost $\min(t_\tau/p^e,r_{\tau'}+t_{\tau'})$; the couplings exempted in (ii) are not treated. The total is the coupling count. All conditions on one matrix $M_{\tau,h}$ are imposed at once by the following input, applied to the diagonal matrix of the required roots of ϖ_0: *(unit 149) if A is a square matrix over a valuation ring and Λ a submodule containing the image of A, then for vectors $\Phi_1,\dots,\Phi_h$ there is a square matrix M of size h with $\det M$ dividing $\det A$ and all $\sum_k M_{i,k}\Phi_k$ in Λ.* In (ii) one raises the divisibility by ϖ_0^{1/p^e} to the power p^e, which in characteristic p is additive. The bookkeeping that decides which device serves which coupling is a predicate of the formal text; that its costs add up to the coupling count is checked there by a case analysis, which I read but did not replay (see §12). □

LEAN `exists_null_coupling_frames` · unit 149: `IndexDvd.of_det_dvd`

Proof of Theorem E. Step 1: from Schur entries to products of minors. For a matrix y_τ of size $n\times N$ (rows $a\in n$, columns $k<N$) the row i' of the Schur matrix satisfies $\sum_i S_\varkappa(z)_{i',i}\,b_i(y)=b'_{i'}(zy)$, where $b_i(y)$ are products of minors of y (times powers of determinants) and

$$b'_{i'}(zy)=\prod_\tau\prod_{h<N}\prod_{l<\varkappa(\tau,h)}\det\big((z_\tau y_\tau)_{i'_\tau(h,l,s),\,k}\big)_{s,k<h}$$

is the product of minors prescribed by i' (quoted: this is the identity that defines the Schur matrix, and its coefficients are integers). Two quoted facts finish the reduction. *(G)* For a polynomial f over $\mathbb{C}_p$ in finitely many variables there is a point

y_0 with coordinates in $\mathfrak{o}_p$ such that $|c|_p \le |f(y_0)|_p$ for every coefficient c of f. *(C)* If a polynomial f in the entries of y, over a commutative ring, is a combination $\sum_i x_i\, b_i(y)$ of the products $b_i(y)$, and every coefficient of f lies in an additive subgroup A of the ring, then every x_i lies in A. Regard $b'_{i'}(zy)$ as a polynomial in y whose coefficients are polynomials in z. Taking the jet of Θ along each coefficient gives a polynomial over $\mathbb{C}_p$ in y, whose value at a point y is $\mathrm{jet}_{b'_{i'}(zy)}(\Theta)$; apply (G) to it, which gives y_0. Then apply (C) to $f = b'_{i'}(zy)$, to $x_i = S_\varkappa(z)_{i',i}$ and to the set A of the polynomials Q in z with $|\,\mathrm{jet}_Q(\Theta)|_p \le |\,\mathrm{jet}_{b'_{i'}(zy_0)}(\Theta)|_p$, which is an additive group because the jet is additive in Q and the absolute value is ultrametric. Hence

$$|\,\mathrm{SJ}_\varkappa(\Theta)_{i',i}|_p \;\le\; |\,\mathrm{jet}_{b'_{i'}(zy_0)}(\Theta)|_p,$$

and it suffices to bound the jet of Θ along the polynomial $z \mapsto b'_{i'}(zy_0)$. From now on y is this point y_0.

Step 2: the null family. Let $M_{\tau,h}$ be the matrices of Lemma 9.1 for $Y = y$ and ϖ_0. Take new variables $X_{(h,k),(\tau,b)}$, for $k < h < N$, $\tau \in \Phi$, $b \in n'$, and the linear forms

$$Z_{(\tau,b,a)} = \sum_{k<h<N} p^{\,g(\tau,h,b)} \Big(\sum_{k'<h} (M_{\tau,h})_{k,k'}\, y_{\tau,a,k'} \Big) X_{(h,k),(\tau,b)}.$$

The coupling of exponent $e \in S$ of this family is, modulo p, a combination of the pairings of Lemma 9.1(ii) with coefficients $p^{\,g(\tau,h,b)p^e + g(\tau',h',b)}$, $\tau' = \mathrm{pr}_e(\tau)$. The pairings that are not exempted vanish modulo ϖ_0; for the exempted ones the hypothesis on the charges makes the coefficient divisible by p. So the family is null, and the hypothesis of the theorem says that the coefficients of degree at most B of $\Theta(\varpi Z)$ are integral.

Step 3: the jet. Multiplying the columns of a minor by $M_{\tau,h}$ and its row at b by $\varpi p^{g(\tau,h,b)}$ multiplies it by $\det M_{\tau,h} \prod_b \varpi p^{g(\tau,h,b)}$. So

$$\prod_{\tau,h} (\det M_{\tau,h})^{\varkappa(\tau,h)} \cdot \varpi^B p^m \cdot b'_{i'}(zy) = \mathsf{D}((\varpi Z)),$$
$$\mathsf{D}(X) = \prod_{\tau,h,l} \det\big(X_{(h,k),(\tau,i'_\tau(h,l,s))}\big)_{s,k<h},$$

where the right side is read through the transpose of the linear substitution; by the chain rule for jets (quoted), the jet of Θ along the left side is the jet of $\Theta(\varpi Z)$ along D. Now D is a sum of monomials $\pm X^\beta$ of degree B, and the jet along X^β is $\beta!$ times a coefficient of degree B, which is integral. The exponent β has at most $|\Phi|N^3$ entries, each at most B, and $v_p(l!) \ge l/(p-1) - (\lfloor \log_p B \rfloor + 1)$ for $l \le B$ by Legendre's formula; so $|\beta!|_p \le p^{\,-B/(p-1) + |\Phi|N^3(\lfloor \log_p B \rfloor + 1)}$. By Lemma 9.1(i), $|\varpi|_p = p^{-\rho}$ and $|\varpi_0|_p = p^\omega$, the factor on the left has absolute value at least $p^{\,\omega \sum \mathrm{cc} - \rho B - m}$. Dividing gives the theorem. □

10 Sharpness

Proposition 10.1 (a limit to the divisibility of Taylor coefficients)**.** *Let d be a prime number $\equiv 7 \bmod 8$, C a CM datum for d, (p,j) a p-adic place and n a natural number. Then there is $F \in \mathfrak{o}_p[[\varphi_C]]$ with*

$$\left(p^{\,\varrho_d(p)-1/(p-1)}\right)^n \;\le\; |n!\cdot F_n|_p.$$

Proof. Let $c_0 = p^{\varrho_d(p)-1/(p-1)}$ and, for $k \in \mathbb{N}$, let $c(k)$ be the largest value of $|k!F_k|_p/c_0^k$ for $F \in \mathfrak{o}_p[[\varphi_C]]$; by (Q5) it is attained at a power of $\hat\varphi = \mathrm{Tay}_j(\varphi_C)$. *$c$ is submultiplicative.* By (Q5), $\hat\varphi(X+Y)^l$ is an integral series in $\hat\varphi(X)$ and $\hat\varphi(Y)$; its coefficient at X^nY^k is $\binom{n+k}{n}(\hat\varphi^l)_{n+k}$, and it is bounded by the largest product of an n-th coefficient of a power of $\hat\varphi$ with a k-th one. Multiplying by $n!\,k!$ gives $c(n+k) \le c(n)c(k)$. Suppose the proposition fails for n: $c(n) < 1$. Then $c(k) \to 0$, so there is l_0 with $c(k) < |\varpi|_p$ for $k \ge l_0$, where ϖ, ϖ_0, S, T, ν are those of Proposition 8.4(I). From $T(\varpi X) = \varpi S$, $|T_k|_p \le c(k)c_0^k/|k!|_p$, $|k!|_p \ge p^{-k/(p-1)}$ and $|\varpi|_p = p^{-\varrho_d(p)}$ we get $|S_k|_p = |\varpi|_p^{k-1}|T_k|_p \le c(k)/|\varpi|_p < 1$ for $k \ge l_0$. So the reduction $\overline{S}$ of S modulo $\mathfrak{m}_p$ is a polynomial. But $\overline{S} - \overline{S}^{p^\nu} = X$, because $|\varpi_0|_p < 1$, and no polynomial satisfies this: the degree of the left side is $p^\nu \deg \overline{S} \ne 1$. □

LEAN `CMLattice.katz_divisibility_limit`

Lemma 10.2 (the live sum)**.** *(a) Let d and p be prime numbers with $\chi_d(p) \ne 1$ and c a real number. Then*

$$\sum_{\substack{e\ge 1\\ e\ \text{odd or}\ p=d}} \frac{c}{p^e} = \frac{2}{1-\chi_d(p)}\cdot c\cdot\Big(\frac{1}{p-1} - \varrho_d(p)\Big),$$

the series being convergent.

(b) Let D be admissible data for parameters $P = (N_0, d)$, p a prime number with $\chi_{K(P)}(p) \ne 1$, y a real number and $\tau \in \mathrm{Pl}(D)$. Then the family of the terms $\big(y/p^e - w_D([-p^e]_D\cdot\tau)\big)_+$, over the $e \ge 1$ that are odd or for which $p = d$ (and 0 for the other e), is summable; so the sum in $\mathrm{ask}_{D,p}(y,\tau)$ is an ordinary sum.

(c) Let D be admissible data for parameters $P = (N_0, d)$, p and e natural numbers and $\tau \in \mathrm{Pl}(D)$. If $[-p^e]_D\cdot\tau$ and τ have the same class modulo N_0, then $p \ne d$.

(d) Let D be admissible data, $\tau \in \mathrm{Pl}(D)$, and h, a natural numbers. Then, with $k = k(D)$,

$$\begin{cases} a & h = 1 \\ \varkappa_D(\tau,h) & h \ne 1 \end{cases} \;\le\; \begin{cases} a & h = 1 \\ 0 & h \ne 1 \end{cases} + \begin{cases} \mathrm{wt}_D(1,\tau) & h = k \\ 0 & h \ne k \end{cases} + \mathrm{gap}(D).$$

Proof. (a) In both cases, $\chi_d(p) = -1$ and $\chi_d(p) = 0$ (then $p = d$), the term at $e \ge 0$ is $\frac{c}{1-\chi_d(p)}(p^{-e} - (\chi_d(p)/p)^e)$; sum the two geometric series. (b) The terms are bounded by $|y|/p^e$, since the nominal weight is non-negative; use (a). (c) If $p = d$, then $-d^e$ is prime to $N_1(D)$, the class of $[-d^e]_D\cdot\tau$ is $-d^e$ times that of τ, and equal classes would give $d^e \equiv -1 \bmod N_0$, against (I4). (d) Unfold Definition 2.9. □

Proposition 10.3 (a Frobenius packing for the nominal weights)**.** *Let D be admissible data for parameters $P = (N_0, d)$, with component x, and let $n\colon \mathrm{Pl}(D) \to \mathbb{N}$ satisfy $w_D(\tau) \le n_\tau \le w_D(\tau) + x^{42}$ for every τ. Let p be a prime number with $\chi_{K(P)}(p) \ne 1$. Then there are functions $i, y\colon \mathrm{Pl}(D) \to \mathbb{N}$ such that (i, y) is a Frobenius packing of n at p and, with*

$$L = \mathrm{forced}(D, p) + \sum_{\tau \in \mathrm{Pl}(D)} v_p(\mathrm{dl}_D(n_\tau)),$$

either $\chi_{K(P)}(p) = -1$, $i_\tau = 1$ for all τ and $\sum_\tau (v_p(n_\tau!) - y_\tau) \le L$, or

$$\sum_{\tau \in \mathrm{Pl}(D)} \Big((\tfrac{1}{p-1} - \varrho_d(p)) n_\tau + 4\, b_2(D) - y_\tau \Big) \;\le\; L.$$

Proof. Write $k = k(D)$, $c = \lceil 60b/k \rceil$, $w = w_D(\,\cdot\,)$, $[u] = [u]_D$, and $A(l) = (l - c + 1) \cdots (l - c + c)$ with truncated $l - c$, so that $\mathrm{dl}_D(l) = A(l)^2$. Two facts: $l!$ divides $(l - c)!\, A(l)$; and $c!$ divides $A(l)$, a product of c consecutive integers.

Case $k < p$. Then $p \ne d$ by (S1), so $\chi_{K(P)}(p) = -1$. Take $i_\tau = 1$ and $y_\tau = \min(n_{[-p]\tau}, \lfloor (n_\tau - c)/p \rfloor)$. By (S1), $\lfloor (n_\tau - c)/p \rfloor \le 2b/k \le c$. Packing: (1) holds, (2) is empty, and for (3) the only τ with $[-p]\tau = \tau'$ has $y_\tau \le \min(n_{\tau'}, c)$, while $p\, y_{\tau'} \le n_{\tau'} - c$ (truncated); the sum is at most $n_{\tau'}$. For the bound, Legendre's formula and the two facts give

$$\begin{aligned} v_p(n_\tau!) &\le v_p((n_\tau - c)!) + v_p(A(n_\tau)) \\ &= \lfloor (n_\tau - c)/p \rfloor + v_p(\lfloor (n_\tau - c)/p \rfloor!) + v_p(A(n_\tau)) \\ &\le \lfloor (n_\tau - c)/p \rfloor + v_p(\mathrm{dl}_D(n_\tau)), \end{aligned}$$

and $\lfloor (n_\tau - c)/p \rfloor - y_\tau \le ((n_\tau - c)/p - n_{[-p]\tau})_+ \le (w(\tau)/p - w([-p]\tau))_+$, because $n_\tau - c \le w(\tau)$ by (S1). The last number is the term $e = 1$ of $\mathrm{ask}_{D,p}(w(\tau), \tau)$ (all terms are non-negative, Lemma 10.2(b)). Summing over τ gives the first alternative.

Case $p \le k$. For odd e, $[-p^e] = [-p]^e$. *Claim: for $0 < i < l \le 324\mu(D)$ the places τ, $[-p]^i\tau$, $[-p]^l\tau$ are not all thick.* Otherwise (S3) gives $(-p)^i \equiv 1 \bmod 2^{\mu(D)+1}$, and (S4) gives $2^{\mu(D)} \le (p+1)i$, which the sizes of the data exclude for $p \le k$. Say that e *pairs* τ if $e < \mu(D)$, e is odd, $p \ne d$, and τ and $[-p]^e\tau$ are thick. By the claim at

most one e pairs τ. If e pairs τ put $i_\tau = e$, $y_\tau = \lfloor n_\tau/p^e \rfloor$; otherwise $y_\tau = 0$. Packing: (1) holds since $p \neq d$ and $\chi_{K(P)}(p) \neq 1$. (2): if $[-p]^e\tau' = [-p]^{i_\tau}\tau$ with $e < i_\tau$ odd, then $\tau' = [-p]^{i_\tau - e}\tau$, and τ, τ', $[-p]^{i_\tau}\tau$ would be thick, against the claim. (3): if no τ with $y_\tau \neq 0$ has $[-p]^{i_\tau}\tau = \tau'$, the sum is $p^{i_{\tau'}} y_{\tau'} \leq n_{\tau'}$. Otherwise there is exactly one such τ, and $y_{\tau'} = 0$, both by the claim; and $y_\tau \leq n_\tau/p \leq n_{\tau'}$ since both places are thick and $n_\tau \leq a(D)/x + x^{42} \leq 2\, n_{\tau'}$ by (S1).

The bound. Fix τ. We compare, term by term in $e \geq 1$ (e odd or $p = d$),

$$\frac{n_\tau}{p^e} \;\leq\; \Big(\frac{w(\tau)}{p^e} - w([-p^e]\tau)\Big)_+ + [e = i_\tau]\, y_\tau + \frac{c}{p \cdot 2 \cdot 2^e}. \tag{4}$$

If $e \geq \mu(D)$, the left side is at most $2b/p^e$ and the second half of (S2) applies, as $p \geq 13$ by (I4). Let $e < \mu(D)$. If e pairs τ, then $n_\tau/p^e \leq y_\tau + 1$ and the last term is at least 1 by (S2). If not, then τ and $[-p^e]\tau$ are not both thick: for $p = d$ this is Lemma 10.2(c) with (S3), and for $p \neq d$ it is the definition. If τ is not thick, $n_\tau \leq 2a(D)/x_1$ by (S1), and (S2) applies. If τ is thick and $[-p^e]\tau$ is not, then $w([-p^e]\tau) = a(D)/x_1$ and $n_\tau/p^e \leq (w(\tau)/p^e - a(D)/x_1)_+ + a(D)/x_1 + x^{42}$, and (S1), (S2) apply. Summing (4) over e with Lemma 10.2(a), and multiplying by $(1 - \chi_{K(P)}(p))/2 \leq 1$:

$$\big(\tfrac{1}{p-1} - \varrho_d(p)\big) n_\tau - y_\tau \;\leq\; \mathrm{ask}_{D,p}(w(\tau), \tau) + \frac{c}{p}.$$

Finally $v_p(\mathrm{dl}_D(n_\tau)) \geq 2v_p(c!) \geq 2(c/p - 1) \geq c/p + 4b_2(D)$, the last step by (S2) at $e = 0$. Summing over τ gives the second alternative. □

LEAN `Data.exists_isFrobPacking`

Proof of Theorem F. We write z_τ for the variable $z_{(\tau,*)}$. By (I4), $p \geq 13$. Let ϖ be as in Theorem D and $F = \Theta(\varpi z)$. If $y = 0$ the assertion holds with $\beta = \gamma = 0$, since $|(\Theta^{-1})_0|_p |\Theta_0|_p = 1$; so let $y \neq 0$. For τ with $y_\tau \neq 0$ let $\tau^* = [-p^{i_\tau}]_{P,\mu} \cdot \tau$; by the packing i_τ is odd and $\chi_{K(P)}(p) = -1$, so Theorem D(b) gives $F = \exp(\kappa\Psi)V$ with $|\kappa|_p = p^{1-1/(p-1)} > 1$. As $\Theta(0) = 1$ and $\Psi(0) = 0$, V is a unit of $\mathfrak{o}_p[[z]]$.

Step 1: one derivative. Let Q be an integral series and τ a place with $y_\tau \neq 0$, and put $R = \partial_{\tau^*}\Psi \cdot Q + \kappa^{-1}(\partial_{\tau^*}Q + Q\,V^{-1}\partial_{\tau^*}V)$, an integral series. Then $\partial_{\tau^*}(QF) = \kappa\, RF$, hence for every polynomial G: $|\,\mathrm{jet}_{G\cdot z_{\tau^*}}(QF)|_p = |\kappa|_p \cdot |\,\mathrm{jet}_G(RF)|_p$. Modulo $\mathfrak{m}_p$, $\overline{R} = \partial_{\tau^*}\overline{\Psi} \cdot \overline{Q}$. Give the variable z_σ the weight 1 if $y_\sigma \neq 0$ and the weight $p^{\max i}$ otherwise. By Theorem D(b) the monomials of $\partial_{\tau^*}\overline{\Psi}$ are the $z_\sigma^{p^e}$ with e odd and $[-p^e]_{P,\mu} \cdot \sigma = \tau^*$; by condition (2) of the packing the one of least weight is $z_\tau^{p^{i_\tau}}$, and it is the only one of that weight.

Step 2: all derivatives. Starting from $Q = 1$ and applying Step 1 y_τ times for every τ, we get an integral Q whose reduction has the lowest term $u\, z^\lambda$, $u \neq 0$, $\lambda = \sum_\tau y_\tau p^{i_\tau} 1_\tau$ (lowest terms multiply), and with

$$|\kappa|_p^{|\gamma|}\, |\,\mathrm{jet}_G(QF)|_p = |\,\mathrm{jet}_{G\cdot z^\gamma}(F)|_p \qquad \text{for all } G, \qquad \gamma = \sum_\tau y_\tau 1_{\tau^*}.$$

Step 3: a large coefficient. The coefficient Q_λ is a unit. Since $Q = F^{-1} \cdot (QF)$, there are exponents $\gamma_1 + \beta_1 = \lambda$ with $1 \leq |(F^{-1})_{\gamma_1}|_p |(QF)_{\beta_1}|_p$. Step 2 with $G = z^{\beta_1}$ gives $|\kappa|_p^{|\gamma|} |\beta_1!|_p |(QF)_{\beta_1}|_p = |(\beta_1 + \gamma)!|_p |F_{\beta_1+\gamma}|_p$. With $F_\alpha = \varpi^{|\alpha|}\Theta_\alpha$, $(F^{-1})_\alpha =$

$\varpi^{|\alpha|}(\Theta^{-1})_\alpha$, $|\varpi|_p = p^{-\varrho_d(p)}$ and $|\beta_1!|_p/|(\beta_1+\gamma)!|_p \geq |\gamma!|_p^{-1}$, this yields, for $\beta = \gamma_1+\beta_1+\gamma$,

$$|(\Theta^{-1})_{\gamma_1}|_p \cdot |\Theta_{\beta_1+\gamma}|_p \;\geq\; p^{(1-\frac{1}{p-1})|\gamma|+\varrho_d(p)|\beta|+\sum_\tau v_p(\gamma_\tau!)}.$$

Split γ_1 into five exponents by the hypothesis on Θ^{-1} and keep $\beta_1+\gamma$ as the sixth, by the hypothesis on Θ. Finally $|\gamma| = \sum y_\tau$, $|\beta| = |\lambda|+|\gamma| = \sum y_\tau(p^{i_\tau}+1)$, and $\gamma \leq \beta \leq n$ by condition (3) of the packing: the entry of β at τ' is $p^{i_{\tau'}}y_{\tau'} + \sum_{\tau^*=\tau'} y_\tau$. □

LEAN `exists_hasLargeSplit_of_pairs`

11 Where the results are used

By name, as the dossier of the unit lists the uses (a search over the sources, not a kernel export). The unit on the columns (unit 145) uses all the definitions of §2 on asks, gains, losses, served primes, collisions, coupling counts and column counts, Theorems C, D and E, Proposition 7.4 and Theorem A, to prove that the chain of lifts is divisible by $p^{\mathrm{gain}(D,p)}$ up to the loss. The unit on the rows uses Proposition 10.1, Proposition 10.3 and Theorem F for the lower bound of a jet (the glued form), and Theorem B, with Lemma 6.2 and Lemma 6.3, where conjugates of lifts are bounded. The unit on the data uses Proposition 6.1: its constant $C(P)$ contains the chosen number $C_{\mathrm{gen}}(P)$.

12 Notes on the formal text

1. *Arguments that the text of the census lists and Lean does not take.* The dossier of the unit was made without running Lean, and its lists of arguments are those of a reading of the text. For three definitions the reading lists a section variable that only occurs as a bound index: τ in the gain and in the collision sum, and the height h in the coupling count. The source applies them to two, three and seven arguments (`D.gain p`, `D.collisionSum p ev`, `couplingCount p κ N ev σ (pr e σ) e`), and this note writes them so, $\mathrm{gain}(D,p)$, $\mathrm{coll}(D,p,\Xi)$, $\mathrm{cc}_p(\varkappa,n';\Xi;\tau,\tau';e)$, through macros of its own; the build accounts for the extra entry by the bound letter in Definition 2.6, 2.7, 2.8. The same happens for arguments of theorems and of one more definition: the index set J of a theta product, bound by "there are"; a ring Q bound inside Lemma 8.6; the letters c and K in Theorem B; a field E in Lemma 7.1(d) and Proposition 5.2; the prime and its place in Lemma 4.2; a second finiteness of n in the parts of Lemma 6.2; and the instance "V is standard" in Lemma 5.1(c), whose space is only assumed to have signs 1. All of this should be confirmed with `#check` once a build is at hand.

2. *Arguments that Lean takes and the reading cannot see.* Four places use the notation of the formal text for the p-adic place: Lemma 3.2(b)–(d), Theorem A, Definition 2.3 and Proposition 7.4. This notation makes the prime p and the homomorphism j arguments (an implicit one and two instance arguments). The statements above name them. Likewise the module $\mathrm{Std}_\delta(V)$ depends on j, and so does the set $\mathrm{ThProd}_{P,\mu}(\delta,r;c)$; the notation does not show it, because j is an instance argument.

3. *Three statements that the census cuts short.* The statements of Proposition 7.4(b), of Proposition 10.3 and of Theorem E contain a `let`, which the census takes

for the end of the statement. I read these statements in the source in full; the quotations of Appendix A avoid them. For the same reason three intermediate facts of the dossier are cut short (in the proofs of Lemma 9.1, of Lemma 8.3 and of Theorem A); its claims state them in full, and I read the lines.

4. *An error in the words of the first dossier, since corrected.* In the structured proof of Proposition 8.4 the dossier said that the pairs $(\zeta^i, 1)$ lie in the closure $\mathcal{N}_d$. The lemma of the library that the formal proof applies gives $(\zeta^i, \zeta^{i(p+1)})$, as in (Q6) above, and this is what makes the proof work: the exponential factor of the normal form is the part of $\log \theta_C$ in the degrees $\equiv p+1$ modulo $q-1$ precisely because of the exponent $p+1$. With the pairs $(\zeta^i, 1)$ one would obtain the part in the degrees $\equiv 0$. The quotations of the dossier were exact; only its words were affected (steps 7 and 35.6), and its record of corrections now has the pairs $(\zeta^i, \zeta^{i(p+1)})$ and the weight $\zeta^{-i(p+1)}$, as here.

5. *Proofs that are shorter here, or differently arranged.* The frame identity of Step 2 of Theorem A is established in the formal text by a Gröbner basis computation; the computation above replaces it. The estimate at the end of Lemma 8.3 is closed in the formal text by automation from the bounds of Lemma 8.1; the division into the cases $I \le 4$ and $I \ge 5$ is mine. In Proposition 10.1 the formal text ends as here: the reduction $\overline{S}$, a polynomial, would satisfy $\overline{S} - \overline{S}^{p^\nu} = X$, against the degrees. In Proposition 6.1 the formal text does not use that a_1 determines the lattice: it defines the conjugate datum by choice from the invariant, as Background 3 does. In Step 4 of Proposition 8.4 the arithmetic in the three cases is done by automation in the formal text.

6. *What I could not settle without Lean.* (a) In Lemma 9.1 the formal proof encodes the choice of the device for each coupling in one predicate and verifies the equality of exponents by a case analysis with automation; I read the construction and checked the three costs against the coupling count, but did not replay the case analysis. (b) In Theorem B(iv) the packing estimate and the final inequality between exponentials are a chain of automated steps; the proof above gives their structure and not their constants. (c) In Proposition 8.4 the final identity of Step 6 is a single simplification in the formal text; the computation above is the mathematics that it must carry out, with the pairs of note 4. (d) The inputs (S1)–(S2) are not separate declarations: the formal proof of Proposition 10.3 obtains each of them in place from the lemma of unit 152 that compares logarithmic sizes. I state them as I read them at the places of use; the second half of (S2) is my summary of a short chain there, which uses $4 \le p$ (available because $p \ge 13$) and is false for $p = 2$.

7. *Choices.* $\mathcal{E}(P)$, $\Omega_0(P)$, u_P, $\mathrm{vsc}(P, \mu)$ and $C_{\mathrm{gen}}(P)$ are obtained by choice from existence statements, the last two from Proposition 6.1 itself; so the definition of the scaled vacuum depends on the proof of that proposition having been given, not on its witnesses. The file of unit 152 that defines $C(P)$ imports this unit for the same reason.

8. *Conventions of the formal text that the statements inherit.* Sums over $e \in \mathbb{N}$ in Definitions 2.6 and 2.7 are unconditional sums with value 0 when the family is not summable; Lemma 10.2(b) shows that this does not occur in the ask for primes p with $\chi_{K(P)}(p) \neq 1$, and for $\chi_{K(P)}(p) = 1$ the factor in front is 0. The definitions

take a natural number p, not a prime. In Lemma 8.1 the last hypothesis has a default proof (the formal text supplies it by arithmetic automation when the numbers are explicit), and in Lemma 6.3 the adele η has a default value. In Lemma 10.2(d) the number a is arbitrary. The hypothesis $\nu \neq 0$ of Lemma 8.1 follows from $p^{\nu} = Q + 1$ only if $Q \neq 0$.

9. *The catalogue.* The relations stated for (Q2), (Q4) and (Q8) are those of the catalogue of the handout: the main theorem of complex multiplication in a soft form, the integrality of a_1 as a weaker form of good reduction everywhere, and the height of the formal group as one direction and an upper bound. For (Q3), (Q5), (Q6), (Q7), (Q9) and (Q10) the catalogue has no confirmed place; the files of the library name Bannai–Kobayashi (2010), Bannai–Kobayashi–Yasuda (2017), Katz (1981), Finis (2006), Mumford (1966), Conway–Sloane (1989) and Shimura (1976) as related work, and I did not compare the statements with these sources.

How this note was written. From the dossier of the unit: the texts of its 89 members and its 36 structured proofs, which I read in full in a condensed form (every claim, without the quoted lines). The program check of the dossier covered 407 leaf steps of 36 proofs and found every statement at its lines. I read all twelve Lean files of the unit, statements and proofs, and compared every statement of this note with its Lean text, argument by argument, with the list of arguments of the census beside it; for the statements named in notes 1 to 3 the source decided. In other units and in the library I read the definitions that the statements use (the structure of the data and its functions, tight frames, vacuum expansions, the jet series, Schur jets, gauges, kernels and the theta kernel, the CM datum with its functions, the ring $\mathfrak{o}_p[[\varphi_C]]$, carried series, admissible combinations) and the statements of the quoted results (Q2), (Q3), (Q6), (Q7), (Q8), of the input of unit 149 and of (I6); the other inputs are stated as the dossier reads them. I did not read proofs of the library. No Lean was run.

Appendix A. Concordance with the Lean artifact

```

In these texts `s` is the exponent μ, `Φ τ` the embedding ι_τ, `ιₚ` the homomorphism j, `valRingCp p` the ring $\mathfrak{o}_p$, `chiK P.d p` the value $\chi_{K(P)}(p)$, `nonsplitWeight P.d p` the number $\varrho_d(p)$, `P.placeOfInt s (-p ^ j) * v` the place $[-p^e]_{P,\mu}\cdot v$, `κ` a family of column counts $\varkappa$, `ev` the set Ξ, `taylorVia ιₚ` the series $\mathrm{Tay}_j(\,\cdot\,)$, `P.cmCurve.twistedTranslate 1 y` the translation $U_y^{\mathcal{E}(P),1}$, `expSubst` the exponential of a series without constant term and `residue` the reduction modulo $\mathfrak{m}_p$. Letters of the formal text were changed where the write-up reserves them: the exponent `s`, the Frobenius exponents `j` (here e), the degree `e` of the residue field (here ν), the element `θ` of the null cone (here ϖ_0) and the column counts `κ`.

Notation

$P = (N_0, d)$, μ parameters; the exponent

$K(P)$, $\mathcal{O}_{K(P)}$, $\chi_{K(P)}$, χ_d $\mathbb{Q}(\sqrt{-d})$, its integers, its quadratic character; the Legendre symbol modulo d

$E(P,\mu)$, $N_1(P,\mu)$, $\varsigma(P,\mu)$ the CM field, the order of its root of unity, that root

$\mathrm{Pl}(P,\mu)$, ι_τ, $[\nu]_{P,\mu}$ the group of infinite places; the embedding at τ; the place of an integer ν

$\tau, \tau', v, v', u, \sigma$ infinite places; σ also an automorphism of $\mathbb{C}$, u also a unit or a variable

$c_0(P,\mu)$, $\partial(P,\mu)$, $\alpha(P,\mu)$, $\mathrm{rd}_{E(P,\mu)}$ $(1+\sqrt{-d})/2$; the generator of the relative different; the idele; the root discriminant

$\Omega(P,\mu)$, $\mathrm{cs}(d)$ the period $e^{\mathrm{cs}(d)}2\pi/\mathrm{rd}_{E(P,\mu)}$; the Chowla–Selberg constant

$\mathfrak{a}(P,\mu)$ the lattice $E \cap \alpha\widehat{\mathcal{O}}$

$\mathbb{A}$, $\mathbb{A}_\mathrm{f}$, $\widehat{\mathcal{O}}$ adeles, finite adeles, integral finite adeles

$\mathrm{perm}_\mu(\sigma)$, $\Theta^{[\sigma]}$, π the permutation of places of σ; the renaming of the variables of a series by it; the circle constant

ϖ_0 the element of $\mathfrak{o}_p$ of the null cone, with $|\varpi_0|_p = p^{(\chi_{K(P)}(p)-1)/2}$ in Theorem D

(p,j), $\mathbb{C}_p$, $|\cdot|_p$, $\mathfrak{o}_p$, $\mathfrak{m}_p$, O_j a p-adic place and its objects

ψ, $\mathfrak{p}_\psi$, $\hat{\psi}$, j_τ, $\hat{\jmath}_\tau$ an embedding into $\mathbb{C}_p$, its prime, its extension to $\mathbb{A}_\mathrm{f}$; $j \circ \iota_\tau \circ$ conjugation

v_p, $\lfloor\rfloor$, $\lceil\rceil$, $()_+$ p-adic valuation, floor, ceiling, positive part

C, Λ_C, $\mathrm{area}(C)$, t, a_1 a CM datum, its lattice, area, point of order two, invariant

C_α, σC, A_0 the chosen CM datum with invariant α; the conjugate datum $C_{\sigma(a_1)}$; the conjugates of a_1 that are invariants

$\wp$, σ_C, θ_C, ξ_C, φ_C, $\mathrm{mon}_C(x)$ Weierstrass functions; theta; $\wp(z+t)-\wp(t)$; the parameter; monomial sections

$U_y^{C,m}$, H_C twisted translation; the hermitian form of C

$\mathrm{Tay}(F)$, $\mathrm{Tay}_j(F)$, $\hat{\varphi}$ Taylor series; the same read through j; $\mathrm{Tay}_j(\varphi_C)$

$\mathfrak{o}_p[[\varphi_C]]$, $\mathcal{N}_d$, $[F]_{r \bmod M}$ integral series in the parameter; the closure of norm pairs; part in a residue class of degrees

$s_0(P,\mu)$, $s_1(P,\mu)$, $\mathrm{per}(P,\mu)$, $\mathrm{asc}(P)$ root of the vacuum; period factor; scale of jets; $\sqrt{2\pi/\sqrt{d}}$

$\mathcal{E}(P)$, $\Omega_0(P)$, u_P the chosen CM datum, its period, its Chowla–Selberg number

χ_fin, υ, ψ_0 characters of the Weil data; the additive character of $\mathbb{A}_\mathrm{f}$

V, n, ε, I_n, $\mathrm{Hom}(I_n, I_{n'})$ a hermitian space, its index set, its signs; standard spaces

$\mathcal{S}(V)$, $\mathcal{W}_\mathrm{f}(V)$, vac_V, Th_V, ω_V, $\langle f, f'\rangle_V$ the Weil space, its finite part, vacuum, theta functional, representation, pairing

$\mathfrak{h}_V(y)$, $\mathfrak{h}^\mathrm{f}_V(x)$, $x^\flat$ Heisenberg operators; the adelic vector of a finite vector

$\mathrm{U}_n(\mathbb{A}_\mathrm{f})$, $\Delta_\mathrm{f}(g)$, 1_n the finite adelic unitary group, its multiplier, the unit matrix

$T_a^V f$, Θ_f, $\mathrm{jet}_Q(F)$ jet series; theta function of f; jet along Q

$\mathrm{name}_{V,R}(\Psi)$, $P^\mathfrak{m}$, $\mathfrak{m}$ named operators; the mean at a modulus; a modulus

$\mathrm{vsc}(P,\mu)$, θ°_V, $\mathrm{Lat}(\delta; S)$, $\mathrm{Std}_\delta(V)$ scale of the vacuum; scaled vacuum; a group of vectors; standard data

$C_\mathrm{gen}(P)$, $C(P)$ the chosen constant of Proposition 6.1; the constant of unit 152

$\varkappa$, $\mathrm{box}(\varkappa, N)$, $S_\varkappa$, $\mathrm{SJ}_\varkappa(F)$ column counts, boxes, Schur matrix, Schur jets

i, i', $i_\tau(h,l,b)$ Weyl indices and their entries; i also an index or the exponents of a packing

$\mathrm{gauge}_j^{\varkappa,e}(g;\xi)$, k, ω_k, jm_k, $\mathcal{D}$ gauge; a kernel, its representation, its matrices, its data

$\mathrm{k}_\varkappa(c; a, b; K)$, $\omega_{a,b}$, e_a, e_b theta kernel; Weil representation of the pair; weights of the characters a, b

$\mathrm{Raise}_k(d_1, d_2; c)$ data that raise gauges by at most c

$\mathrm{ThProd}_{P,\mu}(\delta, r; c)$ theta products

pr_e, S, S_B, Ξ the partner map; sets of Frobenius exponents; a set of exempted places

ϖ, κ, κ_0, Ψ, ψ, ν, q the scale at p; scalars of the exponential; its exponents; the degree and the norm of the prime above p

$\varrho_d(p)$ $1/(p^2-1)$, $1/(2(p-1))$ or $1/(p-1)$

D; x, x_1, b, m, r; $\mu(D)$ admissible data; its components (in Definitions 2.6–2.10 and §10); its exponent

$\mathrm{Pl}(D)$, $N_1(D)$, $f(D)$, $k(D)$, $t(D)$, $a(D)$, $[\nu]_D$ objects of the data (unit 152)

$\mathrm{tops}(D)$, $w_D(\tau)$, $\mathrm{wt}_D(l,\tau)$, $n_l(D)$, $\mathrm{gap}(D)$, $b_2(D)$ tops; nominal weight; weights; ranks; gap; a rounded weight

$\mathrm{ask}_{D,p}(y,\tau)$, $\mathrm{forced}(D,p)$, $\mathrm{gain}(D,p)$, $\mathrm{loss}(D,p)$ ask, forced part, gain, loss

$\mathfrak{r}(D,p)$, $\Delta(D,p)$, $\mathrm{jc}(D,p)$, $o_0(D,p)$, $\mathrm{coll}(D,p,\Xi)$ the numbers of Definition 2.7

$\mathrm{cc}_p(\varkappa, n'; \Xi; \tau, \tau'; e)$, t_σ, r_σ, B_σ coupling count and its parts

$\varkappa_D(\tau,h)$, $\mathrm{last}_D(l,\tau)$, $\mathrm{kept}_D(h)$, $\varkappa^Y_D(\tau,h)$ column counts of the data

$\mathrm{dl}_D(n)$, $A(l)$, L depth loss; an ascending factorial; a bound (also a linear form, a semilinear map, log of theta)

N, b, D a weight on exponents; a proposition; a product of determinants

$\alpha, \beta, \gamma, \lambda$, 1_y, z^β exponents (multi-indices), the exponent of one variable, monomials; α also the idele, β, γ, λ also numbers where said

z, z_x, X, Y, T, Z, W variables and families of series; z also an adele or an integer, T, Z, W series in Proposition 8.4

M, N, R, B, I, J, Q, A, H lengths, levels, sets, rings, bounds: local to each statement

$a, b, c, e, f, g, h, k, l, m, n, o, s, w, y$ numbers, indices, elements and functions local to each statement

E, F, G, S, U, O series, functions and sets local to each statement; E also a field

δ, η, ζ, θ, ρ, ω, ϕ, ξ, ℓ, ι, ς, ϵ an integer of $K(P)$; an adele; a root of unity; in θ_C; real exponents; a ring map; a vector; linear forms and primes; in ι_τ; the root of unity of E; coefficients

Φ, Θ, Ω, Λ, Δ, Π, ∂ a set of places or a datum; a series; periods; a lattice; a multiplier; a product; derivatives and the different

Columns on a definite unitary group: divisibility and size of the chain of theta lifts

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. A *column* is an algebraic modular form on a definite unitary group of rank $k(D)$ over the CM field $E(D)$, of a fixed weight and of a level that is principal at the chosen primes and of mirabolic type at the primes dividing an element $\pi_N(D)$ of norm the level prime $N(D)$. A chain of m theta lifts between definite groups, followed by a restriction, sends columns to forms on a group of larger rank; by the seesaw identity of another unit this map computes the chain of lifts of Poincaré series. This unit proves the three facts about columns that Theorem A of the handout needs. First, the columns that are *ramified* at the primes dividing $\pi_N(D)$ are spanned by forms that are integral at all primes and whose conjugates are all small. Second, at every prime p the chain is divisible by $p^{\mathrm{gain}(D,p)}$, up to an allowed error, on a submodule of the integral columns of small index; at an inert prime that pairs two of the top places, the divisibility is regained on the image of scaled Hecke operators. Third, the untwisted chain enlarges the norms of all conjugates by at most an explicit factor. The allowed errors, weighted by $\log p$, sum to at most the budget.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. That headline is a claim. Its authors report that every file compiles and that Lean's kernel accepts the proofs; a replay of that check is recorded in the handout when it reports; nothing was compiled for this note, and no mathematician has read the argument through. Nothing here says that the Riemann hypothesis is proved. This note treats one unit of the artifact, the folder of the columns: all 105 of its 105 declarations. Every statement below was compared with its Lean text, argument by argument. The proofs are given at the level of the structured proofs of the unit's dossier, which were read together with the Lean text; results of other units and of the background library are stated as *Inputs* with their owners, and steps that the formal text leaves to automation and that could not be replayed without Lean are named in §15. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 105 declarations.

1 The statements

The objects are defined in §2. In short: D is a record of admissible data for parameters $P = (N_0, d)$, with scales x, x_1, b and numbers m, r; $\mathrm{Col}(D)$ is the space of columns and $\mathrm{Col}^{\mathrm{ram}}(D)$ its subspace of ramified columns (Definitions 2.3 and 2.7); for a twist ϑ of D and a finitely supported function Ψ on tuples of translations, $\mathrm{B}_D(\vartheta, \Psi)$ is the chain of m theta lifts with data given by Ψ, followed by the restriction to the index

set $Y_m(D)$ (Input I4); $\mathrm{gain}(D,p)$ and $\mathrm{loss}(D,p)$ are the divisibility asked at p and the unit of allowed loss (unit 150), and $\mathrm{budget}(D) = f(D)\,a(D)\,(\log b)^3$.

Theorem A (short ramified columns span). In Setting 2.1, the complex vector space $\mathrm{Col}^{\mathrm{ram}}(D)$ is spanned by the ramified columns φ such that φ is $\exp(\mathrm{budget}(D))$-short: the values of φ are integral at every p-adic place, and $\|\sigma \circ \varphi(g)\|^2 \le \exp(\mathrm{budget}(D))$ for every automorphism σ of $\mathbb{C}$ and every point g.

Theorem B (divisibility of the chain at each prime). In Settings 2.1 and 2.2, let β be an integer with

$$\beta \;<\; [\,p \in \mathrm{NS}(D)\,] \cdot \mathrm{gain}(D,p) - \mathrm{err}(D,p) + 1.$$

Then there are a natural number $l \le \mathrm{err}(D,p)\cdot \dim_{\mathbb{C}} \mathrm{Col}(D)$ and an O_j-submodule S of $\mathrm{Col}(D)$ such that

(i) S has index dividing p^l in the module $\mathrm{Col}_j(D)$ of j-integral columns (Input I2), and

(ii) for every twist ϑ of D, every finitely supported complex function Ψ on the tuples of translations of D such that Ψ is good for (D,ϑ) and p is prime to $\mathrm{nrm}(\vartheta)$, and every $\varphi \in S$ that is a ramified column, the form $p^{-\beta}\cdot \mathrm{B}_D(\vartheta,\Psi)\varphi$ has j-gauge at most 1 at 1.

Theorem C (size of all conjugates of the untwisted chain). In Setting 2.1, let Ψ be a finitely supported complex function on the tuples of translations of D such that Ψ is good for $(D,1)$ for the trivial twist 1; let σ be an automorphism of $\mathbb{C}$, $\varphi \in \mathrm{Col}(D)$ and B a real number with $\|\sigma \circ \varphi(g)\|^2 \le \mathrm{e}^B$ for every $g \in G_{X_0(D)}$. Then for every $h \in G_{Y_m(D)}$

$$\|\sigma \circ (\mathrm{B}_D(1,\Psi)\varphi)(h)\|^2 \le \exp\Big(B + h_{\mathrm{row}}(D) + 2\sum_{p\in \mathrm{NS}(D)} \mathrm{gain}(D,p)\,\log p + \mathrm{budget}(D)\Big).$$

Theorem D (the allowed losses fit the budget). In Setting 2.1, for every finite set U of natural numbers, $\sum_{p\in U} \mathrm{err}(D,p)\cdot \log p \;\le\; \mathrm{budget}(D)$.

LEAN `Data.span_short_ramifiedColumns` · `Data.exists_indexDvd_Bmu_divisible` · `Data.weylNormSq_Bmu_le` · `Data.sum_allowedLoss_mul_log_le`

How the four fit together. The explanations of this paragraph are orientation; the deduction belongs to the unit of the endgame, which uses these four results, and was not read for this note. A row of the handout's Theorem A is, after the seesaw identity, of the form $\mathrm{B}_D(\vartheta,\Psi)\psi$ for a ramified column ψ, divided by a rational number that collects the powers $p^{\mathrm{gain}(D,p)}$ and a power of $N(D)$. Theorem A provides the columns ψ, Theorem C bounds the size of the rows at every conjugate,

and Theorem B bounds their denominators: at each prime the rows built from a submodule S of index dividing p^l, in the sense of Input I2 (a statement about matrices of determinant dividing p^l, not about the order of a quotient), are integral after division by p^β, and the exponents l, weighted by $\log p$, add up to at most $\dim \mathrm{Col}(D) \cdot \mathrm{budget}(D)$ by Theorem D. The number $h_{\mathrm{row}}(D)$ of Theorem C contains the term $-\#\mathrm{tops}(D) \cdot a(D) \log N(D)$: the restriction divides by a power of $\overline{\pi_N(D)}$, and this is how the level prime pays for the excess of size over divisibility. The error at a prime is three units of loss; one unit is $f(D)(\log b)^2 a(D)/p$, multiplied by m when $p \equiv \pm 1$ modulo m.

The mechanism at a prime. Let $p < x_1$ be inert or ramified in $K(P)$. A single lift is a finite sum of jets of theta series with complex multiplication, and by the unit on the CM curve a jet along a Schur matrix with L boxes is divisible by p to an exponent of the shape $(1/(p-1) - \varrho_d(p))L$ minus a sum of *coupling counts* (Input I9). Proposition 7.3 shows that this exponent, summed over the m lifts, is at least $\mathrm{gain}(D,p)$ up to one unit of loss, except for the *collisions*: pairs of top places exchanged by an odd power of $-p$. A collision with a small exponent can only occur when p is *served* (inert, not $\equiv \pm 1$ modulo m, and $-p$ of small odd order modulo N_0). For such p one chooses a set $\mathcal{L}$ of primes of $E(D)$ above p, one from each conjugate pair met by the tops, and applies at each of them the Hecke operator of $\mathrm{diag}(p, \dots, p, 1, \dots, 1)$ scaled by a power of p. On the image the divisibility is restored (Proposition 8.4), because the Hecke operator moves through every lift (Proposition 8.1) and changes the datum by a diagonal matrix that the jet bound absorbs (Proposition 8.2); and the image has small index (Proposition 9.2, whose content is a theorem of the unit on twisted Hecke operators). At the level prime itself the data of the chain have denominator $N(D)$, and a Fourier transform on the columns removes it (§10).

2 The setting

Conventions. $\mathbb{N} = \{0, 1, 2, \dots\}$. Where the formal text subtracts or divides natural numbers, the subtraction is truncated at 0 and the division is rounded down; such places are marked. $[\,\mathcal{C}\,]$ is 1 if the condition $\mathcal{C}$ holds and 0 otherwise. Throughout, E is a CM field with its complex conjugation $x \mapsto \overline{x}$, a CM type and Weil data (the idele and the splitting character that the Weil representation over E needs; they are those of the note on the CM field when $E = E(D)$). $\mathrm{Pl}(E)$ is the set of infinite places of E, and $\iota_\tau \colon E \to \mathbb{C}$ is the embedding of the CM type at $\tau \in \mathrm{Pl}(E)$. A *finite place* w is a non-zero prime ideal of the ring of integers $\mathcal{O}_E$; $\overline{w}$ is its conjugate, E_w the completion, and q_w the number of elements of the residue field. $\mathbb{A}_{E,\mathrm{f}}$ is the ring of finite adeles and $\widehat{\mathcal{O}}_E$ its subring of integral adeles. I and I' are finite index sets, and K denotes a subgroup of the group G_I of Input I1; a family $\varkappa$ of *column counts* is a function $(\tau, h) \mapsto \varkappa(\tau, h) \in \mathbb{N}$ on $\mathrm{Pl}(E) \times \mathbb{N}$, and a family $\mathfrak{e}$ of *determinant exponents* is a function $\mathrm{Pl}(E) \to \mathbb{Z}$. $\mathrm{Aut}(\mathbb{C})$ is the group of all field automorphisms of $\mathbb{C}$. For parameters $P = (N_0, d)$, $K(P) = \mathbb{Q}(\sqrt{-d})$ and $\chi_{K(P)}$ is its quadratic character, the Legendre symbol modulo d. A *p-adic place* is a prime number p with a ring homomorphism $j \colon \mathbb{C} \to \mathbb{C}_p$ (Setting 2.2). In a statement about a commutative ring R or a normed field, that structure is part of the statement.

Setting 2.1 (the data)**.** $P = (N_0, d)$ are parameters and D is a record of admissible data for P (the note on the admissible data), with real scales x, x_1, b and natural numbers m, r among its components. The functions of D are written with their argument: the exponent $\mu(D)$, the CM field $E(D)$ with its group $\mathrm{Pl}(D)$ of infinite places, $N_1(D)$, the number $f(D)$ of infinite places, $k(D) = r+1-m$, $t(D) = 5r$, $a(D)$, the sets $\mathrm{tops}(D)$ and $\mathrm{thick}(D)$, the nominal weight $w_D(\tau)$, the place $[\nu]_D \in \mathrm{Pl}(D)$ named by an integer ν, the ranks $n_i(D) = k(D) + i(t(D)+1)$, the weights $\mathrm{wt}_D(i,\tau)$ and $\mathrm{budget}(D) = f(D)\,a(D)\,(\log b)^3$. *Size comparisons* between such quantities (inequalities that hold because of the scale conditions $(\log b)^{100} \le x$, $x^{10^6} \le x_1$, $x_1^{10^6} \le b$ of the data) are quoted from the note on the admissible data as "by size".

Setting 2.2 (a p-adic place)**.** p is a prime number and $j\colon \mathbb{C} \to \mathbb{C}_p$ is a ring homomorphism into the completion $\mathbb{C}_p$ of an algebraic closure of $\mathbb{Q}_p$, with absolute value $|\cdot|_p$, $|p|_p = p^{-1}$, and valuation ring $\mathfrak{o}_p$. Put $O_j = \{z \in \mathbb{C} : \ |j(z)|_p \le 1\}$, a valuation ring of $\mathbb{C}$.

Inputs: the objects. The definitions of this unit rest on objects of the background library and of other units. They are recalled here, in the words of the dossier's readings, which were compared with the Lean definitions named in the LEAN lines.

Input I1 (algebraic forms; background library). Let I be a finite set. $G_I = \{g \in \mathrm{GL}_I(\mathbb{A}_{E,\mathrm{f}}) : \ g^* g = 1\}$ is the group of finite adelic points of the unitary group of the standard definite hermitian space E^I (g^* the conjugate transpose); $\Gamma_I \subset G_I$ is the subgroup of its rational points, the unitary matrices over E; $K_I = G_I \cap \mathrm{GL}_I(\widehat{\mathcal{O}}_E)$. For an integer a of E, $K_I(a)$ is the principal level, the $k \in K_I$ with all entries of $k-1$ in $a\widehat{\mathcal{O}}_E$; for a finite place w, $K_I[w]$ is the group of the $k \in K_I$ whose components away from w and $\overline{w}$ are 1. A *level* is an open subgroup K of K_I; $\mathrm{Cl}(K)$ is the finite set of classes $\Gamma_I \backslash G_I / K$; K is *free* if $\Gamma_I \cap gKg^{-1} = \{1\}$ for every $g \in G_I$.
$\mathrm{Wy}_I(\varkappa)$ is the finite set of *Weyl indices*: the families, over $\tau \in \mathrm{Pl}(E)$, of standard fillings with entries in I of the diagram with $\varkappa(\tau, h)$ columns of height h. The *weight representation* $\rho_{\varkappa,\mathfrak{e}}$ sends a family (g_τ) of invertible matrices indexed by I to $\prod_\tau \det(g_\tau)^{\mathfrak{e}(\tau)}$ times the Schur matrix of (g_τ), a square matrix indexed by $\mathrm{Wy}_I(\varkappa)$; Γ_I acts on $\mathbb{C}^{\mathrm{Wy}_I(\varkappa)}$ by $\gamma \mapsto \rho_{\varkappa,\mathfrak{e}}((\iota_\tau(\overline{\gamma}))_\tau)$. The number of boxes below height n' is $\mathrm{boxes}(\varkappa, n') = \sum_\tau \sum_{h<n'} h\,\varkappa(\tau, h)$, and the row of index ν of the diagram at τ, for rank n', has length $\sum_{\nu<h<n'} \varkappa(\tau, h)$.
$\mathrm{Alg}_I(\varkappa, \mathfrak{e})$ is the space of *algebraic forms* of weight $(\varkappa, \mathfrak{e})$: the functions $\varphi\colon G_I \to \mathbb{C}^{\mathrm{Wy}_I(\varkappa)}$ with open stabiliser under right translation and $\varphi(\gamma g) = \rho_{\varkappa,\mathfrak{e}}(\gamma)\varphi(g)$ for $\gamma \in \Gamma_I$. G_I acts on it by right translation, $(\mathrm{R}(g)\varphi)(g') = \varphi(g'g)$. For a free level K, evaluation at representatives of the classes is an isomorphism from the K-fixed forms onto the functions $\mathrm{Cl}(K) \to \mathbb{C}^{\mathrm{Wy}_I(\varkappa)}$; the form that takes the value v at the representative of one class and 0 at the others is a *delta form*.
Gauge. In Setting 2.2, for $g \in G_I$ and $\xi \in \mathbb{C}^{\mathrm{Wy}_I(\varkappa)}$, the number $\mathrm{gauge}_j^{\varkappa,\mathfrak{e}}(g;\xi)$ is the largest p-adic absolute value of a coordinate of $\rho_{\varkappa,\mathfrak{e}}((g_\tau^{-1})_\tau)\, j(\xi)$, where $g_\tau \in \mathrm{GL}_I(\mathbb{C}_p)$ is the image of g under the continuous extension to $\mathbb{A}_{E,\mathrm{f}}$ of the embedding $x \mapsto j(\iota_\tau(\overline{x}))$. A form φ *has j-gauge at most c at $d \in G_I$* if $\mathrm{gauge}_j^{\varkappa,\mathfrak{e}}(gd; \varphi(g)) \le c$ for every $g \in G_I$. The gauge is an ultrametric norm in ξ with $\mathrm{gauge}_j^{\varkappa,\mathfrak{e}}(g; z\xi) = |j(z)|_p\, \mathrm{gauge}_j^{\varkappa,\mathfrak{e}}(g;\xi)$, it does not change when g is multiplied on the right by an element that is integral and invertible at all primes above p, and for such g it is at most 1 exactly when all coordinates of $j(\xi)$ are integral.
Gram norm. $\|\xi\|^2$ is the real part of $\xi^* G \xi$, where G is the integer Gram matrix of Weyl's lattice in the weight $\varkappa$; it is positive definite, and its square root is a norm. Automorphisms of $\mathbb{C}$ act on vectors coordinate by coordinate.

Input I2 (index and type; unit 149, the core). Let O be a commutative ring, V an O-module, M and S submodules of V and $z \in O$. *S has index dividing z in M* if for every natural number n and all $\Phi_1, \dots, \Phi_n \in M$ there is an $n \times n$ matrix u over O whose determinant divides z and with $\sum_c u_{ac}\Phi_c \in S$ for every a. An O-linear endomorphism y of V *has type (z, s, c) on M*, for $z \in O$, a natural number s and a real number c, if $y(M) \subseteq M$ and there is a natural number $l \le c$ such that $y(M) + z^s M$ has index dividing z^l in M. *Types add*: if $y_1, \dots, y_n$ have types $(z, s, c_1), \dots, (z, s, c_n)$ on M, then $y_1 \cdots y_n$ has type $(z, s, c_1 + \cdots + c_n)$ on M.

LEAN unit 149: IndexDvd, HasType, HasType.prod

Input I3 (objects of the data; units 152 and 141). In Setting 2.1: for each natural number i, $X_i(D)$ is an index set with $n_i(D)$ elements, one of them distinguished as the *last*; $Y_m(D)$ is an index set with $n_m(D) - 1$ elements. $N(D)$ is a prime number with $N(D) \equiv 1$ modulo $N_1(D)\,d$ and $m \log b \le \log N(D) \le 30\,m \log b$, and $\pi_N(D)$ is an integer of $E(D)$ with $\pi_N(D)\,\overline{\pi_N(D)} = N(D)$. $g(D) = g_0 g_1$ is the product of the two primes of the data, and $\pi_g(D)$ is the integer of $K(P)$ in the data, with $\pi_g(D)\,\overline{\pi_g(D)} = g(D)$. A finite place w of $E(D)$ is *chosen* if $\overline{\pi_g(D)} \in w$. For a finite set I, the *chosen level* $K_I^{\mathrm{ch}}(D)$ is the group of the $k \in K_I$ that are congruent to 1 modulo every chosen place; it contains $K_I(\overline{\pi_g(D)})$, and if $|I| \le 2\,n_m(D)$, every subgroup of $K_I^{\mathrm{ch}}(D)$ is free. The column counts $\varkappa_D$, the determinant exponents $\mathrm{last}_D(i, \cdot)$, the counts $\mathrm{kept}_D(h)$ and $\varkappa_D^Y$ are those of the unit on the CM curve (Input I6).

A *twist* of D is a continuous character ϑ of the norm-one adeles of $E(D)$, trivial on the norm-one elements of $E(D)$ and of weight 0 at the infinite places, together with a finite set $Q(\vartheta)$ of finite places and characters ϑ_w of the residue fields (its *tame part*) such that $\vartheta(y) = \prod_w \vartheta_w(y \bmod w)$ for y with integral finite part and trivial infinite part; $\vartheta_w = 1$ for $w \notin Q(\vartheta)$ and $\vartheta_w \ne 1$ for $w \in Q(\vartheta)$; $\overline{w} \notin Q(\vartheta)$ for $w \in Q(\vartheta)$; and $\mathrm{nrm}(\vartheta) = \prod_{w \in Q(\vartheta)} \mathrm{q}_w$ is prime to $g(D)\,N(D)$. The trivial character with $Q = \emptyset$ is the trivial twist 1, and $\mathrm{nrm}(1) = 1$.

LEAN unit 141: Data.X, Data.Y, Data.N, Data.N_modEq_one, Data.log_N_mem_Icc, Data.π, Data.piGBar, Data.IsChosen, Data.TameChar, Data.Twist, Data.TameChar.levelNorm · unit 152: Data.chosenLevel, Data.classAut_eq_bot_of_le_chosenLevel

Input I4 (kernels, data and the chain; background library, units 141, 147, 150). In Setting 2.1, let ϑ be a twist of D and i a natural number. $\mathcal{W}_i(D)$ is the *finite part* of the model of the Weil representation for the space of homomorphisms from $E^{X_i(D)}$ to $E^{X_{i+1}(D)}$: the complex span of the translates $\mathrm{U}(y)\,\mathrm{vac}$ of the vacuum vector by the finite Heisenberg operators $\mathrm{U}(y)$, where y is a matrix with rows $X_{i+1}(D)$ and columns $X_i(D)$ over $\mathbb{A}_{E(D),\mathrm{f}}$. It contains the *integral vacuum* $\theta^{\circ}_{D,i}$, a scalar multiple of the vacuum (unit 150). For a set Σ of finite places, P^{Σ} is the projection of $\mathcal{W}_i(D)$ onto the vectors that are vacua at the places of Σ and their conjugates.
The *lift kernel* $\mathrm{k}_{D,\vartheta,i}$ consists of a representation $\omega_{D,\vartheta,i}$ of $G_{X_i(D)} \times G_{X_{i+1}(D)}$ on $\mathcal{W}_i(D)$ (the Weil representation of the pair, with the characters of the $(i+1)$-st lift twisted by $\vartheta^{\,i+1}$) and of a linear map $\Phi \mapsto \mathrm{jm}_{D,\vartheta,i}(\Phi)$ from $\mathcal{W}_i(D)$ to the linear maps $\mathbb{C}^{\mathrm{Wy}_{X_i(D)}(\varkappa_D)} \to \mathbb{C}^{\mathrm{Wy}_{X_{i+1}(D)}(\varkappa_D)}$: the matrix of the jets, along the Schur matrix of $\varkappa_D$, of the Taylor series of the theta function of Φ at the scale $\overline{\pi_g(D)} \cdot \mathrm{per}(P, \mu(D))$. The *lift* with datum Φ is the map $\mathrm{lift}_{D,\vartheta,i}(\Phi)\colon \mathrm{St}_i(D) \to \mathrm{St}_{i+1}(D)$,

$$\big(\mathrm{lift}_{D,\vartheta,i}(\Phi)\varphi\big)(h) = \int_{\Gamma_{X_i(D)}\backslash G_{X_i(D)}} \mathrm{jm}_{D,\vartheta,i}\big(\omega_{D,\vartheta,i}(g,h)\Phi\big)\varphi(g)\,\mathrm{d}g,$$

a finite sum over classes, the measure giving volume 1 to $K_i^{\mathrm{col}}(D)$. It is equivariant: $\mathrm{lift}_{D,\vartheta,i}(\omega_{D,\vartheta,i}(a,b)\Phi)\,\mathrm{R}(a) = \mathrm{R}(b)\,\mathrm{lift}_{D,\vartheta,i}(\Phi)$. For points $d \in G_{X_i(D)}$, $d' \in G_{X_{i+1}(D)}$ and a real number c, in Setting 2.2, $\mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(d, d'; c)$ is the set of the $\Phi \in \mathcal{W}_i(D)$ with

$$\mathrm{gauge}_j^{\varkappa_D,\mathrm{last}_D(i+1,\,\cdot\,)}(hd'; \mathrm{jm}_{D,\vartheta,i}(\omega_{D,\vartheta,i}(g,h)\Phi)\xi) \\ \leq\ \max(c,0)\cdot \mathrm{gauge}_j^{\varkappa_D,\mathrm{last}_D(i,\,\cdot\,)}(gd;\xi)$$

for all g, h and ξ; it is closed under addition, and $z\Phi$ lies in $\mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(d, d'; c')$ when Φ lies in $\mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(d, d'; c)$ and $|j(z)|_p\, c \leq c'$ (unit 150).
A *tuple of translations* of D is a family $\mathsf{x} = (\mathsf{x}_i)_{i\in\mathbb{N}}$ of matrices x_i with rows $X_{i+1}(D)$ and columns $X_i(D)$ over $\mathbb{A}_{E(D),\mathrm{f}}$; its i-th datum is $\mathrm{td}_D(\mathsf{x}, i) = \mathrm{U}(\mathsf{x}_i)\,\theta^{\circ}_{D,i} \in \mathcal{W}_i(D)$. For a family $\Phi = (\Phi_i)_i$ with $\Phi_i \in \mathcal{W}_i(D)$, the *chain* of n lifts is

$$\mathrm{C}_{D,\vartheta}(\Phi)_n = \mathrm{lift}_{D,\vartheta,n-1}(\Phi_{n-1}) \circ \ldots \circ \mathrm{lift}_{D,\vartheta,0}(\Phi_0)\colon\ \mathrm{St}_0(D) \to \mathrm{St}_n(D),$$

and for a family $\Phi^{(2)} = (\Phi^{(2)}_\nu)_\nu$ with $\Phi^{(2)}_\nu \in \mathcal{W}_{2\nu}(D) \otimes \mathcal{W}_{2\nu+1}(D)$ the *chain of n pairs* $\mathrm{C}^{(2)}_{D,\vartheta}(\Phi^{(2)})_n\colon \mathrm{St}_0(D) \to \mathrm{St}_{2n}(D)$ is the composite, for $\nu < n$, of the maps that depend linearly on $\Phi^{(2)}_\nu$ and equal $\mathrm{lift}_{D,\vartheta,2\nu+1}(\Phi') \circ \mathrm{lift}_{D,\vartheta,2\nu}(\Phi)$ for $\Phi^{(2)}_\nu = \Phi \otimes \Phi'$. For a finitely supported complex function Ψ on the tuples of translations,

$$\mathrm{B}_D(\vartheta, \Psi) = \mathrm{restr}_D \circ \Big(\sum_{\mathsf{x}} \Psi(\mathsf{x}) \cdot \mathrm{C}_{D,\vartheta}(\mathrm{td}_D(\mathsf{x},\,\cdot\,))_m\Big)\Big|_{\mathrm{Col}(D)}$$

with the restriction restr_D of Definition 2.4. In Setting 2.2, $\mathrm{Col}_j(D)$ is the O_j-module of the columns that have j-gauge at most 1 at 1.

LEAN background library: `Space.finitePart`, `Space.finHeisOp`, `Space.heisFinPart`, `Space.projOn`, `Kernel`, `Kernel.lift`, `Kernel.lift_equivariant`, `thetaKernel` · unit 141: `chain`, `chain₂`, `projOnFinPart` · unit 147: `Data.homX`, `Data.liftKernel`, `Data.Translations`, `Data.translateDatum`, `Data.chainComb`, `Data.Bμ`, `Data.integralColumns` · unit 150: `Parameters.intVacuum`, `Kernel.raises`, `Kernel.smul_mem_raises`

Input I5 (induced primes and marked sets; unit 147). In Settings 2.1 and 2.2, for $\tau \in \mathrm{Pl}(D)$ the prime $\mathfrak{l}_j(\tau)$ of $E(D)$ *induced* by τ is the set of the integers y of $E(D)$ with $|j(\iota_\tau(y))|_p < 1$; it lies above p. A finite set $\mathcal{L}$ of finite places of $E(D)$ is *marked* (for D, p and j) if (M1) $\bar{\mathfrak{l}} \notin \mathcal{L}$ for every $\mathfrak{l} \in \mathcal{L}$; (M2) if $\mathcal{L}$ is not empty, then p is served for D; (M3) every $\mathfrak{l} \in \mathcal{L}$ is $\mathfrak{l}_j(\tau)$ for some $\tau \in \mathrm{tops}(D)$; (M4) p is small and not split for D. It is a *full mark* if moreover, for every $\tau \in \mathrm{tops}(D)$, one of $\mathfrak{l}_j(\tau)$, $\overline{\mathfrak{l}_j(\tau)}$ lies in $\mathcal{L}$. For a finite set $\mathcal{L}$ of finite places put

$$\Xi_j(\mathcal{L}) = \{\tau \in \mathrm{Pl}(D) : \ \mathfrak{l}_j(\tau) \in \mathcal{L}\}, \quad A_D(\mathfrak{l}) = a(D) \cdot \#\{\tau \in \mathrm{tops}(D) : \ \mathfrak{l}_j(\tau) = \mathfrak{l}\},$$

and for a natural number i and $\tau \in \mathrm{Pl}(D)$

$$\mathrm{lc}_D(i,\tau) = \sum_{h < n_{i+1}(D),\, h \neq 1} \varkappa_D(\tau, h), \qquad \mathrm{lb}_D(i,\tau) = \sum_{h < n_{i+1}(D),\, h \neq 1} h\, \varkappa_D(\tau, h).$$

LEAN unit 147: `Data.inducedPlace`, `Data.IsMarked`, `Data.IsFullMark`, `Data.evenPlaces`, `Data.markExponent`, `Data.lowColumns`, `Data.lowBoxes`

Input I6 (the bookkeeping of the unit on the CM curve; unit 150). In Setting 2.1, for natural numbers p, h, i, e, a real number y, places $\tau, \tau' \in \mathrm{Pl}(D)$ and a finite set $\Xi \subseteq \mathrm{Pl}(D)$; a pair (e,p) is *live* if $e \geq 1$ and (e is odd or $p = d$):

$$\mathrm{ask}_{D,p}(y,\tau) = \frac{1-\chi_{K(P)}(p)}{2} \sum_{e\colon (e,p) \text{ live}} \Big(\frac{y}{p^e} - w_D([-p^e]_D \cdot \tau)\Big)_+,$$

$$\mathrm{forced}(D,p) = \sum_{\tau \in \mathrm{Pl}(D)} \mathrm{ask}_{D,p}(w_D(\tau),\tau),$$

$$\mathrm{gain}(D,p) = m\Big(\sum_{\tau \in \mathrm{tops}(D)} \mathrm{ask}_{D,p}(a(D),\tau) + k(D)\,\mathrm{forced}(D,p)\Big),$$

$$\mathrm{loss}(D,p) = f(D)\,(\log b)^2\,\frac{a(D)}{p} \cdot m^*,$$

where $(\cdot)_+$ is the positive part, and $m^* = m$ if p is short for D, $m^* = 1$ otherwise; *p is short for D* if m divides $p-1$ (truncated) or $p+1$; *p is small and not split for D* if $p < x_1$ and $\chi_{K(P)}(p) \neq 1$; $\mathfrak{r}(D,p)$ is the least natural number with $m \leq p^{\mathfrak{r}(D,p)}$ (for $p > 1$); $\Delta(D,p) = \mathfrak{r}(D,p)\,f(D)\,(n_m(D) + \mathfrak{r}(D,p))$; $\mathrm{jc}(D,p) = \lceil 2mf(D)a(D)/p \rceil$; $o_0(D,p)$ is the order of the class modulo N_0 of the place $[-p]_D$; *p is served for D* if $\chi_{K(P)}(p) = -1$, p is not short for D, and $o_0(D,p)$ is odd and at most $\mathfrak{r}(D,p)$. The pair (τ,e) *is a collision of p outside Ξ for D* if (e,p) is live and both τ and $[-p^e]_D \cdot \tau$ lie in $\mathrm{tops}(D) \setminus \Xi$, and $\mathrm{coll}(D,p,\Xi)$ is the sum of the numbers $a(D)/p^e$ over all the pairs (τ,e) that are collisions of p outside Ξ for D. For column counts $\varkappa$ on a set of places and a natural number n', with $\mathrm{one}_\tau = [\tau \notin \Xi]\,[1 < n']\,\varkappa(\tau,1)$, $\mathrm{low}_\tau = \sum_{h<n',h\neq 1} \varkappa(\tau,h)$ and $\mathrm{bx}_\tau = \sum_{h<n',h\neq 1} h\,\varkappa(\tau,h)$,

$$\mathrm{cc}_p(\varkappa,n';\Xi;\tau,\tau';e) = \min\Big(\frac{\mathrm{one}_\tau}{p^e},\, \mathrm{low}_{\tau'} + \mathrm{one}_{\tau'}\Big) + \frac{\mathrm{low}_\tau}{p^e} + \min\Big(\frac{\mathrm{bx}_\tau}{p^e},\, \mathrm{bx}_{\tau'}\Big).$$

The column counts of the data are $\varkappa_D(\tau,1) = [\tau \in \mathrm{tops}(D)]\,a(D)$, $\varkappa_D(\tau,k(D)) = \mathrm{wt}_D(1,\tau) - \lfloor (k(D)+t(D)+1)/2 \rfloor$ (truncated; for $k(D) \neq 1$), $\varkappa_D(\tau,h) = \mathrm{gap}(D) - (t(D)+1)$ for $h > k(D)$ with $h \equiv k(D)$ modulo $t(D)+1$, and $\varkappa_D(\tau,h) = 0$ otherwise, where $\mathrm{gap}(D) = 2r^8$; $\mathrm{last}_D(0,\tau) = 0$ and $\mathrm{last}_D(i,\tau) = \lfloor n_{i-1}(D)/2 \rfloor - \mathrm{wt}_D(i,\tau)$ for $i \geq 1$; $\mathrm{kept}_D(h) = r^8 - \lfloor (t(D)+1)/2 \rfloor$ (truncated) if $h \geq k(D)$ and $h \equiv k(D)$ modulo $t(D)+1$, and 0 otherwise; $\varkappa^Y_D(\tau,h) = \mathrm{kept}_D(h) + (\varkappa_D(\tau,h+1) - \mathrm{kept}_D(h+1))$. Finally $\varrho_d(p)$ is $1/(p^2-1)$ if $\chi_{K(P)}(p) = -1$, $1/(2(p-1))$ if $p = d$, and $1/(p-1)$ otherwise; for a prime p with $\chi_{K(P)}(p) \neq 1$ and a real number c,

$$\sum_{e\colon (e,p) \text{ live}} \frac{c}{p^e} = \frac{2}{1-\chi_{K(P)}(p)}\; c\,\Big(\frac{1}{p-1} - \varrho_d(p)\Big), \tag{1}$$

and the series defining $\mathrm{ask}_{D,p}(y,\tau)$ converges.

The definitions of this unit.

Definition 2.3 (the primes dividing $\pi_N(D)$; levels, columns, stages)**.** In Setting 2.1, let i be a natural number.

(a) $\mathrm{Pl}_\pi(D)$ is the finite set of the finite places $\mathfrak{p}$ of $E(D)$ with $\pi_N(D) \in \mathfrak{p}$.

(b) The *column level* $K_i^{\mathrm{col}}(D)$ is the group of the elements k of the chosen level $K^{\mathrm{ch}}_{X_i(D)}(D)$ whose last row is congruent to $(0, \dots, 0, 1)$ modulo $\pi_N(D)$: every entry of the last row of $k - 1$ lies in $\pi_N(D)\,\widehat{\mathcal{O}}_{E(D)}$.

(c) The space of *columns* $\mathrm{Col}(D)$ is the space of the forms φ in the space $\mathrm{Alg}_{X_0(D)}(\varkappa_D, \mathrm{last}_D(0, \cdot))$ that are fixed under right translation by $K_0^{\mathrm{col}}(D)$.

(d) The *stage* $\mathrm{St}_i(D)$ is the space $\mathrm{Alg}_{X_i(D)}(\varkappa_D, \mathrm{last}_D(i, \cdot))$.

LEAN `Data.piPlaces` · `Data.columnLevel` · `Data.Column` · `Data.Stage`

Definition 2.4 (branching and the restriction)**.** In Setting 2.1, let $\tau \in \mathrm{Pl}(D)$.

(a) lst_D is a chosen bijection from $Y_m(D)$ onto the set of the elements of $X_m(D)$ other than the last; both sets have $n_m(D) - 1$ elements.

(b) $\mathrm{bd}_D \colon G_{Y_m(D)} \to G_{X_m(D)}$ is the homomorphism $h \mapsto \mathrm{diag}(h, 1)$, the block h being placed through lst_D and the 1 at the last index.

(c) The *branching exponent* is the integer $\mathrm{be}_D(\tau) = \sum_{0<h<n_m(D)} \big(\varkappa_D(\tau, h) - \mathrm{kept}_D(h)\big) + \mathrm{last}_D(m, \tau)$.

(d) $\mathrm{Br}(D)$ is a chosen matrix with integer entries, with rows indexed by $\mathrm{Wy}_{Y_m(D)}(\varkappa_D^Y)$ and columns by $\mathrm{Wy}_{X_m(D)}(\varkappa_D)$, that has the properties provided by the branching theorem of the background library (branching from GL_{n+1} to GL_n with multiplicity one): (Br1) over every field of characteristic 0, for families (g_τ) of invertible matrices indexed by $Y_m(D)$ and of units (s_τ),

$$\mathrm{Br}(D) \cdot \rho_{\varkappa_D, \mathrm{last}_D(m,\cdot)}\big((\mathrm{diag}(g_\tau, s_\tau))_\tau\big) = \prod_\tau s_\tau^{\mathrm{be}_D(\tau)} \cdot \rho_{\varkappa_D^Y, \mathrm{last}_D(m,\cdot)}\big((g_\tau)_\tau\big) \cdot \mathrm{Br}(D);$$

(Br2) $\|\mathrm{Br}(D)\xi\|^2 \le L^{6L}\,\|\xi\|^2$ for every vector ξ and every natural number $L \ge \sum_\tau \sum_{k(D)\le h<n_m(D)-1} h\,\varkappa_D^Y(\tau, h)$; (Br3) a spanning property of the library, which this unit does not use.

(e) The *restriction* $\mathrm{restr}_D \colon \mathrm{St}_m(D) \to \mathrm{Alg}_{Y_m(D)}(\varkappa_D^Y, \mathrm{last}_D(m, \cdot))$ is the $\mathbb{C}$-linear map

$$(\mathrm{restr}_D\,\varphi)(h) = \prod_{\tau' \in \mathrm{Pl}(D)} \iota_{\tau'}\big(\overline{\pi_N(D)}\big)^{-\mathrm{be}_D(\tau')} \cdot \mathrm{Br}(D)\,\varphi(\mathrm{bd}_D(h)) \qquad (h \in G_{Y_m(D)}).$$

LEAN `Data.lastIndexEquiv` · `Data.borderU` · `Data.branchExp` · `Data.branching` · `Data.restrictToY` · the branching theorem is `exists_branching_matrix` of the background library; the catalogue of the handout records it as a known result (branching from $\mathrm{GL}(n+1)$ to $\mathrm{GL}(n)$ with multiplicity one), *reference to be confirmed*

That $\mathrm{restr}_D\,\varphi$ is again an algebraic form follows from (Br1), applied to a rational point γ of $G_{Y_m(D)}$ and the units $s_\tau = 1$; the formal definition contains this verification.

Definition 2.5 (short forms)**.** Let E be a CM field with a CM type, I a finite set, $\varkappa$ column counts and $\mathfrak{e}$ determinant exponents. For a real number B and a form $\varphi \in \mathrm{Alg}_I(\varkappa, \mathfrak{e})$ we say that φ is B-short if

(i) for every prime number p and every ring homomorphism $j\colon \mathbb{C} \to \mathbb{C}_p$, φ has j-gauge at most 1 at 1; and

(ii) $\|\sigma \circ \varphi(g)\|^2 \le B$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$ and every $g \in G_I$.

LEAN `IsShort`

Lemma 2.6 (a central element at a prime dividing $\pi_N(D)$)**.** *In Setting 2.1, let $\mathfrak{p} \in \mathrm{Pl}_\pi(D)$. There is a finite adele c of $E(D)$ with $c\overline{c} = 1$ such that: c is integral; $c_w = 1$ at every finite place w with $w \ne \mathfrak{p}$ and $\overline{w} \ne \mathfrak{p}$; and every natural number n for which $c_{\mathfrak{p}}^n - 1$ has $\mathfrak{p}$-adic absolute value less than 1 is divisible by $N(D) - 1$.*

LEAN `Data.exists_centralGen` · proof in §4

Definition 2.7 (central translations and ramified columns)**.** (a) Let E be a CM field with a CM type, I a finite set, $\varkappa$ column counts, $\mathfrak{e}$ determinant exponents, J a level of G_I and χ a character of J. The *central representation* is the representation $z \mapsto \mathrm{R}(z \cdot 1_I)$, by right translation by scalar matrices, of the group of the finite adeles z of E with $z\overline{z} = 1$ on the space of the forms $\varphi \in \mathrm{Alg}_I(\varkappa, \mathfrak{e})$ with $\mathrm{R}(k)\varphi = \chi(k)\varphi$ for all $k \in J$. (Scalar matrices commute with J, so this space is stable.)

(b) In Setting 2.1, for $\mathfrak{p} \in \mathrm{Pl}_\pi(D)$, $\mathfrak{c}_D(\mathfrak{p})$ is a chosen adele c with the properties of Lemma 2.6.

(c) In Setting 2.1, cen_D is the central representation of (a) on $\mathrm{Col}(D)$, that is, for $E = E(D)$, $I = X_0(D)$, the weight $(\varkappa_D, \mathrm{last}_D(0, \cdot))$, $J = K_0^{\mathrm{col}}(D)$ and $\chi = 1$.

(d) In Setting 2.1, for a finite set $\Sigma \subseteq \mathrm{Pl}_\pi(D)$, the endomorphism $\mathrm{ram}_D(\Sigma) = \prod_{\mathfrak{p}\in\Sigma}(1 - \mathrm{cen}_D(\mathfrak{c}_D(\mathfrak{p})))$ of $\mathrm{Col}(D)$; the factors commute.

(e) In Setting 2.1, the space of *ramified columns* $\mathrm{Col}^{\mathrm{ram}}(D)$ is the image of $\mathrm{ram}_D(\mathrm{Pl}_\pi(D))$.

LEAN `algFormCentralRep` · `Data.centralGen` · `Data.centralRep` · `Data.ramifyingOp` · `Data.ramifiedColumns`

Definition 2.8 (admissible translations, paired translates, good data)**.** In Setting 2.1:

(a) For a natural number q, $\mathrm{Adm}_D(q)$ is the set of the tuples of translations x such that, for every i, every entry of $\pi_g(D) \cdot \mathsf{x}_i$ is integral at every finite place w with $q \notin w$.

(b) For a family $v = (v_i)_{i\in\mathbb{N}}$ with $v_i \in \mathcal{W}_i(D)$ and a natural number ν,

$$\mathrm{pt}_D(v)_\nu = \sum_y \mathrm{U}(\mathrm{col}(-y/N))v_{2\nu} \otimes \mathrm{U}(\mathrm{row}(-\overline{y/N}))v_{2\nu+1} \ \in\ \mathcal{W}_{2\nu}(D) \otimes \mathcal{W}_{2\nu+1}(D),$$

where $N = N(D)$; y runs over the vectors indexed by $X_{2\nu+1}(D)$ with entries in $(\mathbb{Z}/N)^{\mathrm{Pl}_\pi(D)}$; y/N is the vector of finite adeles whose component at $\mathfrak{p} \in \mathrm{Pl}_\pi(D)$ is the least non-negative representative of $y_{\mathfrak{p}}$ divided by N, and 0 at the other places; $\mathrm{col}(z)$ is the matrix with rows $X_{2\nu+1}(D)$ and columns $X_{2\nu}(D)$ whose last column is z and whose other columns are 0; and $\mathrm{row}(z)$ is the matrix with rows $X_{2\nu+2}(D)$ and columns $X_{2\nu+1}(D)$ whose last row is z and whose other rows are 0.

(c) Let ϑ be a twist of D and Ψ a finitely supported complex function on the tuples of translations of D. We say that Ψ is good for (D, ϑ) if the following three conditions hold.

(G1) The support of Ψ lies in $\mathrm{Adm}_D(\mathrm{nrm}(\vartheta)\cdot N(D))$; for every x, every prime number ℓ prime to $\mathrm{nrm}(\vartheta)$ and every ring homomorphism $\iota\colon \mathbb{C}\to\mathbb{C}_\ell$, $|\iota(\Psi(\mathsf{x}))|_\ell \le 1$; and if $Q(\vartheta)=\emptyset$, then $\sum_{\mathsf{x}}|\sigma(\Psi(\mathsf{x}))|\le \exp(x^{60})$ for every $\sigma\in\mathrm{Aut}(\mathbb{C})$.
(G2) (*joint invariance*) For every family $(a_i)_{i\in\mathbb{N}}$ with $a_i\in K_i^{\mathrm{col}}(D)$ and $a_i=1$ for $i\ge m$, the tensor $\sum_{\mathsf{x}}\Psi(\mathsf{x})\cdot\bigotimes_{i<m}\mathrm{td}_D(\mathsf{x},i)$ in $\bigotimes_{i<m}\mathcal{W}_i(D)$ is fixed by $\bigotimes_{i<m}\omega_{D,\vartheta,i}(a_i,a_{i+1})$; in the formal text: the two tensors have the same image under every linear map.
(G3) (*the shape at N*) For every form $\varphi\in\mathrm{St}_0(D)$,

$$\sum_{\mathsf{x}}\Psi(\mathsf{x})\cdot \mathrm{C}_{D,\vartheta}(\mathrm{td}_D(\mathsf{x},\,\cdot\,))_m\,\varphi \\ = \sum_{\mathsf{x}}\Psi(\mathsf{x})\cdot \mathrm{C}^{(2)}_{D,\vartheta}(\nu\mapsto \mathrm{pt}_D(\mathrm{P}^{\mathrm{Pl}_\pi(D)}\mathrm{td}_D(\mathsf{x},\,\cdot\,))_\nu)_{m/2}\,\varphi.$$

LEAN `Data.admissibleTranslations` · `Data.pairTranslates` · `Data.IsGoodDatum` · with `IsAdmissibleCoeffs`, `IsJointlyInvariant`, `translateSum` of unit 141

In (G3) the formal text writes the number of pairs as $\lfloor m/2\rfloor-1+1$ and the number of lifts on the left as twice that; m is a power of 2 with $m\ge 2$, so these are $m/2$ and m. That good data exist, and that the rows of the handout are of the form $\mathrm{B}_D(\vartheta,\Psi)\psi$ for good Ψ, is proved in the unit on the seesaw; this unit only uses the three conditions.

Definition 2.9 (the jet exponent, the loss of a lift, the mark operators)**.** In Setting 2.1:

(a) For natural numbers p and i and a finite set $\Xi\subseteq\mathrm{Pl}(D)$, put $n'=n_{i+1}(D)$, $L=\mathrm{boxes}(\varkappa_D,n')$ and $l=\lfloor\log_p L\rfloor$ (which is 0 if $p\le 1$ or $L=0$). The *jet exponent* is the real number

$$\mathrm{je}_D(p,i,\Xi)=\Big(\frac{1}{p-1}-\varrho_d(p)\Big)L-f(D)\,n'^3\,(l+1) \\ +\frac{\chi_{K(P)}(p)-1}{2}\sum_{\substack{0\le e\le l\\ e\text{ odd or }p=d}}\ \sum_{\tau\in\mathrm{Pl}(D)}\mathrm{cc}_p(\varkappa_D,n';\Xi;\tau,[-p^e]_D\cdot\tau;e).$$

(b) In Setting 2.2, for a finite set $\mathcal{L}$ of finite places of $E(D)$ and a natural number i, the *loss of the lift* i is $\mathrm{ll}_{D,p}(\mathcal{L},i)=\mathfrak{r}(D,p)\sum_{\tau\in\Xi_j(\mathcal{L})}\mathrm{lc}_D(i,\tau)-\mathrm{je}_D(p,i,\Xi_j(\mathcal{L}))$.

(c) In Setting 2.2, for a marked set $\mathcal{L}$ and $\mathfrak{l}\in\mathcal{L}$, the *mark operator* $\Upsilon_{D,\mathcal{L}}(\mathfrak{l})$ is the O_j-linear endomorphism $\varphi\mapsto p^{A_D(\mathfrak{l})}\cdot T_{\mathfrak{l},\mathfrak{r}(D,p)}\varphi$ of $\mathrm{Col}(D)$, where $T_{\mathfrak{l},s}$ is the Hecke operator of the double coset of $\mathrm{diag}(\varpi 1_s,1)$ at the split place $\mathfrak{l}$ (Input I8); columns are fixed by $K_{X_0(D)}[\mathfrak{l}]$, and the operator preserves $\mathrm{Col}(D)$ (Lemma 6.5).

LEAN `Data.jetExponent` · `Data.liftLoss` · `Data.IsMarked.markOperator`

For $p=d$ the sum over e in (a) contains $e=0$; the formal text has it so.

Definition 2.10 (the height per row, the non-split primes, the allowed loss)**.** In Setting 2.1:

(a) The *height per row* is

$$h_{\mathrm{row}}(D) = m\Big(\sum_{\tau\in\mathrm{tops}(D)} (\mathrm{st}_D(a(D)) - \mathrm{Ask}_D(a(D),\tau)) + k(D)\,\mathsf{U}(D)\Big) - \#\mathrm{tops}(D)\cdot a(D)\cdot \log N(D),$$

where, for a natural number n, a real number y and a place τ,

$$\mathrm{st}_D(n) = \log n! - n\log(\Omega(P,\mu(D))/g(D)),$$
$$\mathrm{Ask}_D(y,\tau) = \sum_{\nu=1}^{a(D)} \lambda_{d,1}(\nu)\big(y/\nu - w_D([-\nu]_D\cdot\tau)\big)_+,$$
$$\mathsf{U}(D) = \sum_{\tau\in\mathrm{Pl}(D)} (\mathrm{st}_D(\mathrm{wt}_D(0,\tau)) - \mathrm{Ask}_D(w_D(\tau),\tau))$$

(the last is the cost of one direction; these are objects of unit 152 and of the overview).

(b) $\mathrm{NS}(D)$ is the finite set of the prime numbers $p < \lceil x_1\rceil$ with $\chi_{K(P)}(p) \neq 1$.

(c) For a natural number p, the *allowed loss* $\mathrm{err}(D,p)$ is $3\,\mathrm{loss}(D,p)$ if $p\in\mathrm{NS}(D)$; $4\,m\,f(D)\,b$ if $p\notin\mathrm{NS}(D)$ and $p = N(D)$; and 0 otherwise.

LEAN `Data.heightPerRow` · `Data.nonsplitPrimes` · `Data.allowedLoss` · unit 152: `Data.jetSize`, `Data.primeSum`, `Data.dirCost`

3 Levels and columns

Lemma 3.1 (the primes dividing $\pi_N(D)$)**.** *In Setting 2.1:*

(a) $\pi_N(D)\neq 0$.

(b) A finite place w of $E(D)$ lies in $\mathrm{Pl}_\pi(D)$ if and only if $\pi_N(D)\in w$.

(c) For every $\mathfrak{p}\in\mathrm{Pl}_\pi(D)$: $\overline{\mathfrak{p}}\notin\mathrm{Pl}_\pi(D)$, the residue field of $\mathfrak{p}$ has $N(D)$ elements, and $N(D)$ is a uniformiser at $\mathfrak{p}$. For every finite place w of $E(D)$: $N(D)\in w$ if and only if $w\in\mathrm{Pl}_\pi(D)$ or $\overline{w}\in\mathrm{Pl}_\pi(D)$.

(d) $\#\,\mathrm{Pl}_\pi(D) = f(D)$.

Proof. (a) and (b) follow from $\pi_N(D)\overline{\pi_N(D)} = N(D)\neq 0$ and the definition. (c) Since $N(D)\equiv 1$ modulo $N_1(D)\,d$, the prime $N(D)$ splits completely in $E(D)$ (unit 152): every place above it has residue field of $N(D)$ elements and is different from its conjugate, and a place above it contains exactly one of $\pi_N(D)$, $\overline{\pi_N(D)}$. (d) The same input gives a bijection between $\mathrm{Pl}(D)$ and the primes that contain $\pi_N(D)$. □

LEAN `Data.π_ne_zero` · `Data.mem_piPlaces` · `Data.isSplitLevel_piPlaces` · `Data.card_piPlaces` · inputs of unit 152: `Parameters.q_eq_of_modEq_one`, `Parameters.star_mem_iff`, `Parameters.nonempty_infinitePlace_equiv_finPlace`

Lemma 3.2 (the column levels)**.** *In Setting 2.1, let i be a natural number.*

(a) $K_{X_i(D)}(\overline{\pi_g(D)}\,\pi_N(D))\subseteq K_i^{\mathrm{col}}(D)$.

(b) $K_i^{\mathrm{col}}(D)$ *is a level: an open subgroup of* $K_{X_i(D)}$.

(c) $X_i(D)$ *has* $n_i(D)$ *elements.*

(d) $K_0^{\mathrm{col}}(D)$ *is free:* $\Gamma_{X_0(D)}\cap g\,K_0^{\mathrm{col}}(D)\,g^{-1} = \{1\}$ *for every* $g\in G_{X_0(D)}$.

(e) *An element k of $G_{X_i(D)}$ lies in $K_i^{\mathrm{col}}(D)$ if and only if $k \in K_{X_i(D)}^{\mathrm{ch}}(D)$ and, for every $\mathfrak{p} \in \mathrm{Pl}_\pi(D)$ and every index c, the entry of $k_{\mathfrak{p}} - 1$ in the last row and the column c lies in the maximal ideal at $\mathfrak{p}$.*

(f) *If w is a finite place of $E(D)$ with $N(D) \in w$, then neither w nor $\overline{w}$ is chosen.*

(g) *If S is a set of finite places of $E(D)$ such that $N(D) \in w$ for every $w \in S$, then every element of $K_{X_i(D)}$ whose components away from the places of S and their conjugates are 1 lies in $K_{X_i(D)}^{\mathrm{ch}}(D)$.*

(h) *If ℓ is a prime number with $\ell \neq N(D)$ and w a finite place of $E(D)$ with $\ell \in w$, then $N(D) \notin w$ and $\overline{w} \notin \mathrm{Pl}_\pi(D)$.*

(i) *In Setting 2.2, $|j(\overline{\pi_g(D)})|_p \leq 1$.*

Proof. (a) An element of the principal level of $\overline{\pi_g(D)}\pi_N(D)$ is congruent to 1 modulo the chosen places and modulo $\pi_N(D)$. (b) $K_i^{\mathrm{col}}(D)$ lies in $K_{X_i(D)}$ and contains the open group of (a). (c) is the definition of the index sets. (d) $K_0^{\mathrm{col}}(D)$ is a subgroup of the chosen level and $n_0(D) \leq 2n_m(D)$ (Input I3). (e) unfolds Definition 2.3(b) place by place: by Lemma 3.1(c), $\pi_N(D)$ is a uniformiser at the places of $\mathrm{Pl}_\pi(D)$ and a unit elsewhere. (f) A chosen place lies above g_0 or g_1, and these primes differ from $N(D)$ by size. (g) follows from (f): such an element is 1 at every chosen place. (h) A prime ideal contains only one prime number; the second claim is Lemma 3.1(c). (i) $\pi_g(D)$ is an algebraic integer, and ring homomorphisms preserve integrality. □

LEAN `Data.principalLevel_le_columnLevel` · `Data.isLevel_columnLevel` · `Data.card_X` · `Data.classAut_columnLevel_eq_bot` · `Data.mem_columnLevel` · `Data.not_isChosen_of_N_mem` · `Data.mem_chosenLevel_of_supportedOn` · `Data.notMem_piPlaces_of_ne` · `Data.norm_star_piG_le_one`

Lemma 3.3 (two bounds for the weight)**.** *In Setting 2.1, let $\tau \in \mathrm{Pl}(D)$.*

(a) *$\varkappa_D(\tau, 1) - 2b \leq \mathrm{be}_D(\tau)$, as real numbers.*

(b) *$\sum_{h<\#X_0(D)} h\,\varkappa_D(\tau, h) \leq a(D)$.*

Proof. (a) In $\mathrm{be}_D(\tau)$ the term $h = 1$ of the sum is $\varkappa_D(\tau, 1)$, the other terms are non-negative, and $\mathrm{last}_D(m, \tau) \geq -\mathrm{wt}_D(m, \tau) \geq -2b$ by the bound $\mathrm{wt}_D(i, \tau) \leq 2b$ for $i \leq 2m$ of unit 152. (b) $X_0(D)$ has $k(D)$ elements, and among the heights $h < k(D)$ only $h = 1$ has columns, namely $a(D)$ at the tops and none elsewhere. □

LEAN `Data.le_branchExp` · `Data.sum_height_mul_kappa_le` · input of unit 152: `Data.w_le_two_mul_b`

4 Short forms span

Lemma 4.1 (differences of translates)**.** *Let E be a CM field with a CM type, I a finite set, $\varkappa$ column counts and $\mathfrak{e}$ determinant exponents. Let B be a real number, $k \in K_I$ and $\varphi \in \mathrm{Alg}_I(\varkappa, \mathfrak{e})$. If φ is B-short, then $(\varphi - \mathrm{R}(k)\varphi)$ is $4B$-short.*

Proof. At a p-adic place the forms of gauge at most 1 at 1 form a module, and the translate $\mathrm{R}(k)\varphi$ is one of them: its value at g is $\varphi(gk)$, and the gauge of a vector at g equals its gauge at gk, because the gauge is invariant under K_I (Input I1). For $\sigma \in \mathrm{Aut}(\mathbb{C})$ and a point g put $\xi = \sigma \circ \varphi(g)$, $\xi' = \sigma \circ \varphi(gk)$; by the parallelogram law for the Gram form, $\|\xi - \xi'\|^2 \leq \|\xi - \xi'\|^2 + \|\xi + \xi'\|^2 = 2\|\xi\|^2 + 2\|\xi'\|^2 \leq 4B$. □

LEAN `IsShort.sub_translate`

Input I7 (short bases, delta forms, Schur matrices; background library). Let E be a CM field with f infinite places, I a finite set and $N' \geq 1$ a natural number that lies in the different of E over $\mathbb{Q}$. (i) For every $g \in G_I$ there is an invertible matrix $Y(g)$ over E, indexed by I, such that $g^{-1}Y(g)$ has entries in $\widehat{\mathcal{O}}_E$ and every entry of $Y(g)$ has absolute value at most $6N'(f|I|)^2$ at every embedding $E \to \mathbb{C}$. (ii) For a free level K the delta form with value v at the representative g_c of a class has, at every point, j-gauge at most $\mathrm{gauge}_j^{\varkappa,\mathfrak{e}}(g_c; v)$, and its values ξ satisfy $\|\sigma \circ \xi\|^2 \leq \|\sigma \circ v\|^2$ for $\sigma \in \mathrm{Aut}(\mathbb{C})$. (iii) The *evaluation vectors* $\mathrm{ev}(y) \in \mathbb{C}^{\mathrm{Wy}_I(\varkappa)}$, the values at a point y of the basis polynomials of the weight $\varkappa$, span $\mathbb{C}^{\mathrm{Wy}_I(\varkappa)}$ when y runs over the points whose coordinates are roots of unity; they have integer polynomial coordinates, and $\rho_{\varkappa,0}(z)\,\mathrm{ev}(y)$ is the evaluation vector at the transformed point $z \cdot y$. In particular $\mathrm{ev}(y) = \rho_{\varkappa,0}(\mathrm{sq}(y))\,\mathrm{ev}(1)$, where $\mathrm{sq}(y)$ is the family of the square matrices formed by the first $|I|$ columns of y at each place and $\mathrm{ev}(1)$ is the evaluation vector at the unit point; and $\|\mathrm{ev}(1)\|^2 = 1$. (iv) For families $z = (z_\tau)$ of complex matrices indexed by I there are real numbers $c_{\tau,\nu} \geq 0$, with $\sum_\nu c_{\tau,\nu}$ at most the sum of the squares of the absolute values of the entries of z_τ, such that the Schur matrix of z multiplies $\|\cdot\|^2$ by at most $\prod_\tau \prod_{\nu<|I|} c_{\tau,\nu}^{\,l(\tau,\nu)}$, where $l(\tau,\nu)$ is the length of the row of index ν at τ.

LEAN background library: `Space.exists_short_basis_stdSpace`, `weylGauge_deltaForm_le`, `weylNormSq_deltaForm_le`, `PolyRep.ext_weylEval`, `schur_mulVec_weylEval_of_detExp_zero`, `PolyRep.schur_squarePart_mulVec`, `PolyRep.weylNormSq_weylEval_permArray`, `weylNormSq_schur_le`; the catalogue classes them as elementary and gives no reference for them: *reference to be confirmed*; the header of the file of the last one names the contravariant form on Weyl's lattice

Proposition 4.2 (short forms span the forms of a free level)**.** *Let E be a CM field with a CM type, I a non-empty finite set, $\varkappa$ column counts and $\mathfrak{e}$ determinant exponents. Let K be a level of G_I that is free, $N' \geq 1$ a natural number that lies in the different of the ring of integers of E over $\mathbb{Z}$, M a natural number with*

$$|I| \cdot \#\,\mathrm{Pl}(E) + \mathrm{boxes}(\varkappa, |I|) \;\leq\; M,$$

and B a real number with $\left(6N'(\#\,\mathrm{Pl}(E)\cdot|I|)^2\right)^{6M} \leq B$. Then the space of the K-fixed forms in $\mathrm{Alg}_I(\varkappa,\mathfrak{e})$ is spanned over $\mathbb{C}$ by its elements φ with φ is B-short.

Proof. Put $R = 6N'(f|I|)^2$ with $f = \#\,\mathrm{Pl}(E)$. By Input I1 every K-fixed form is a sum of delta forms, so it suffices to treat the delta forms at one class, with representative g. Take the matrices $Y(\,\cdot\,)$ of Input I7(i). For a ring homomorphism ϕ from $\mathbb{C}$ to a normed field, write ϕ_τ for the embedding $y \mapsto \phi(\iota_\tau(\overline{y}))$ of E and put

$$A_\phi = \prod_\tau \det \phi_\tau(Y(g^{\mathfrak{e}(\tau)})) \cdot \rho_{\varkappa,0}((\phi_\tau(Y(g)))_\tau).$$

The matrix $A = A_{\mathrm{id}}$ is invertible, so by Input I7(iii) the vectors $A\,\mathrm{ev}(y)$, y with coordinates roots of unity, span $\mathbb{C}^{\mathrm{Wy}_I(\varkappa)}$; and $\phi \circ (A\,\mathrm{ev}(y)) = A_\phi\,\mathrm{ev}(\phi \circ y)$. It remains to show that the delta form with value $A\,\mathrm{ev}(y)$ is B-short. *At a p-adic place j:* by Input I7(ii) its gauge is at most $\mathrm{gauge}_j^{\varkappa,\mathfrak{e}}(g; A\,\mathrm{ev}(y))$, the largest absolute value of a coordinate of

$$\prod_\tau \det\left((g^{\mathfrak{e}(\tau)})_\tau^{-1}\, j_\tau Y(g^{\mathfrak{e}(\tau)})\right) \cdot \rho_{\varkappa,0}\left((g_\tau^{-1}\, j_\tau Y(g))_\tau\right)\mathrm{ev}(j \circ y).$$

The matrices $g^{-1}Y(g)$ are integral, so the determinants and the Schur matrix have integral entries, and $\mathrm{ev}(j\circ y)$ is integral because j maps roots of unity to units. *At $\sigma\in\mathrm{Aut}(\mathbb{C})$:* by Input I7(ii) the values ξ of the delta form have $\|\sigma\circ\xi\|^2\le\|A_\sigma\,\mathrm{ev}(\sigma\circ y)\|^2$. By Input I7(iii),

$$A_\sigma\,\mathrm{ev}(\sigma\circ y)=\prod_\tau \det\sigma_\tau(Y(g^{\mathfrak{e}(\tau)}))\cdot\rho_{\varkappa,0}(z)\,\mathrm{ev}(1),\qquad z=\mathrm{sq}((\sigma_\tau(Y(g)))_\tau\cdot(\sigma\circ y)),$$

and $\|\mathrm{ev}(1)\|^2=1$. Three factors remain. *The determinants*: the entries of $\sigma_\tau(Y(\,\cdot\,))$ have absolute value at most R, so each determinant has absolute value at most $(|I|R)^{|I|}\le R^{2|I|}$ (note $|I|\le R$), and the squares of the f determinants contribute at most $R^{4f|I|}$. *The Schur matrix*: an entry of z_τ is a sum of $|I|$ products of an entry of $\sigma_\tau(Y(g))$ with a root of unity, so the sum of the squares of the absolute values of the entries of z_τ is at most $|I|^2(|I|R)^2\le R^4$; by Input I7(iv) every $c_{\tau,\nu}$ is at most R^4, and since the row lengths $l(\tau,\nu)$ at all places add up to $\mathrm{boxes}(\varkappa,|I|)$, the Schur matrix multiplies $\|\cdot\|^2$ by at most $R^{4\,\mathrm{boxes}(\varkappa,|I|)}$. *The evaluation vector* $\mathrm{ev}(1)$ has norm 1. Altogether, by the hypothesis on M,

$$\|\sigma\circ\xi\|^2\;\le\;R^{4f|I|+4\,\mathrm{boxes}(\varkappa,|I|)}\;\le\;R^{4M}\;\le\;R^{6M}\;\le\;B.$$

(The formal text arranges the same three bounds against R^{6M}, which leaves room.) □

LEAN `span_isShort_eq_top`

Proof of Lemma 2.6. By Lemma 3.1(c) the residue field at $\mathfrak{p}$ has $N(D)$ elements, so its group of units is cyclic of order $N(D)-1$. Choose a unit y of the ring of integers of the completion at $\mathfrak{p}$ whose residue generates this group, regard it as an idele with component y at $\mathfrak{p}$ and 1 elsewhere, and put $c=y/\overline{y}$. Then $c\,\overline{c}=1$, c is integral, and c is 1 away from $\mathfrak{p}$ and $\overline{\mathfrak{p}}$. Since $\overline{\mathfrak{p}}\neq\mathfrak{p}$, the component of c at $\mathfrak{p}$ is y; if y^n-1 lies in the maximal ideal, the residue of y has order dividing n, so $N(D)-1$ divides n. □

Lemma 4.3 (the central elements act on columns)**.** *In Setting 2.1, let $\mathfrak{p}\in\mathrm{Pl}_\pi(D)$.*

(a) For every finite set I, the scalar matrix $\mathfrak{c}_D(\mathfrak{p})\cdot 1_I$ lies in $K_I[\mathfrak{p}]$.

(b) For every $\varphi\in\mathrm{Col}^{\mathrm{ram}}(D)$ there is a column $\varphi'\in\mathrm{Col}(D)$ with $\varphi=\varphi'-\mathrm{R}(\mathfrak{c}_D(\mathfrak{p})\cdot 1_{X_0(D)})\varphi'$.

Proof. (a) $\mathfrak{c}_D(\mathfrak{p})$ is integral of norm one and is 1 away from $\mathfrak{p}$, $\overline{\mathfrak{p}}$ (Lemma 2.6). (b) $\varphi=\mathrm{ram}_D(\mathrm{Pl}_\pi(D))\varphi_0$ for a column φ_0; split off the factor at $\mathfrak{p}$ and take $\varphi'=\mathrm{ram}_D(\mathrm{Pl}_\pi(D)\setminus\{\mathfrak{p}\})\varphi_0$. □

LEAN `Data.scalarFin_centralGen_mem` · `Data.exists_eq_sub_centralGen`

Lemma 4.4 (few columns are fixed by a central element)**.** *In Setting 2.1, for every $\mathfrak{p}\in\mathrm{Pl}_\pi(D)$,*

$$\dim_{\mathbb{C}}\ker(1-\mathrm{cen}_D(\mathfrak{c}_D(\mathfrak{p})))\;\le\;(N(D)-1)^{-1}\cdot\dim_{\mathbb{C}}\mathrm{Col}(D).$$

Proof. Let z be the scalar matrix of $\mathfrak{c}_D(\mathfrak{p})$ and K the group generated by $K_0^{\mathrm{col}}(D)$ and z. By Lemma 4.3(a) and Lemma 3.2(g), K lies in the chosen level; so K is a level, and both K and $K_0^{\mathrm{col}}(D)$ are free (Input I3). A column fixed by z is fixed by K. For free levels the dimension of the space of fixed forms is the number of classes times the dimension of the weight (Input I1), and each class of K consists of $[K:K_0^{\mathrm{col}}(D)]$ classes of $K_0^{\mathrm{col}}(D)$. Hence the kernel has dimension at most $\dim\mathrm{Col}(D)/[K:K_0^{\mathrm{col}}(D)]$. Some power z^n with $1\le n\le[K:K_0^{\mathrm{col}}(D)]$ lies in $K_0^{\mathrm{col}}(D)$; by Lemma 3.2(e) its

component at $\mathfrak{p}$ is congruent to 1 modulo $\mathfrak{p}$, so $N(D)-1$ divides n by Lemma 2.6. Therefore $[K : K_0^{\mathrm{col}}(D)] \geq N(D)-1$. □

LEAN `Data.finrank_ker_one_sub_centralGen_le`

Proposition 4.5 (the ramifying operator)**.** *In Setting 2.1, let Σ be a finite subset of $\mathrm{Pl}_\pi(D)$ and W a complex subspace of $\mathrm{Col}(D)$. Then*

$$\dim_{\mathbb{C}} \mathrm{ram}_D(\Sigma)^{-1}(W) \;\leq\; \dim_{\mathbb{C}} W + \#\Sigma \cdot (N(D)-1)^{-1} \cdot \dim_{\mathbb{C}} \mathrm{Col}(D),$$

and for every real number B and every $\varphi \in \mathrm{Col}(D)$ with φ is B-short,

$$\mathrm{ram}_D(\Sigma)\varphi \text{ is } 4^{\#\Sigma}B\text{-short.}$$

Proof. Induction on Σ; for $\Sigma = \emptyset$ the operator is the identity. Adding a place $\mathfrak{p}$ composes with $1 - \mathrm{cen}_D(\mathfrak{c}_D(\mathfrak{p}))$. The preimage of a subspace under a linear map has dimension at most the dimension of the subspace plus that of the kernel, which Lemma 4.4 bounds; and by Lemmas 4.3(a) and 4.1 the new factor multiplies the bound of shortness by 4. □

LEAN `Data.ramifyingOp_finrank_comap_and_short`

For $W = 0$ and $\Sigma = \mathrm{Pl}_\pi(D)$ the first claim says that the kernel of $\mathrm{ram}_D(\mathrm{Pl}_\pi(D))$ has dimension at most $f(D)\dim \mathrm{Col}(D)/(N(D)-1)$: the ramified columns have nearly full dimension. The unit on the filling (Theorem B of the handout) uses the proposition for its count of dimensions.

Proof of Theorem A. Put $B' = \exp(\mathrm{budget}(D))/4^{f(D)}$. Apply Proposition 4.2 to $E = E(D)$, $I = X_0(D)$, the weight $(\varkappa_D, \mathrm{last}_D(0,\cdot))$, the level $K_0^{\mathrm{col}}(D)$, which is free by Lemma 3.2(d), the number $N' = N_1(D)\,d$, which lies in the different of $E(D)$ (unit 152), and $M = k(D)\,f(D) + f(D)\,a(D)$, which is admissible by Lemma 3.3(b). The inequality $(6N'(f(D)k(D))^2)^{6M} \leq B'$ holds by size. So $\mathrm{Col}(D)$ is spanned by columns φ with φ is B'-short. The operator $\mathrm{ram}_D(\mathrm{Pl}_\pi(D))$ maps $\mathrm{Col}(D)$ onto $\mathrm{Col}^{\mathrm{ram}}(D)$, and by Proposition 4.5 and Lemma 3.1(d) it maps such φ to ramified columns that are $4^{f(D)}B'$-short, that is, $\exp(\mathrm{budget}(D))$-short. The image of a spanning set spans the image. □

5 The chain as a sum over classes

Setting 5.1 (a good datum at a p-adic place)**.** Settings 2.1 and 2.2 hold; ϑ is a twist of D, and Ψ is a finitely supported complex function on the tuples of translations of D such that Ψ is good for (D,ϑ); and p is prime to $\mathrm{nrm}(\vartheta)$.

Input I8 (standard data, Hecke operators, sums over classes; units 150, 141 and the background library). (i) In Settings 2.1 and 2.2, for an integer δ of $K(P)$ and a set S of finite places of $E(D)$, $\mathrm{Lat}(\delta;S)$ is the group of the matrices y over $\mathbb{A}_{E(D),\mathrm{f}}$ (of any fixed shape) such that every entry of δy is integral at every place of S; and $\mathrm{Std}_\delta(D,i)$ is the O_j-submodule, of the model that contains $\mathcal{W}_i(D)$, generated by the vectors $\mathrm{U}(y)\theta^\circ_{D,i}$ with $y\in\mathrm{Lat}(\delta;\{w:\ p\in w\})$. If $\delta\neq 0$ and $\Phi\in\mathrm{Std}_\delta(D,i)$, then for every complex number c, with the kernel taken at the scale $c\cdot\mathrm{per}(P,\mu(D))$, Φ multiplies gauges at the point 1 by at most $\left(|j(c)|_p/|j(\bar\delta\, d)|_p\right)^L$, $L=\mathrm{boxes}(\varkappa_D,n_{i+1}(D))$; for the lift kernel ($c=\overline{\pi_g(D)}$) this reads $\Phi\in\mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(1,1;(|j(\overline{\pi_g(D)})|_p/|j(\bar\delta d)|_p)^L)$.
(ii) Let w be a finite place of E with $\overline{w}\neq w$ and I a finite set. The group $\mathrm{GL}_I(E_w)$ embeds in G_I, an element g going to the point with component g at w, the component at $\overline{w}$ that unitarity forces, and 1 elsewhere; for a family $(g_w)_{w\in S}$ over a set S of such places, no two conjugate, $\mathrm{at}(g)$ is the product of these points. For a natural number s, the *basic double coset of index s* at w is the set of the $g\in\mathrm{GL}_I(E_w)$ such that g and ϖg^{-1} are integral and $\det g$ has valuation s (ϖ a uniformiser); for $s\le|I|$ it is the double coset of $\mathrm{diag}(\varpi 1_s,1)$ under the integral invertible matrices. On the vectors of a representation of G_I that are fixed by $K_I[w]$, the Hecke operator $T_{w,s}$ is the sum of the translates by representatives of the left cosets of the integral invertible matrices in this double coset; it preserves the vectors fixed by a group that contains $K_I[w]$ and commutes with every operator that commutes with the group at w.
(iii) In Setting 2.1, let ϑ be a twist, Ψ a finitely supported function on the tuples of translations, and $\Phi=(\Phi_{\mathsf{x},i})$ a family with $\Phi_{\mathsf{x},i}\in\mathcal{W}_i(D)$. The combination $\sum_{\mathsf{x}}\Psi(\mathsf{x})\bigotimes_{i<m}\Phi_{\mathsf{x},i}$ is *jointly invariant* if it satisfies condition (G2) of Definition 2.8 with $\Phi_{\mathsf{x},i}$ in place of $\mathrm{td}_D(\mathsf{x},i)$. Suppose that it is, that φ is a column, and that $\mathcal{C}_0,\dots,\mathcal{C}_m$ are properties of pairs (point, vector) such that $\mathcal{C}_0(g,\varphi(g))$ holds for all g and $\mathcal{C}_i(g,\xi)$ implies $\mathcal{C}_{i+1}(h,\mathrm{jm}_{D,\vartheta,i}(\omega_{D,\vartheta,i}(g,h)\Phi_{\mathsf{x},i})\xi)$ for x in the support, $i<m$ and all g,h. Then for every point h, the vector $\sum_{\mathsf{x}}\Psi(\mathsf{x})(\mathrm{C}_{D,\vartheta}(\Phi_{\mathsf{x}})_m\varphi)(h)$ is a sum of $\prod_{i<m}\#\mathrm{Cl}(K_i^{\mathrm{col}}(D))$ vectors of the form $\sum_{\mathsf{x}}\Psi(\mathsf{x})\beta(\bigotimes_{i<m}\Phi_{\mathsf{x},i})$, with β linear and $\mathcal{C}_m(h,\beta(\bigotimes_{i<m}\Phi_{\mathsf{x},i}))$ for every x in the support.

LEAN unit 150: `Parameters.integralAfter`, `Parameters.standardData`, `Parameters.mem_raises_of_standardData` · background library: `atSplit`, `atSplits`, `basicDoubleCoset`, `heckeSplit`, `map_heckeSplit` · unit 141: `IsJointlyInvariant`, `IsJointlyInvariant.sum_chain_mem_nsmul`

The reason for (iii) is that a lift is a finite sum over the classes of its level, each term being linear in the datum; m lifts give a sum over tuples of classes, and joint invariance makes the sum of the terms independent of the representatives, which is what allows one linear map β for all x. The levels are free because they lie in the chosen level (Input I3).

Lemma 5.2 (integrality of translations)**.** *In Setting 2.1:*

(a) Let q and i be natural numbers, $\mathsf{x}\in\mathrm{Adm}_D(q)$, δ an integer of $K(P)$, and S a set of finite places of $E(D)$ such that every $w\in S$ satisfies $q\notin w$ and ($\delta=\pi_g(D)$ or $\overline{w}$ is not chosen). Then $\mathsf{x}_i\in\mathrm{Lat}(\delta;S)$.

(b) *Let* x *be a tuple of translations,* i *a natural number and* S *a set of finite places of* $E(D)$ *such that* $\mathsf{x}_i \in \mathrm{Lat}(1; S \cup \overline{S})$*, where* $\overline{S}$ *is the set of the conjugates of the places of* S*. Then* $\mathrm{P}^S \mathrm{td}_D(\mathsf{x}, i) = \mathrm{td}_D(\mathsf{x}, i)$*.*

Proof. (a) At $w \in S$ the entries of $\pi_g(D)\mathsf{x}_i$ are integral, by the definition of $\mathrm{Adm}_D(q)$. If $\delta = \pi_g(D)$ this is the claim. Otherwise $\overline{\pi_g(D)} \notin \overline{w}$, that is, $\pi_g(D) \notin w$: so $\pi_g(D)$ is a unit at w, the entries of x_i are integral at w, and so are those of $\delta\mathsf{x}_i$. (b) The datum is the translate of a multiple of the vacuum by a matrix that is integral at $S \cup \overline{S}$, and such a translate is again a vacuum at these places (a property of the projection, from the library). □

LEAN `Data.mem_integralAfter` · `Data.projOn_translateDatum`

Lemma 5.3 (the data of a good datum are standard)**.** *In Setting 5.1, assume* $p \neq N(D)$*. Let* x *be in the support of* Ψ*,* i *a natural number and* δ *an integer of* $K(P)$ *such that* $\delta = \pi_g(D)$ *or* p *does not divide* $g(D)$*. Then* $\mathrm{td}_D(\mathsf{x}, i) \in \mathrm{Std}_\delta(D, i)$*.*

Proof. By (G1), $\mathsf{x} \in \mathrm{Adm}_D(\mathrm{nrm}(\vartheta)N(D))$. Let w be a place above p. Then $\mathrm{nrm}(\vartheta)N(D) \notin w$, because p is prime to $\mathrm{nrm}(\vartheta)$ and $p \neq N(D)$. If p does not divide $g(D)$, then $\overline{w}$, which also lies above p, is not chosen. So Lemma 5.2(a) gives $\mathsf{x}_i \in \mathrm{Lat}(\delta; \{w : p \in w\})$, and the datum is one of the generators of $\mathrm{Std}_\delta(D, i)$. □

LEAN `Data.IsGoodDatum.translateDatum_mem_standardData`

Lemma 5.4 (the chain is a plain sum)**.** *In Setting 2.1, let* ϑ *be a twist of* D*,* Ψ *a finitely supported complex function on the tuples of translations of* D*, and* $\Phi = (\Phi_{\mathsf{x},i})$ *a family of data* $\Phi_{\mathsf{x},i} \in \mathcal{W}_i(D)$ *such that* $\sum_{\mathsf{x}} \Psi(\mathsf{x}) \bigotimes_{i<m} \Phi_{\mathsf{x},i}$ *is jointly invariant. For every natural number* i *let* N_i *be a real function of a point of* $G_{X_i(D)}$ *and a vector, and* $r_i \geq 0$ *a real number, such that for every* x *in the support of* Ψ*, every* $i < m$ *and all* g*,* h*,* ξ

$$\mathrm{N}_{i+1}(h, \mathrm{jm}_{D,\vartheta,i}(\omega_{D,\vartheta,i}(g,h)\Phi_{\mathsf{x},i})\xi) \;\leq\; r_i \cdot \mathrm{N}_i(g, \xi).$$

Let $\varphi \in \mathrm{Col}(D)$ *and let* B *be a real number with* $\mathrm{N}_0(g, \varphi(g)) \leq B$ *for all* g*, and let* g *be a point of* $G_{X_m(D)}$*. Then there are linear maps* β_c*, for* $1 \leq c \leq \prod_{i<m} \#\mathrm{Cl}(K_i^{\mathrm{col}}(D))$*, from* $\bigotimes_{i<m} \mathcal{W}_i(D)$ *to* $\mathbb{C}^{\mathrm{Wy}_{X_m(D)}(\varkappa_D)}$ *such that* $\mathrm{N}_m(g, \beta_c(\bigotimes_{i<m} \Phi_{\mathsf{x},i})) \leq \prod_{i<m} r_i \cdot B$ *for every* c *and every* x *in the support, and*

$$\sum_c \sum_{\mathsf{x}} \Psi(\mathsf{x})\, \beta_c\Big(\bigotimes_{i<m} \Phi_{\mathsf{x},i}\Big) = \Big(\sum_{\mathsf{x}} \Psi(\mathsf{x})\, \mathrm{C}_{D,\vartheta}(\Phi_{\mathsf{x}})_m \varphi\Big)(g).$$

Proof. Input I8(iii) with the properties $\mathcal{C}_i(g, \xi)$: $\mathrm{N}_i(g, \xi) \leq \prod_{i'<i} r_{i'} \cdot B$. They propagate by the hypothesis on the kernels and $r_i \geq 0$. □

LEAN `Data.exists_chain_eq_sum`

Proposition 5.5 (gains of the lifts add along the chain)**.** *In Setting 5.1, for every natural number* i *let* t_i *be a* $\mathbb{C}$*-linear endomorphism of* $\mathcal{W}_i(D)$ *such that* $\omega_{D,\vartheta,i}(a, a')\, t_i\, \mathrm{td}_D(\mathsf{x}, i) = t_i\, \omega_{D,\vartheta,i}(a, a')\, \mathrm{td}_D(\mathsf{x}, i)$ *for every* x *in the support of* Ψ*, every* $a \in K_i^{\mathrm{col}}(D)$ *and every* $a' \in K_{i+1}^{\mathrm{col}}(D)$*; let* $d_i \in G_{X_i(D)}$ *be points and* r_i *real numbers such that, for every* x *in the support of* Ψ *and every* $i < m$*,*

$$t_i\, \mathrm{td}_D(\mathsf{x}, i) \in \mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(d_i, d_{i+1}; p^{r_i}).$$

Let $\varphi \in \mathrm{Col}(D)$ *have* j*-gauge at most* 1 *at* d_0*. Then the form* $\sum_{\mathsf{x}} \Psi(\mathsf{x}) \cdot \mathrm{C}_{D,\vartheta}((t_i \mathrm{td}_D(\mathsf{x}, i))_i)_m \varphi$ *has* j*-gauge at most* $p^{\sum_{i<m} r_i}$ *at* d_m*.*

Proof. The combination of the data $t_i \mathrm{td}_D(\mathsf{x}, i)$ is jointly invariant: it is the image of the tensor of (G2) under $\bigotimes_i t_i$, which commutes with the action of the levels on the data in the support. Apply Lemma 5.4 with $\mathrm{N}_i(g, \xi) = \mathrm{gauge}_j^{\varkappa_D, \mathrm{last}_D(i,\cdot)}(gd_i; \xi)$, the numbers p^{r_i} and $B = 1$. The value of the form at a point is a sum of terms $\Psi(\mathsf{x})\beta_c(\dots)$; the gauge is ultrametric, the gauge of each $\beta_c(\dots)$ is at most $p^{\sum r_i}$, and $|j(\Psi(\mathsf{x}))|_p \le 1$ by (G1), since p is prime to $\mathrm{nrm}(\vartheta)$. □

LEAN `Data.IsGoodDatum.gaugeLe_chain`

6 Served primes, induced primes and marked sets

Lemma 6.1 (orders and losses)**.** *In Setting 2.1:*

(a) For every prime number p, $\mathfrak{r}(D, p) \le \log x_1$.

(b) If p is a prime number that is served for D, then m divides the order of the place $[-p]_D$ in the group $\mathrm{Pl}(D)$.

(c) For every natural number p, $f(D)\,(\log b)^2 \cdot a(D)/p \;\le\; \mathrm{loss}(D, p)$.

(d) For natural numbers p and e with e odd and every $\tau \in \mathrm{tops}(D)$: the place $[-p^e]_D \cdot \tau$ lies in $\mathrm{tops}(D)$ if and only if $o_0(D, p)$ divides e.

Proof. (a) $m \le 2^{\mu(D)} \le p^{\mu(D)}$, so $\mathfrak{r}(D, p) \le \mu(D)$, and $\mu(D) \le \log x_1$ by size. (c) The last factor of $\mathrm{loss}(D, p)$ is $m \ge 1$ or 1. (d) Since e is odd, $[-p^e]_D = [-p]_D^e$; the tops are the places of class 1 modulo N_0, so the product is a top exactly when the class of $[-p]_D$ has order dividing e. (b) The data have $m = 2^{c+1}$ and $\mu(D) = 22(c+1)$ for a natural number c, and $2^{\mu(D)+1}$ divides $N_1(D)$. Let $n \ge 1$ be the order of $[-p]_D$. The class of this place modulo $2^{\mu(D)+1}$ is that of $-p$ (unit 152; p is prime to N_0 because $\chi_{K(P)}(p) \ne 1$), so $(-p)^n \equiv 1$ modulo $2^{\mu(D)+1}$. By lifting the exponent at 2 (background library), $2^{\mu(D)}$ divides $(-p-1)n$ or $(-p+1)n$. Since p is not short, 2^{c+1} divides neither $p+1$ nor $p-1$; so $2^{\mu(D)-c}$ divides n, and $\mu(D) - c \ge c+1$. □

Lemma 6.2 (induced primes)**.** *In Settings 2.1 and 2.2, let $\tau, \tau' \in \mathrm{Pl}(D)$.*

(a) $p \in \mathfrak{l}_j(\tau)$.

(b) $\mathfrak{l}_j(\tau \cdot \tau') = \tau' \cdot \mathfrak{l}_j(\tau)$, where a place acts on the primes through the automorphism of $E(D)$ over $K(P)$ that it names.

(c) If $\chi_{K(P)}(p) = -1$ and e is an odd natural number, then $\mathfrak{l}_j([-p^e]_D \cdot \tau) = \overline{\mathfrak{l}_j(\tau)}$.

(d) If $\chi_{K(P)}(p) = -1$, then $\mathfrak{l}_j(\tau)$ is equal to $\mathfrak{l}_j(\tau')$ or to $\overline{\mathfrak{l}_j(\tau')}$ if and only if $\tau = [-p]_D^n \cdot \tau'$ for some natural number n.

Proof. (a) $|j(p)|_p < 1$. (b) The embedding at $\tau\tau'$ is the embedding at τ composed with the automorphism named by τ' (unit 152). (c), (d) For p inert in $K(P)$ and prime to $N_1(D)\,d$, the decomposition of p in $E(D)$ is described in the note on the CM field: a place v maps a prime above p to itself or to its conjugate exactly when v is a power of $[-p]_D$, to the conjugate for odd powers. With (b) this gives both claims. □

Lemma 6.3 (a full mark exists at a served prime)**.** *In Settings 2.1 and 2.2, assume that $p < x_1$ and that p is served for D. Then there is a finite set $\mathcal{L}$ of finite places of $E(D)$ that is a full mark.*

Proof. Fix a well-ordering of the finite places and let $\mathcal{L}$ be the set of the primes $\mathfrak{l} = \mathfrak{l}_j(\tau)$, $\tau \in \mathrm{tops}(D)$, that are smaller than their conjugate. Then (M1) and (M3) hold by construction, and (M2), (M4) by hypothesis, a served prime being inert. For the covering, let τ be a top. By Lemma 6.1(d) the place $\tau' = [-p]_D^{o_0(D,p)} \cdot \tau$ is a top, and it induces $\overline{\mathfrak{l}_j(\tau)}$ by Lemma 6.2(c), $o_0(D,p)$ being odd. Moreover $\mathfrak{l}_j(\tau) \neq \overline{\mathfrak{l}_j(\tau)}$: by Lemma 6.1(b) the order of $[-p]_D$ is even, so its odd powers do not fix a prime above p. Hence one of the two primes is the smaller and lies in $\mathcal{L}$. □

LEAN Data.exists_isMarked

Setting 6.4 (a marked set)**.** Settings 2.1 and 2.2 hold, and $\mathcal{L}$ is a finite set of finite places of $E(D)$ that is marked for D, p and j (Input I5).

Lemma 6.5 (marked sets)**.** *In Setting 6.4:*

(a) $\#\mathcal{L} \leq f(D)$.

(b) *p does not divide $g(D)$, $p \neq N(D)$, and p does not divide $g(D)\,N(D)$.*

(c) *For every $\mathfrak{l} \in \mathcal{L}$: $p \in \mathfrak{l}$; p is a uniformiser at $\mathfrak{l}$; $\bar{\mathfrak{l}} \neq \mathfrak{l}$; and $K_{X_0(D)}[\mathfrak{l}] \subseteq K_0^{\mathrm{col}}(D)$.*

Proof. (a) $\mathcal{L}$ lies in the image of $\tau \mapsto \mathfrak{l}_j(\tau)$. (b) $p < x_1$, and the primes g_0, g_1, $N(D)$ are larger than x_1 by size. (c) The first claim is Lemma 6.2(a). p is unramified in $E(D)$, being prime to $N_1(D)\,d$ (an inert or ramified p does not divide $N_1(D)$, and if $\mathcal{L} \neq \emptyset$ then p is served, so $p \neq d$). The third claim is (M1). For the last, by (b) the element $\overline{\pi_g(D)}\pi_N(D)$ is a unit at $\mathfrak{l}$ and $\bar{\mathfrak{l}}$, so $K_{X_0(D)}[\mathfrak{l}]$ lies in the principal level of this element, and Lemma 3.2(a) applies. □

LEAN Data.IsMarked.card_le · Data.IsMarked.not_dvd_gProd_mul_N · Data.IsMarked.p_mem · Data.IsMarked.valuation_p · Data.IsMarked.star_ne · Data.IsMarked.maxCompactAt_le_columnLevel

Lemma 6.6 (marked primes avoid the thick places; a balance)**.** *In Setting 6.4:*

(a) *If $\tau \in \mathrm{Pl}(D)$ is such that $\mathfrak{l}_j(\tau) \in \mathcal{L}$ or $\overline{\mathfrak{l}_j(\tau)} \in \mathcal{L}$, then $\tau \notin \mathrm{thick}(D)$.*

(b) *For every natural number i and every real function G of a natural number and a finite place,*

$$\sum_{\tau \in \mathrm{Pl}(D)} \Big([\mathfrak{l}_j(\tau) \in \mathcal{L}]\, G\big(\mathrm{wt}_D(i,\tau), \mathfrak{l}_j(\tau)\big) - [\overline{\mathfrak{l}_j(\tau)} \in \mathcal{L}]\, G\big(\mathrm{wt}_D(i,\tau), \overline{\mathfrak{l}_j(\tau)}\big) \Big) = 0.$$

Proof. (a) $\mathcal{L}$ is not empty, so p is served: $\chi_{K(P)}(p) = -1$ and $o_0(D,p)$ is odd. By (M3) and Lemma 6.2(d), $\tau = [-p]_D^n \cdot \tau_0$ for a top τ_0 and some n, so the class of τ modulo N_0 is that of $(-p)^n$. A thick place has class -1 modulo N_0 (a condition of the data). If τ were thick, raising $(-p)^n \equiv -1$ to the odd power $o_0(D,p)$ would give $1 \equiv -1$ modulo N_0. (b) If $\mathcal{L}$ is empty both sums vanish. Otherwise p is inert; substitute $\tau \mapsto [-p]_D \cdot \tau$ in the second sum. By Lemma 6.2(c) the prime induced by the new place is $\overline{\mathfrak{l}_j(\tau)}$, so the condition becomes $\mathfrak{l}_j(\tau) \in \mathcal{L}$ and the place argument of G becomes $\mathfrak{l}_j(\tau)$; and the weight is unchanged, because by (a) neither τ nor $[-p]_D \cdot \tau$ is thick, and $\mathrm{wt}_D(i, \cdot\,)$ takes one value on the places that are not thick. □

7 The jet exponent

Lemma 7.1 (collisions). *In Setting 2.1, let Ξ be a finite subset of $\mathrm{Pl}(D)$.*

(a) Let p and e be natural numbers and $\tau \in \mathrm{Pl}(D)$. If (τ, e) is a collision of p outside Ξ for D, then $p \neq d$, e is odd, and $o_0(D,p)$ divides e.

(b) Let p be a prime number and o a natural number such that $o \le e$ for every collision (τ, e) of p outside Ξ for D. Then $\mathrm{coll}(D,p,\Xi) \le 2\, f(D)\, a(D)/p^o$.

(c) Let p be a prime number that is small and not split for D and is not served for D. Then $m \cdot \mathrm{coll}(D,p,\emptyset) \le \mathrm{loss}(D,p)$.

(d) In Setting 2.2, if $\mathcal{L}$ is a full mark, then $\mathrm{coll}(D,p,\Xi_j(\mathcal{L})) = 0$.

Proof. (a) Both τ and $[-p^e]_D \cdot \tau$ are tops, so they have the same class modulo N_0; by a lemma of unit 150 this excludes $p = d$ (no power of d is $\equiv -1$ modulo N_0). Then e is odd because (e,p) is live, and Lemma 6.1(d) applies. (b) For each τ the terms are $a(D)/p^e$ with $e \ge o$; they are bounded by the geometric series $\sum_{n\ge 0}(a(D)/p^o)2^{-n} = 2a(D)/p^o$, since $p \ge 2$; sum over the $f(D)$ places. (c) By $(\log b)^2 \ge 2$, $\mathrm{loss}(D,p) \ge 2f(D)(a(D)/p)\cdot(m \text{ or } 1)$. If p is short, use (b) with $o = 1$. If not, every collision has $e \ge \mathfrak{r}(D,p)+1$: by (a), e is odd, $o_0(D,p)$ divides e, hence $o_0(D,p)$ is odd, and $\chi_{K(P)}(p) = -1$; if $o_0(D,p) \le e \le \mathfrak{r}(D,p)$, then p would be served. So $\mathrm{coll}(D,p,\emptyset) \le 2f(D)a(D)/p^{\mathfrak{r}(D,p)+1}$ by (b), and $m \le p^{\mathfrak{r}(D,p)}$. (d) Suppose (τ,e) is a collision outside $\Xi_j(\mathcal{L})$. Then $\mathcal{L}$ is not empty, since it covers the top τ; so p is inert, e is odd by (a), and $[-p^e]_D \cdot \tau$ induces $\overline{\mathfrak{l}_j(\tau)}$ (Lemma 6.2(c)). As $\mathcal{L}$ covers τ, one of τ, $[-p^e]_D \cdot \tau$ lies in $\Xi_j(\mathcal{L})$, a contradiction. □

LEAN Data.IsCollision.ne_and_odd_and_dvd · Data.collisionSum_le · Data.mul_collisionSum_le_loss · Data.IsFullMark.collisionSum_evenPlaces_eq_zero · unit 150: Data.ne_d_of_placeClass_eq

Lemma 7.2 (low columns and low boxes). *In Setting 2.1, let $i < m$ be a natural number and $\tau \in \mathrm{Pl}(D)$. Then*

$$k(D)\cdot w_D(\tau) \le \mathrm{lb}_D(i,\tau) \le k(D)\cdot w_D(\tau) + x^{60} \qquad \text{and} \qquad \mathrm{lc}_D(i,\tau) \le w_D(\tau) + x^{60}.$$

Proof. The term $h = k(D)$ of $\mathrm{lb}_D(i,\tau)$ is $k(D)(\mathrm{wt}_D(1,\tau) - \lfloor (k(D)+t(D)+1)/2 \rfloor) \ge k(D)\, w_D(\tau)$ (unit 152). For the upper bounds, each $\varkappa_D(\tau,h)$ with $h \neq 1$ is at most $[h = k(D)]\mathrm{wt}_D(1,\tau) + \mathrm{gap}(D)$ (unit 150), $\mathrm{wt}_D(1,\tau)$ exceeds $w_D(\tau)$ by a small amount (unit 152), and the sums of the remaining terms over $h < n_{i+1}(D) \le n_m(D)$ are at most x^{60} by size. □

Proposition 7.3 (the jet exponent is at least the gain of one lift, up to collisions). *In Setting 2.1, let p be a prime number that is small and not split for D, $i < m$ a natural number and Ξ a finite subset of $\mathrm{Pl}(D)$. Then*

$$\frac{\mathrm{gain}(D,p)}{m} - \mathrm{coll}(D,p,\Xi) + \frac{1-\chi_{K(P)}(p)}{2}\cdot \#\big(\mathrm{tops}(D)\cap\Xi\big)\cdot\frac{a(D)}{x_1} - f(D)\,(\log b)^2\,\frac{a(D)}{p}\cdot\frac{1}{m} \;\le\; \mathrm{je}_D(p,i,\Xi).$$

Proof. Write $c = (1-\chi_{K(P)}(p))/2 \in \{\frac{1}{2},1\}$, $n' = n_{i+1}(D)$, $L = \mathrm{boxes}(\varkappa_D, n')$, $l = \lfloor \log_p L \rfloor$, $\eta = a(D)/(pm)$, and $\tau_e = [-p^e]_D \cdot \tau$. Since $n' > 1$, the columns of height one contribute $a(D)$ at each top, so $L = \sum_\tau (\varkappa_D(\tau,1) + \mathrm{lb}_D(i,\tau))$, and by (1)

$$\Big(\frac{1}{p-1} - \varrho_d(p)\Big) L = c \sum_\tau \sum_{e:\ (e,p)\ \mathrm{live}} \frac{\varkappa_D(\tau,1) + \mathrm{lb}_D(i,\tau)}{p^e}.$$

By the definitions of Input I6, $\mathrm{gain}(D,p)/m = c\sum_\tau \sum_{e\ \mathrm{live}} ([\tau \in \mathrm{tops}(D)](a(D)/p^e - w_D(\tau_e))_+ + k(D)(w_D(\tau)/p^e - w_D(\tau_e))_+)$. For a place τ and a natural number e let lv_e be 1 if (e,p) is live and 0 otherwise, and $\mathrm{cl}_{\tau,e}$ be 1 if (τ,e) is a collision of p outside Ξ for D and 0 otherwise. The claim follows by summation over τ and e from the following inequality, for each τ and e:

$$\begin{aligned}[e \le l]\Big([e \text{ odd or } p = d]\ \mathrm{cc}_p(\varkappa_D, n'; \Xi; \tau, \tau_e; e) - 4\eta\Big) + [e=1]\,[\tau \in \mathrm{tops}(D) \cap \Xi]\,\frac{a(D)}{x_1} \\ + \mathrm{lv}_e\Big([\tau \in \mathrm{tops}(D)](\tfrac{a(D)}{p^e} - w_D(\tau_e))_+ + k(D)(\tfrac{w_D(\tau)}{p^e} - w_D(\tau_e))_+\Big) \\ \le\ \mathrm{lv}_e\,\frac{\varkappa_D(\tau,1) + \mathrm{lb}_D(i,\tau)}{p^e} + \mathrm{cl}_{\tau,e}\,\frac{a(D)}{p^e}. \quad (2)\end{aligned}$$

Indeed, multiply (2) by c and sum: the right side gives $(1/(p-1) - \varrho_d(p))L + c\,\mathrm{coll}(D,p,\Xi)$, the left side gives $c\sum \mathrm{cc}_p(\varkappa_D, n'; \Xi; \tau, \tau_e; e) - 4c\,\eta\, f(D)(l+1) + \mathrm{gain}(D,p)/m + c\#(\mathrm{tops}(D) \cap \Xi)a(D)/x_1$, and therefore

$$\begin{aligned}\mathrm{je}_D(p,i,\Xi)\ \ge\ \frac{\mathrm{gain}(D,p)}{m} + c\,\#(\mathrm{tops}(D)\cap\Xi)\frac{a(D)}{x_1} \\ - c\,\mathrm{coll}(D,p,\Xi) - (4c\,\eta + {n'}^3) f(D)(l+1).\end{aligned}$$

Now $c \le 1$, the collision sum is non-negative, ${n'}^3 \le x^{60} \le \eta$ by size (here $p < x_1$ is used), and $5(l+1) \le (\log b)^2$ by size, because $l \le \log L/\log 2$ and $L = \#\mathrm{tops}(D)\cdot a(D) + \sum_\tau \mathrm{lb}_D(i,\tau)$ is bounded through Lemma 7.2 (the formal text compares each $\mathrm{lb}_D(i,\tau)$ with the number $g(D)$ of the data, a device of its tactic for size comparisons, not a step of the argument). This gives the proposition.

Proof of (2). The facts used are: $a(D)/x_1 \le w_D(\tau') \le a(D)/x$ for every place τ', with $w_D(\tau') = a(D)/x_1$ when τ' is not thick; Lemma 7.2; and the sizes $x^{60} \le \eta$, $a(D)/(xp) + x^{60}/p \le \eta$. Put $\tau' = \tau_e$ and recall that in the coupling count $\mathrm{one}_\tau = [\tau \in \mathrm{tops}(D) \setminus \Xi]\,a(D)$, the count of the other columns is $\mathrm{lc}_D(i,\tau)$ and their boxes are $\mathrm{lb}_D(i,\tau)$.

The pair (e,p) is live and $e \le l$. Three bounds add up to (2). (1) $\mathrm{lc}_D(i,\tau)/p^e \le \eta$. (2) $\min(\mathrm{lb}_D(i,\tau)/p^e, \mathrm{lb}_D(i,\tau')) + k(D)(w_D(\tau)/p^e - w_D(\tau'))_+ \le \mathrm{lb}_D(i,\tau)/p^e + x^{60}$: if the positive part vanishes this is clear; otherwise bound the minimum by $\mathrm{lb}_D(i,\tau') \le k(D)w_D(\tau') + x^{60}$ and use $k(D)w_D(\tau) \le \mathrm{lb}_D(i,\tau)$. (3) $\min(\mathrm{one}_\tau/p^e, \mathrm{lc}_D(i,\tau') + \mathrm{one}_{\tau'}) + [\tau \in \mathrm{tops}(D)](a(D)/p^e - w_D(\tau'))_+ + [e=1][\tau \in \mathrm{tops}(D)\cap\Xi]a(D)/x_1$ is at most $\varkappa_D(\tau,1)/p^e + x^{60}$ plus $a(D)/p^e$ if (τ,e) is a collision. If τ is not a top, the left side is 0. If $\tau \in \mathrm{tops}(D) \cap \Xi$, then $\mathrm{one}_\tau = 0$, so the minimum is 0. For $e = 1$ the two other terms satisfy $(a(D)/p - w_D(\tau'))_+ + a(D)/x_1 \le a(D)/p$: if the positive part vanishes, because $a(D)/x_1 \le a(D)/p$ ($p < x_1$); if not, because $w_D(\tau') \ge a(D)/x_1$. For $e \ne 1$ the last term is absent and $(a(D)/p^e - w_D(\tau'))_+ \le a(D)/p^e$. In both cases the left side is at most $\varkappa_D(\tau,1)/p^e$. If $\tau \in \mathrm{tops}(D) \setminus \Xi$ and (τ,e) is a collision,

both terms are at most $a(D)/p^e$. If $\tau \in \mathrm{tops}(D) \setminus \Xi$ and it is not a collision, then $\mathrm{one}_{\tau'} = 0$, and either the positive part vanishes, or the minimum is at most $\mathrm{lc}_D(i,\tau') \le w_D(\tau') + x^{60}$ and the sum is at most $a(D)/p^e + x^{60}$. Altogether the loss is at most $\eta + 2x^{60} \le 4\eta$.

The pair (e,p) is live and $e > l$. Only the second and third groups of the left side occur, and $k(D)(w_D(\tau)/p^e - w_D(\tau'))_+ \le \mathrm{lb}_D(i,\tau)/p^e$, $[\tau \in \mathrm{tops}(D)]((a(D)/p^e - w_D(\tau'))_+ + [e=1][\tau \in \Xi]a(D)/x_1) \le \varkappa_D(\tau,1)/p^e$, as before.

The pair is not live. Then $e = 0$, or e is even and $p \ne d$, and the right side is 0. For $e \ge 2$ the left side is -4η or 0. For $e = 0$ and $p \ne d$ likewise. For $e = 0$ and $p = d$ the place $\tau' = [-1]_D \cdot \tau$ has the class of τ times -1 modulo N_0, so at most one of τ, τ' is a top and at most one is thick; hence the first minimum is at most $\mathrm{lc}_D(i,\tau')$ or 0, the second is at most $\mathrm{lb}_D(i,\cdot)$ at a place that is not thick, which is at most $k(D)a(D)/x_1 + x^{60}$, and with $p = d$ these three terms are at most η each by size. So the coupling count is at most 3η. □

Lemma 7.4 (the cost of the marks is within the loss)**.** *In Setting 6.4, let $i < m$ be a natural number. Then*

$$\#\mathcal{L} \cdot \Delta(D,p) + \mathfrak{r}(D,p) \sum_{\tau \in \Xi_j(\mathcal{L})} \mathrm{lc}_D(i,\tau) \;\le\; \frac{\mathrm{loss}(D,p)}{m} + \#(\mathrm{tops}(D) \cap \Xi_j(\mathcal{L})) \cdot \frac{a(D)}{x_1}.$$

Proof. It suffices to show $\mathfrak{r}(D,p)\,\mathrm{lc}_D(i,\tau) \le a(D)/(pm) + [\tau \in \mathrm{tops}(D)]\,a(D)/x_1$ for $\tau \in \Xi_j(\mathcal{L})$: then the left side is at most $f(D)\mathfrak{r}(D,p)f(D)(n_m(D) + \mathfrak{r}(D,p)) + f(D)a(D)/(pm) + \#(\mathrm{tops}(D) \cap \Xi_j(\mathcal{L}))a(D)/x_1$ by Lemma 6.5(a), and the first two terms are at most $f(D)(\log b)^2 a(D)/(pm) \le \mathrm{loss}(D,p)/m$ by size and Lemma 6.1(c). Let $\tau \in \Xi_j(\mathcal{L})$. By Lemma 6.6(a), τ is not thick, so $\mathrm{lc}_D(i,\tau) \le a(D)/x_1 + x^{60}$ by Lemma 7.2. If $p \le m$, then $\mathfrak{r}(D,p)(a(D)/x_1 + x^{60}) \le a(D)/(pm)$ by size, using Lemma 6.1(a). If $m \le p$, then $\mathfrak{r}(D,p) = 1$; p is served because $\mathcal{L}$ is not empty, so $o_0(D,p) \le 1$, that is, $-p \equiv 1$ modulo N_0; by (M3) and Lemma 6.2(d), τ is a power of $[-p]_D$ times a top, hence a top; and $x^{60} \le a(D)/(pm)$ by size. □

LEAN Data.IsMarked.sum_lowColumns_le

8 Hecke operators through the chain

Input I9 (divisibility of jets; unit 150, and the Hecke transfer of the background library). (i) (*Gauges from a jet bound.*) In Settings 2.1 and 2.2, let ϑ be a twist, i a natural number, δ an integer of $K(P)$ and $\Phi' \in \mathrm{Std}_{\delta}(D,i)$. Let $y, y' \in G_{X_{i+1}(D)}$ be integral and invertible at all primes above p, and let y'' be a point of $G_{X_{i+1}(D)}$ whose image under $x \mapsto j(\iota_\tau(\overline{x}))$ is, for every τ, a diagonal matrix $\mathrm{diag}(u_\tau)$. Let B be a real number such that for every $\Phi \in \mathrm{Std}_{\delta}(D,i)$ and all Weyl indices c', c the entry (c',c) of the jet matrix of Φ at the scale of the lift kernel, multiplied by $\prod_\tau (\prod_a |u_\tau(a)|_p)^{\mathrm{last}_D(i+1,\tau)}$ and by the product of $|u_\tau(a)|_p$ over the entries a of the tableau c' at τ, has p-adic absolute value at most B. Then $\omega_{D,\vartheta,i}(1, yy''y')\Phi' \in \mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(1,1;B)$.
(ii) (*Jets of standard data are governed by theta products.*) For $\Phi \in \mathrm{Std}_{\delta}(D,i)$, a complex number c and a $\mathbb{C}$-linear form lf on power series: if $|j(\mathrm{lf}(\Theta))|_p \le r$ for every power series Θ whose image under j lies in the set $\mathrm{ThProd}_{P,\mu(D)}(\delta, |j(c\,s_1)|_p; X_{i+1}(D) \times X_i(D))$ of theta products of the CM curve (s_1 the period factor), then $|j(\mathrm{lf}(T))|_p \le r$ for the Taylor series T of the theta function of Φ at the scale $c \cdot \mathrm{per}(P, \mu(D))$. If p does not divide $N_1(D)$, then $|j(s_1)|_p = 1$.
(iii) (*Normal form and divisibility of Schur jets.*) Let $\chi_{K(P)}(p) \neq 1$. Every theta product Θ in $\mathrm{ThProd}_{P,\mu(D)}(1, r; I)$ with $r \le 1$ is *integral on the null cone* in every degree, for the maps $\tau \mapsto [-p^e]_D \cdot \tau$, the exponents $e \le \lfloor \log_p L \rfloor$ with e odd or $p = d$, and elements ϖ of $\mathbb{C}_p$ and ϖ_0 of $\mathfrak{o}_p$ with $|\varpi|_p = p^{-\varrho_d(p)}$ and $|\varpi_0|_p = p^{(\chi_{K(P)}(p)-1)/2}$. For a series Θ that is integral on the null cone up to the degree $L = \mathrm{boxes}(\varkappa, n')$, a finite set Ξ of places and a family of *charges*, natural numbers $\mathrm{ch}(\tau, h, a)$ attached to a place, a height and an index, such that for every exponent e as above, every place τ, height h and index a

$$\tau \in \Xi \ \text{ or } \ (h = 1 \text{ and } [-p^e]_D \cdot \tau \in \Xi) \\ \Longrightarrow \quad \mathrm{ch}(\tau, 1, a) \neq 0 \ \text{ or } \ \mathrm{ch}([-p^e]_D \cdot \tau, h, a) \neq 0, \quad (3)$$

the entry (c', c) of the matrix of jets of Θ along the Schur matrix of $\varkappa$ has absolute value at most p to the power: the total charge of the boxes of the tableau c', minus

$$(\tfrac{1}{p-1} - \varrho_d(p))L - \tfrac{1-\chi_{K(P)}(p)}{2} \sum_{e,\tau} \mathrm{cc}_p(\varkappa, n'; \Xi; \tau, [-p^e]_D \cdot \tau; e) \\ - \#\,\mathrm{Pl}(D)\, n'^3 (\lfloor \log_p L \rfloor + 1).$$

For $\varkappa = \varkappa_D$ and $n' = n_{i+1}(D)$ the subtracted number is $\mathrm{je}_D(p, i, \Xi)$.

Input I9, continued. (iv) (*Hecke transfer.*) Let w be a finite place with $\overline{w} \neq w$; consider a theta lift from rank n to rank $n+k'$ whose two characters are unramified at w and whose datum is a vacuum at w and $\overline{w}$. Then the lift of a form φ fixed by the group at w is fixed by the group at w, and the Hecke polynomials $\mathrm{H}_w(X) = \sum_{n''} (-X)^{n''} \mathrm{q}_w^{n''(n''-1)/2} T_{w,n''}$ satisfy

$$\mathrm{H}_w(X)\,\mathrm{lift}(\varphi) = \prod_{l<k'} (1 - \mathrm{q}_w^{l}\,\alpha X) \cdot \mathrm{lift}\big(\mathrm{H}_w(\mathrm{q}_w^{k'}\,\alpha\alpha'^{-1} X)\varphi\big),$$

where α and α' are the values at a uniformiser of w of the Hecke characters of the two characters, normalised by $\mathrm{q}_w^{n/2}$ and $\mathrm{q}_w^{(n+k')/2}$.

(b) for every form $\varphi \in \mathrm{St}_0(D)$ *that is fixed by the group* $K_{X_0(D)}[\mathfrak{l}]$*, with* $C = \mathrm{C}_{D,\vartheta}(\mathrm{td}_D(\mathsf{x},\,\cdot\,))_{i+1}$*,*

$$\sum_{n \le \mathfrak{r}(D,p)} c_n\, T_{\mathfrak{l},n}(C\varphi) = p^{\Delta(D,p)} \cdot C(T_{\mathfrak{l},\mathfrak{r}(D,p)}\varphi).$$

Proof. By Lemma 6.5, p does not divide $g(D)N(D)$ and $p \in \mathfrak{l}$; by hypothesis p is prime to $\mathrm{nrm}(\vartheta)$. So $\mathfrak{l}$ and $\overline{\mathfrak{l}}$ are not chosen, do not divide $\pi_N(D)$ and do not lie in $Q(\vartheta)$ or its conjugate, and the characters of all the lifts are unramified at $\mathfrak{l}$. Since $\mathcal{L}$ is not empty, p is served; by Lemma 6.1(b) the order of $[-p]_D$ is even, say $2o'$, and the residue field of $\mathfrak{l}$ has $\mathrm{q} = p^{2o'}$ elements (the decomposition of an inert prime, unit 152). For x in the support, Lemma 5.2 shows that every datum $\mathrm{td}_D(\mathsf{x},i')$ is a vacuum at $\mathfrak{l}$ and $\overline{\mathfrak{l}}$; an element a as in (a) then acts on it through a value of an unramified character, which is 1. This is (a).

For (b), Input I9(iv) applies to each of the lifts of C, with $k' = t(D)+1$. Put $y_e = p^{o'(n_{i+1}(D) - n_e(D))}$. By induction on the number e of lifts, for the chain C_e of the first e lifts and all complex U,

$$\mathrm{H}_{\mathfrak{l}}(-U y_e)\, C_e\varphi = \prod_{e'<e} \prod_{l \le t(D)} (1 + U\,\mathrm{q}^{l}\,p^{o' n_i(D)}\,\alpha_{e'}) \cdot C_e(\mathrm{H}_{\mathfrak{l}}(-U y_0)\varphi),$$

where $\alpha_{e'}$ is the value at the uniformiser of the character of the lift e'. (Two facts enter the induction step. In Input I9(iv) for the lift e' the two characters take the same value $\alpha_{e'}$ at the uniformiser, so that $\alpha\alpha'^{-1} = \mathrm{q}^{-k'/2}$ and the variable is rescaled by $\mathrm{q}^{k'/2} = p^{o'(t(D)+1)}$, which turns $y_{e'+1}$ into $y_{e'}$. And the normalising factor of the lift e' times $y_{e'+1}$ is $\mathrm{q}^{n_{e'}(D)/2}\, y_{e'+1} = p^{o'(n_{e'}(D) + n_{i+1}(D) - n_{e'+1}(D))} = p^{o' n_i(D)}$, the

same for every e'.) These values are integral at j: the character of the lift e' has weights $-\mathrm{wt}_D(e',\tau)$, so $|j(\alpha_{e'})|_p$ is a product over τ of powers of p whose exponents are $\mathrm{wt}_D(e',\tau)$ at the places inducing $\mathfrak{l}$ and $-\mathrm{wt}_D(e',\tau)$ at those inducing $\bar{\mathfrak{l}}$, up to a common sign, and by Lemma 6.6(b), with $G(c,w) = -c\,[w = \mathfrak{l}]$, the exponents cancel. Taking $e = i+1$, the product is a polynomial $\Pi(U)$ with coefficients in O_j and constant term 1. Comparing the coefficients of $U^{\mathfrak{r}(D,p)}$ after multiplication by the inverse power series $\Pi(U)^{-1}$, which again has coefficients in O_j, expresses $C(T_{\mathfrak{l},\mathfrak{r}(D,p)}\varphi)$, times a power of p coming from y_0 and from $\mathrm{q}^{\mathfrak{r}(D,p)(\mathfrak{r}(D,p)-1)/2}$, as a combination of the $T_{\mathfrak{l},n}(C\varphi)$, $n \le \mathfrak{r}(D,p)$, with coefficients that are elements of O_j times powers of p; the identity needs $\mathfrak{r}(D,p) \le k(D)$, which holds by size. Multiplying by $p^{\Delta(D,p)}$ and dividing by the power of p on the left gives the numbers c_n. For $i < m$ they are integral: the exponents of p that are divided out are at most $2o'\,\mathfrak{r}(D,p)\,(n_m(D) + \mathfrak{r}(D,p))$, and $2o' \le f(D)$ because the order of an element of $\mathrm{Pl}(D)$ is at most $f(D)$; this is the definition of $\Delta(D,p)$. □

LEAN `Data.IsGoodDatum.exists_hecke_transfer` · unit 152: `Parameters.q_eq_inert` · unit 141: `Data.hasWeight_liftChar`

Proposition 8.2 (Hecke translates of the data raise gauges by a controlled amount)**.** *In Settings 5.1 and 6.4, let* x *be in the support of* Ψ*,* i *a natural number, and* $g = (g_{\mathfrak{l}})_{\mathfrak{l}\in\mathcal{L}}$ *a family with* $g_{\mathfrak{l}} \in \mathrm{GL}_{X_{i+1}(D)}(E(D)_{\mathfrak{l}})$ *such that every* $g_{\mathfrak{l}}$ *lies in the basic double coset of some index* $n \le \mathfrak{r}(D,p)$ *at* $\mathfrak{l}$*. Then*

$$\omega_{D,\vartheta,i}(1,\mathrm{at}(g))\,\mathrm{td}_D(\mathsf{x},i) \;\in\; \mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(1,1;p^{\sum_{\mathfrak{l}\in\mathcal{L}} A_D(\mathfrak{l})+\mathrm{ll}_{D,p}(\mathcal{L},i)}).$$

Proof. By Lemma 6.5, p is a uniformiser at each $\mathfrak{l} \in \mathcal{L}$, so $g_{\mathfrak{l}}$ is the product of an integral invertible matrix $y_{\mathfrak{l}}$, the diagonal matrix with entries p at the indices of a set $J_{\mathfrak{l}}$ and 1 elsewhere, and an integral invertible matrix $y'_{\mathfrak{l}}$; the set $J_{\mathfrak{l}}$ has at most $\mathfrak{r}(D,p)$ elements. Thus $\mathrm{at}(g) = y\,y''\,y'$ with $y, y' \in K_{X_{i+1}(D)}$ and a point y'' whose component at $\mathfrak{l} \in \mathcal{L}$ is the diagonal matrix with entries p on $J_{\mathfrak{l}}$ and 1 elsewhere, whose component at $\bar{\mathfrak{l}}$ is the inverse of that matrix (unitarity forces it), and which is 1 at the other places. The image of y'' at a place τ is taken under $x \mapsto j(\iota_\tau(\overline{x}))$ (Input I1). The prime of this embedding is the conjugate of the induced prime $\mathfrak{l}_j(\tau)$, so the image reads the component of y'' at $\overline{\mathfrak{l}_j(\tau)}$: it is the diagonal matrix with entries $u_\tau(a) = p^{\epsilon_\tau(a)}$,

$$\epsilon_\tau(a) = [\overline{\mathfrak{l}_j(\tau)} \in \mathcal{L},\, a \in J_{\overline{\mathfrak{l}_j(\tau)}}] - [\mathfrak{l}_j(\tau) \in \mathcal{L},\, a \in J_{\mathfrak{l}_j(\tau)}].$$

So $|u_\tau(a)|_p = p$ if $\mathfrak{l}_j(\tau) \in \mathcal{L}$ and $a \in J_{\mathfrak{l}_j(\tau)}$; $|u_\tau(a)|_p = p^{-1}$ if $\overline{\mathfrak{l}_j(\tau)} \in \mathcal{L}$ and $a \in J_{\overline{\mathfrak{l}_j(\tau)}}$; and $|u_\tau(a)|_p = 1$ otherwise (by (M1) the two conditions exclude each other). By Lemma 5.3 with $\delta = 1$ (recall $p \nmid g(D)$ and $p \ne N(D)$), the datum lies in $\mathrm{Std}_1(D,i)$, and Input I9(i) reduces the claim to a bound for the jets of all $\Phi \in \mathrm{Std}_1(D,i)$.

Let $\mathrm{ch}(\tau,h,a) = 1$ if ($\mathfrak{l}_j(\tau) \in \mathcal{L}$, $h = 1$ and $a \notin J_{\mathfrak{l}_j(\tau)}$) or ($\overline{\mathfrak{l}_j(\tau)} \in \mathcal{L}$ and $a \in J_{\overline{\mathfrak{l}_j(\tau)}}$), and 0 otherwise. Condition (3) holds for $\Xi = \Xi_j(\mathcal{L})$: if $\tau \in \Xi$ and $a \notin J_{\mathfrak{l}_j(\tau)}$, then $\mathrm{ch}(\tau,1,a) = 1$; if $\tau \in \Xi$ and $a \in J_{\mathfrak{l}_j(\tau)}$, then the place $[-p^e]_D \cdot \tau$ induces $\overline{\mathfrak{l}_j(\tau)}$ (Lemma 6.2(c); p is inert and e is odd), so its charge at a is 1; the case $h = 1$, $[-p^e]_D \cdot \tau \in \Xi$ is symmetric. By Input I9(ii) and (iii), applied with $c = \overline{\pi_g(D)}$, for which $|j(c\,s_1)|_p \le 1$ (indeed $|j(\overline{\pi_g(D)})|_p \le 1$ by Lemma 3.2(i), and $|j(s_1)|_p = 1$ by Input I9(ii), because p, which does not split in $K(P)$, does not divide $N_1(D)$), every

entry (c', c) of the jet matrix of $\Phi \in \mathrm{Std}_1(D, i)$ has absolute value at most p to the power (charges of c') $-\mathrm{je}_D(p, i, \Xi_j(\mathcal{L}))$.

It remains to count the exponent of p in the bound B of Input I9(i). The determinant factors contribute $\sum_\tau \mathrm{last}_D(i+1,\tau)\cdot(-\sum_a \epsilon_\tau(a))$, and $\mathrm{last}_D(i+1,\tau) = \lfloor n_i(D)/2\rfloor - \mathrm{wt}_D(i+1,\tau)$; by Lemma 6.6(b) with $G(c,w) = \#J_w\cdot(\lfloor n_i(D)/2\rfloor - c)$ this sum is 0. For a box of c' at τ with entry a, the factor $|u_\tau(a)|_p$ and the charge together contribute to the exponent: exactly 1 if $\mathfrak{l}_j(\tau)\in\mathcal{L}$ and the box lies in a column of height one (either $a \in J_{\mathfrak{l}_j(\tau)}$, $|u_\tau(a)|_p = p$ and the charge is 0, or $a \notin J_{\mathfrak{l}_j(\tau)}$, $|u_\tau(a)|_p = 1$ and the charge is 1); 1 if $\mathfrak{l}_j(\tau)\in\mathcal{L}$, the box lies in a higher column and $a \in J_{\mathfrak{l}_j(\tau)}$ ($|u_\tau(a)|_p = p$, charge 0); and 0 in the other cases (a charge 1 at a place inducing the conjugate of a marked prime comes with $|u_\tau(a)|_p = p^{-1}$, which cancels it). The entries of a column of a tableau are distinct, so a higher column at $\tau\in\Xi_j(\mathcal{L})$ contributes at most $\#J_{\mathfrak{l}_j(\tau)} \le \mathfrak{r}(D,p)$. Summing: the columns of height one give at most $\sum_{\tau\in\Xi_j(\mathcal{L})}\varkappa_D(\tau,1) = \sum_{\mathfrak{l}} A_D(\mathfrak{l})$, the others at most $\mathfrak{r}(D,p)\sum_{\tau\in\Xi_j(\mathcal{L})}\mathrm{lc}_D(i,\tau)$. With the jet exponent this is $\sum_{\mathfrak{l}} A_D(\mathfrak{l}) + \mathrm{ll}_{D,p}(\mathcal{L},i)$. □

LEAN `Data.IsGoodDatum.mem_raises`

Proposition 8.3 (moving mark operators into the data)**.** *In Settings 5.1 and 6.4, let i be a natural number and $\mathfrak{l}_1,\dots,\mathfrak{l}_n$ a list of distinct elements of $\mathcal{L}$. There is a $\mathbb{C}$-linear endomorphism t of $\mathcal{W}_i(D)$ such that for every x in the support of Ψ, with $\Phi = t\,\mathrm{td}_D(\mathsf{x},i)$:*

(a) $\omega_{D,\vartheta,i}(a,a')\Phi = t\,\omega_{D,\vartheta,i}(a,a')\mathrm{td}_D(\mathsf{x},i)$ *for all $a\in G_{X_i(D)}$ and $a'\in K_{X_{i+1}(D)}$;*

(b) for every column $\varphi\in\mathrm{Col}(D)$,

$$\mathrm{lift}_{D,\vartheta,i}(\Phi)\,\mathrm{C}_{D,\vartheta}(\mathrm{td}_D(\mathsf{x},\cdot))_i\,\varphi = \mathrm{C}_{D,\vartheta}(\mathrm{td}_D(\mathsf{x},\cdot))_{i+1}\,\Upsilon_{D,\mathcal{L}}(\mathfrak{l}_1)\cdots\Upsilon_{D,\mathcal{L}}(\mathfrak{l}_n)\varphi;$$

(c) if $i<m$: for every family $g=(g_{\mathfrak{l}})_{\mathfrak{l}\in\mathcal{L}}$ with $g_{\mathfrak{l}}=1$ for $\mathfrak{l}$ in the list and $g_{\mathfrak{l}}$ in the basic double coset of some index at most $\mathfrak{r}(D,p)$ for the other $\mathfrak{l}$,

$$\omega_{D,\vartheta,i}(1,\mathrm{at}(g))\Phi \;\in\; \mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}\!\left(1,1;p^{\sum_{c=1}^{n}(\Delta(D,p)-A_D(\mathfrak{l}_c))+\sum_{\mathfrak{l}\in\mathcal{L}}A_D(\mathfrak{l})+\mathrm{ll}_{D,p}(\mathcal{L},i)}\right).$$

Proof. Induction on the list. For the empty list take $t=1$; (a), (b) are trivial and (c) is Proposition 8.2. Let the claim hold for $\mathfrak{l}_2,\dots,\mathfrak{l}_n$ with the operator t', and write $\mathfrak{l}=\mathfrak{l}_1$. Take the numbers c_n of Proposition 8.1 for $\mathfrak{l}$ and i, put $z = p^{A_D(\mathfrak{l})}/p^{\Delta(D,p)}$ and

$$t = \Big(\sum_{n\le\mathfrak{r}(D,p)} c_n\, z\, T_{\mathfrak{l},n}\Big)\circ t',$$

the Hecke operators acting on $\mathcal{W}_i(D)$ through $a'\mapsto\omega_{D,\vartheta,i}(1,a')$; by (a) for t' and Proposition 8.1(a), $t'\mathrm{td}_D(\mathsf{x},i)$ is fixed by $K_{X_{i+1}(D)}[\mathfrak{l}]$. (a) The Hecke operators at $\mathfrak{l}$ commute with $\omega_{D,\vartheta,i}(a,a')$ for $a'\in K_{X_{i+1}(D)}$ (Input I8(ii)). (b) By the equivariance of the lift (Input I4), Hecke operators on the datum become Hecke operators on the lifted form. With C_i, C_{i+1} the chains of the statement and $\varphi' = \Upsilon_{D,\mathcal{L}}(\mathfrak{l}_2)\cdots\Upsilon_{D,\mathcal{L}}(\mathfrak{l}_n)\varphi$, which is fixed by $K_{X_0(D)}[\mathfrak{l}]$ by Lemma 6.5(c),

$$\begin{aligned}\mathrm{lift}_{D,\vartheta,i}(\Phi)\,C_i\varphi &= z\sum_n c_n T_{\mathfrak{l},n}(C_{i+1}\varphi')\\ &= z\,p^{\Delta(D,p)}\,C_{i+1}(T_{\mathfrak{l},\mathfrak{r}(D,p)}\varphi') = C_{i+1}\,\Upsilon_{D,\mathcal{L}}(\mathfrak{l})\varphi',\end{aligned}$$

by the induction hypothesis, Proposition 8.1(b) and the definition of the mark operator. (c) Expand each $T_{\mathfrak{l},n}$ as a sum over coset representatives; each term is

$\omega_{D,\vartheta,i}(1, \mathrm{at}(g'))\, t' \mathrm{td}_D(\mathsf{x}, i)$ for a family g' that agrees with g except at $\mathfrak{l}$, where it is a representative of a basic double coset of index $n \le \mathfrak{r}(D,p)$. The induction hypothesis applies to g', and the scalar $c_n z$ has $|j(c_n z)|_p \le p^{\Delta(D,p) - A_D(\mathfrak{l})}$ because $c_n \in O_j$ for $i < m$; conclude by Input I4. □

LEAN `Data.IsGoodDatum.exists_move_markOperator`

Proposition 8.4 (the chain after the mark operators)**.** *In Settings 5.1 and 6.4, let Y be the product of the operators $\Upsilon_{D,\mathcal{L}}(\mathfrak{l})$ over all $\mathfrak{l} \in \mathcal{L}$, in a chosen order, and let $v \in \mathrm{Col}_j(D)$. Then the form $\mathrm{B}_D(\vartheta, \Psi)(Y^m v)$ has j-gauge at most $p^{\sum_{i<m}(\#\mathcal{L}\cdot\Delta(D,p) + \mathrm{ll}_{D,p}(\mathcal{L},i))}$ at 1.*

Proof. For each i take the operator t_i of Proposition 8.3 for the list of all elements of $\mathcal{L}$. By (b) and induction on i, the chain of i lifts with the data $t_{i'} \mathrm{td}_D(\mathsf{x}, i')$ applied to v equals the chain with the data $\mathrm{td}_D(\mathsf{x}, i')$ applied to $Y^i v$. By (a) the t_i commute with the levels, and by (c) for the family $g = 1$ the datum $t_i \mathrm{td}_D(\mathsf{x}, i)$ lies in $\mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(1, 1; p^{\#\mathcal{L}\Delta(D,p) + \mathrm{ll}_{D,p}(\mathcal{L},i)})$. So Proposition 5.5, with $d_i = 1$, bounds the gauge of the chain combination at $Y^m v$. The restriction restr_D does not increase gauges at 1 when $p \ne N(D)$ (unit 141), and $p \ne N(D)$ by Lemma 6.5(b). □

LEAN `Data.IsGoodDatum.gaugeLe_markOperator_pow` · unit 141: `Data.GaugeLe.restrictToY`

9 The image of the mark operators has small index

Input I10 (twisted Hecke operators; unit 144). Let $n \ge 1$ be a natural number, W a valuation ring and R a commutative ring. *Twisting data* T for (n, W, R) are a prime number p_T, a natural number o, ring homomorphisms $\phi_s : W \to R$ for $s \in \mathbb{Z}/n$ (the *letters*), a parity (even or odd) for each $s \in \mathbb{Z}/n$, and an element of R with square p_T, such that $5 \le p_T^o$, p_T divides $\phi_{s+1}(y) - \phi_s(y)^{p_T^o}$ for all s and y, the parities of s and $s+1$ differ, and the residue field of W has $(p_T^o)^n$ elements. For natural numbers q', o, n, k', a', r', l' and real numbers c_1, c_2, c_3, the *Hecke sizes* are the conditions: $0 < r'$, $2r' \le k'$, $c_1 \le 1 \le c_2$, $2l' = n$, $n\,a'k'(l'+2) + a' + k' < {q'}^{l'}$, $6(2(k'+k'^2)o\,n^2 + 2) + 2 \le c_2$, $2(n+2)k'/c_2 \le c_1$, $(c_2 + n(k'+1))\,k'\,{q'}^{3r'} + k' + 2 \le a'/c_2$ and $n\,a'\,(q'^{-2r'} + r'^2/(k'q')) \le c_3$. The theorem of unit 144 on the elementary divisors of a Frobenius-twisted Hecke operator says: under the Hecke sizes and if p_T is not a unit of R, an operator given on the image M of an R-linear map from functions on a finite set of classes by the twisted formula of that unit, with an injective source map, has type $(p_T, s, (c_3 + c_1 s + c_2) \cdot n_M)$ on M for every natural number s, where n_M is the number of classes times the number of Weyl indices.

LEAN unit 144: `TwistingData`, `HeckeSizes`, `TwistingData.hasType_twisted_hecke`

Proposition 9.1 (the type of a mark operator, from twisting data)**.** *In Setting 6.4, let $\mathfrak{l} \in \mathcal{L}$, let W be the valuation ring of $E(D)$ at $\mathfrak{l}$, $n \ge 1$ a natural number, and T twisting data for (n, W, O_j) with prime p_T, exponent o and letters ϕ_s, such that p_T is not a unit of O_j and $p_T = p$. Let t be a bijection from $\mathbb{Z}/n$ onto the set of the places $\tau \in \mathrm{tops}(D)$ with $\mathfrak{l}_j(\tau) = \mathfrak{l}$ or $\mathfrak{l}_j(\tau) = \bar{\mathfrak{l}}$, such that ϕ_s is the restriction of $\iota_{t(s)}$ to W if s is even and of $y \mapsto \iota_{t(s)}(\overline{y})$ if s is odd; assume $A_D(\mathfrak{l}) = a(D) \cdot \#\{s \in \mathbb{Z}/n : \ s \text{ even}\}$, and let l' be a natural number and c_1, c_2, c_3 real numbers such that the Hecke sizes*

hold for $(p^o, o, n, k(D), a(D), \mathfrak{r}(D,p), l'; c_1, c_2, c_3)$. *Then for every natural number* s *the mark operator* $\Upsilon_{D,\mathcal{L}}(\mathfrak{l})$ *has type* $(p, s, (c_3 + c_1 s + c_2)\cdot \dim_{\mathbb{C}} \mathrm{Col}(D))$ *on* $\mathrm{Col}_j(D)$.

Proof. This is a translation into the terms of Input I10. By Lemma 3.2(d) and Input I1, evaluation at representatives g_c of the classes of $K_0^{\mathrm{col}}(D)$, chosen integral above p, identifies $\mathrm{Col}(D)$ with the functions on the classes with values in $\mathbb{C}^{\mathrm{Wy}_{X_0(D)}(\varkappa_D)}$, and $\mathrm{Col}_j(D)$ with the functions with values in $O_j^{\mathrm{Wy}_{X_0(D)}(\varkappa_D)}$ (Input I1, last property of the gauge); this is the map of Input I10, and $\dim \mathrm{Col}(D)$ is the number n_M. The Hecke operator $T_{\mathfrak{l},\mathfrak{r}(D,p)}$ on a form fixed by $K_{X_0(D)}[\mathfrak{l}]$ is the sum, over the cosets β of the parahoric subgroup of $\mathrm{GL}_{k(D)}(W)$ of block sizes $(\mathfrak{r}(D,p), k(D)-\mathfrak{r}(D,p))$, of the translates by $\beta\cdot \mathrm{diag}(p1_{\mathfrak{r}(D,p)}, 1)$. Write $g_c\cdot \mathrm{at}(\beta\ \mathrm{diag}(p1_{\mathfrak{r}(D,p)}, 1)) = \gamma\, g_{c'}\, a$ with γ rational and a in the level; then the translate of the form at g_c is $\rho_{\varkappa_D, \mathrm{last}_D(0,\cdot)}(\gamma)$ applied to its value at $g_{c'}$. At the places $t(s)$ this matrix is, since the weight there is a single row of length $a(D)$, a symmetric power of the image of γ under the letter ϕ_s, or of its inverse transpose for odd s (unitarity); together with the factor $p^{A_D(\mathfrak{l})} = p^{a(D)\#\{s \text{ even}\}}$ this is the twisted formula. At the other places τ, either τ is not a top and the weight is trivial below the rank $k(D)$, or τ induces neither $\mathfrak{l}$ nor $\bar{\mathfrak{l}}$ and γ is integral and invertible there, so the matrix is integral and invertible. The source map $(c,\beta)\mapsto c'$ together with the coset is injective because the level is free. The formal proof checks these points in 35 steps, of which the last fifteen (the identification of the letter matrices and of the powers of p) were read and not replayed. □

LEAN `Columns.hasType_markOperator`

Proposition 9.2 (the type of a mark operator)**.** *In Setting 6.4, let* s *be a natural number and* $\mathfrak{l}\in\mathcal{L}$. *Then* $\Upsilon_{D,\mathcal{L}}(\mathfrak{l})$ *has type*

$$\Big(p,\ s,\ (128\, A_D(\mathfrak{l})\cdot \frac{\log b}{m\, p} + \frac{s}{x^{14}} + x^{40})\cdot \dim_{\mathbb{C}} \mathrm{Col}(D)\Big) \quad \text{on } \mathrm{Col}_j(D).$$

Proof. $\mathcal{L}$ is not empty, so p is served: p is inert, $o = o_0(D,p)$ is odd and $o \le \mathfrak{r}(D,p)$; moreover $p \ge 13$ (unit 152). Let τ_0 be a top inducing $\mathfrak{l}$ (M3) and $v = [-p]_D^o$, of order n; then $o\,n$ is the order of $[-p]_D$, which m divides (Lemma 6.1(b)), so n is even. Put $t(s) = v^s\tau_0$ for $s\in\mathbb{Z}/n$. By Lemmas 6.2(d) and 6.1(d), t is a bijection onto the tops that induce $\mathfrak{l}$ or $\bar{\mathfrak{l}}$, and by Lemma 6.2(c) consecutive places induce conjugate primes; call s even if $t(s)$ induces $\mathfrak{l}$. The letters ϕ_s of Proposition 9.1 map W into O_j, and $\phi_{s+1}\equiv \phi_s^{p^o}$ modulo p: both sides are ring homomorphisms from W to O_j/p that agree on a root of unity of order $N_1(D)$ and on $\sqrt{-d}$, by the Frobenius criterion of unit 152. The residue field of $\mathfrak{l}$ has $p^{o\,n}$ elements (unit 152, as $o n$ is even), a square root of p lies in O_j, and $A_D(\mathfrak{l}) = a(D)\cdot\#\{s \text{ even}\} = a(D)\,n/2$. These are twisting data. The Hecke sizes hold with $l' = n/2$, $c_1 = x^{-14}$, $c_2 = x^{40}$ and $c_3 = 128\, A_D(\mathfrak{l})\log b/(mp)$: the formal text derives the three conditions that are not immediate size comparisons from $p\ge 9$, from $o\,n \ge m \ge 2\log b$, from $p^{\,o\cdot 3\mathfrak{r}(D,p)} \le b^{1/2}$ (as $p < x_1$) and from $p^{\,2\mathfrak{r}(D,p)} \ge m^2$. Proposition 9.1 gives the claim. □

LEAN `Data.IsMarked.hasType_markOperator` · unit 152: `Parameters.frob_ext`, `Parameters.q_eq_inert`, `Parameters.thirteen_le_of_chiK_ne_one`

Corollary 9.3 (the type of the product)**.** *In Setting 6.4, let* Y *be the product of the operators* $\Upsilon_{D,\mathcal{L}}(\mathfrak{l})$ *over all* $\mathfrak{l}\in\mathcal{L}$, *in a chosen order. Then* Y^m *has type* $(p,\ \mathrm{jc}(D,p),\ 3\,\mathrm{loss}(D,p)\cdot \dim_{\mathbb{C}} \mathrm{Col}(D))$ *on* $\mathrm{Col}_j(D)$.

Proof. Types add (Input I2), so by Proposition 9.2 the operator Y^m has type $(p, \mathrm{jc}(D,p), c \cdot \dim \mathrm{Col}(D))$ with

$$c = m \sum_{\mathfrak{l} \in \mathcal{L}} \Big(128\, A_D(\mathfrak{l}) \frac{\log b}{mp} + \frac{\mathrm{jc}(D,p)}{x^{14}} + x^{40} \Big).$$

Now the sum of the numbers $A_D(\mathfrak{l})$ is at most $a(D)\,\#\mathrm{tops}(D) \le a(D) f(D)$, the set $\mathcal{L}$ has at most $f(D)$ elements, $\mathrm{jc}(D,p) \le 2mf(D)a(D)/p + 1$, and $f(D)(\log b)^2 a(D)/p \le \mathrm{loss}(D,p)$ (Lemma 6.1(c)); by size, $c \le 3\mathrm{loss}(D,p)$. □

LEAN `Data.IsMarked.hasType_prod_markOperator_pow`

10 The level prime

Setting 10.1 (the level prime as p)**.** Setting 2.1 holds, and Setting 2.2 holds with $p = N(D)$: $j\colon \mathbb{C} \to \mathbb{C}_{N(D)}$ is a ring homomorphism; we write N for $N(D)$ and $|\cdot|_N$ for the absolute value of $\mathbb{C}_N$. ϑ is a twist of D. The set $\mathcal{N}$ of the conjugates $\overline{\mathfrak{l}_j(\tau)}$, $\tau \in \mathrm{Pl}(D)$, of the induced primes is a *split level* for $N(D)$ in the sense of unit 141 (the properties of Lemma 3.1(c)), and this fact is an argument of the statements below.

Input I11 (names at the level prime; unit 141). In Setting 10.1: for a function F on matrices over $\prod_{w\in\mathcal{N}} E(D)_w$ and a datum v, the *name* $F\otimes v$ is the datum obtained from v by replacing its component at the places of $\mathcal{N}$ and their conjugates by F; $\mathbf{1}_{\mathrm{lc}}$ is the indicator function of the integral matrices whose last column is congruent to $(0,\dots,0,1)$ modulo N. For a natural number i, $d_i \in G_{X_i(D)}$ is the point with component $\mathrm{diag}(1,\dots,1,N)$ at the places of $\mathcal{N}\cap \mathrm{Pl}_\pi(D)$ and 1 at the other places of $\mathcal{N}$; it has the property that restr_D maps forms of j-gauge at most c at d_m to forms of j-gauge at most c at 1. F is the *Fourier operator* on $\mathrm{St}_0(D)$: a sum, over the vectors y modulo N with unit last entry, of an additive character of the last entry times the translate by an integral matrix with last row and last column y, followed by the translate by the inverse of $\mathrm{diag}(1,\dots,1,N)$, all through the embedding of the general linear group at $\mathcal{N}$ conjugated by d_0. A pair of general linear elements at $\mathcal{N}$ acts on a name through the function, up to the values $\det_{\chi,n}(g)=\prod_{w\in\mathcal{N}}\chi_w(\det g_w)\,|\det g_w|_w^{-n/2}$ of the characters χ of the lifts. (i) A chain of pairs of lifts whose steps are equivariant up to characters equals a scalar times the chain of the modified data applied to a power of the Fourier operator. The scalar is a product over the pairs; the factor of a pair is the product of two values $\det_{\chi,n}(\delta)$ at matrices δ that are $\mathrm{diag}(1,\dots,1,N)$ at some places of $\mathcal{N}$ and 1 at the others, of a natural number, and, for each of the lifts up to the second lift of the pair, of one quotient $\det_{\chi,n}(\delta)\cdot\det_{\chi,n'}(\delta')^{-1}$ of two such values for one character χ, with $n'\le n$ and matrices δ, δ' of this kind at the same places (their sizes may differ). Moreover, for such χ, δ, δ' and $n'\le n$: $|j(\det_{\chi,n}(\delta))|_N \le |j(\det_{\chi,n'}(\delta'))|_N$ (the absolute value does not increase with the exponent). (ii) There is a natural number $e'\le 4\,m\,f(D)\,b\cdot\dim_{\mathbb{C}}\mathrm{Col}(D)$ such that the module of the $\varphi\in\mathrm{Col}(D)$ for which $\mathrm{F}^{m/2}\varphi$ is a column of j-gauge at most 1 at d_0 has index dividing $N^{e'}$ in $\mathrm{Col}_j(D)$. (iii) The components at $\mathcal{N}$ of the elements of the column levels, conjugated by the points d_i, are integral with last column congruent to $(0,\dots,0,1)$ modulo N. (iv) For a modulus $\mathfrak{m}$ of $E(D)$, an integer g' of $E(D)$ with $g'\in\mathfrak{m}$ and an integral finite adele η with $\eta\in\mathfrak{m}\,\widehat{\mathcal{O}}_{E(D)}$, the name of a function modulo $\mathfrak{m}$ with integral values, applied to a datum u, is a finite combination $\sum_y c_y\mathrm{U}(y)\mathrm{P}u$ of translates of the projection $\mathrm{P}u$ of u at the places of $\mathfrak{m}$, with every entry of $\overline{\eta}\,y$ integral and every $\mathrm{N}(g')^{\mathrm{rank}}c_y$ integral at all primes; here $\mathrm{N}(g')$ is the absolute norm of g' and rank the number of entries of y (unit 150, the lemma on admissible combinations; the two elements play different roles: g' gives the denominator, η the support).

Lemma 10.2 (character values at the level prime)**.** *In Setting 10.1, let $i\le 2m$, n and i' be natural numbers and S a set of finite places. Let χ be the character of the lift i twisted by ϑ^i, after base change, and δ_S the matrix over $\prod_{w\in\mathcal{N}}E(D)_w$, indexed by the elements of $X_{i'}(D)$ other than the last, with component $\mathrm{diag}(1,\dots,1,N)$ at the places of S and 1 elsewhere. Then $|j(\det_{\chi,n}(\delta_S))|_N \le N(D)^{2f(D)b}$.*

Proof. By Input I11(i) the absolute value does not increase when n is replaced by 0; so let $n = 0$, where $\det_{\chi,0}(\delta_S) = \prod_w \chi_w(\det \delta_{S,w})$. The character has weights $-\mathrm{wt}_D(i,\tau)$, so $|j(\chi(u))|_N$ is the product over τ of the absolute values of the components of u at the induced primes to the powers $\pm\mathrm{wt}_D(i,\tau)$; for the determinant of δ_S each component is N or 1. Hence each factor is 1 or $N^{\pm\mathrm{wt}_D(i,\tau)}$, which is at most $N^{\mathrm{wt}_D(i,\tau)} \le N^{2b}$ by the bound of unit 152 for $i \le 2m$, whatever the set S; and there are $f(D)$ factors. □

LEAN `Data.norm_detCharAt_diagN_le`

Lemma 10.3 (the indicator of the last column raises gauges little)**.** *In Setting 10.1, let* x *be a tuple of translations and* $i < m$ *a natural number. Then*

$$\mathbf{1}_{\mathrm{lc}} \otimes \mathrm{td}_D(\mathsf{x}, i) \;\in\; \mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(1, 1; N(D)^{\,f(D)b}).$$

Proof. Let $c_0 = (1+\sqrt{-d})/2$. The residue field of the prime induced at the unit place has N elements, so c_0 is congruent to an integer n modulo it; put $y_0 = c_0 - n \in \mathcal{O}_{K(P)}$. Then $j(y_0)$ is not a unit, and $j(\overline{y_0}\, d)$ is a unit: $\overline{y_0} = 1 - 2n - y_0$ and $(2c_0 - 1)^2 = -d$ is not zero modulo N. Apply Input I11(iv) to a modulus $\mathfrak{m}$ whose places are those of $\mathcal{N}$, to $g' = N$ and to $\eta = \overline{y_0}$. Both lie in every place of $\mathcal{N}$: for N this is Setting 10.1; and y_0 lies in the induced prime $\mathfrak{l}_j(\tau)$ for every τ, because $\iota_\tau(y_0) = y_0$ and $j(y_0)$ is not a unit, so $\overline{y_0}$ lies in $\overline{\mathfrak{l}_j(\tau)}$. Hence the name is a combination of translates $\mathrm{U}(y)\mathrm{Ptd}_D(\mathsf{x}, i)$ with $y_0 y$ integral, and with coefficients whose multiples by $\mathrm{N}(N)^{\,\mathrm{rank}}$ are integral. Each translate lies in $\mathrm{Std}_{y_0}(D, i)$: the projection of the datum is 0 or a translate $\mathrm{U}(y')\theta^{\circ}_{D,i}$ of the integral vacuum by a matrix that is integral at the places above N, hence a generator, and translations by the matrices y preserve the module (unit 150). So $\mathrm{N}(N)^{\,\mathrm{rank}}$ times the name lies in $\mathrm{Std}_{y_0}(D, i)$ and, by Input I8(i), raises gauges by at most $(|j(\overline{\pi_g(D)})|_N / |j(\overline{y_0} d)|_N)^L \le 1$. Now N is a rational integer and $E(D)$ has degree $2f(D)$, so $\mathrm{N}(N) = N^{2f(D)}$; and the rank of the space of homomorphisms is $n_i(D) n_{i+1}(D) \le n_m(D)^2$. Dividing by $\mathrm{N}(N)^{\,\mathrm{rank}}$ therefore costs at most $N^{2f(D) n_m(D)^2}$, which is at most $N^{f(D)b}$ because $2\, n_m(D)^2 \le b$ by size. (The norm of y_0 plays no part: its valuation at N is not bounded.) □

LEAN `Data.name_lastColDatum_mem_raises` · unit 150: `Parameters.finHeisOp_mem_standardData`

Proposition 10.4 (the paired chain at ramified columns)**.** *In Setting 10.1 there is a complex number* z *with* $|j(z)|_N \le N(D)^{\,2mf(D)b}$ *such that for every family* $v = (v_i)_{i \in \mathbb{N}}$ *with* $v_i \in \mathcal{W}_i(D)$ *and every* $\varphi \in \mathrm{Col}^{\mathrm{ram}}(D)$

$$\mathrm{C}^{(2)}_{D,\vartheta}(\nu \mapsto \mathrm{pt}_D(\mathrm{P}^{\mathrm{Pl}_\pi(D)} v)_\nu)_{m/2}\, \varphi = z \cdot \mathrm{C}_{D,\vartheta}((\omega_{D,\vartheta,i}(d_i, d_{i+1})(\mathbf{1}_{\mathrm{lc}} \otimes v_i))_i)_m\, \mathrm{F}^{m/2}\varphi.$$

Proof. The sum over y in Definition 2.8(b) is a sum of names: translating by $-y/N$ in the last column, or its conjugate in the last row, multiplies the component at $\mathcal{N}$ by a character of the last column, respectively row, and $\mathrm{diag}(1, \dots, 1, N)$ splits off the places of $\mathrm{Pl}_\pi(D)$. Each pair of lifts is then equivariant, up to the values $\det_{\chi,n}$, under the general linear groups at $\mathcal{N}$; the characters are unramified at the places above N. Input I11(i) gives the identity for ramified φ (ramified columns are ramified in the sense of unit 141, by Lemma 4.3(b)). The scalar z is a product over the $m/2$ pairs. By Input I11(i) the factor of a pair consists of two values $\det_{\chi,n}(\delta)$ of characters of the chain, each of absolute value at most $N^{2f(D)b}$ by Lemma 10.2; of a natural number, of absolute value at most 1; and of quotients $\det_{\chi,n}(\delta) \cdot \det_{\chi,n'}(\delta')^{-1}$ with $n' \le n$, each of absolute value at most 1 by the monotonicity in the exponent (an

upper bound for a value alone would say nothing about its inverse; the exponents are ranks $n_i(D)$, which increase with i). Hence $|j(z)|_N \le (N^{2f(D)b})^{2\cdot m/2} = N^{2mf(D)b}$. □

LEAN `Data.chain₂_pairTranslates_eq_smul_chain`

Proposition 10.5 (the chain at the level prime)**.** *In Setting 10.1, let Ψ be a finitely supported complex function on the tuples of translations of D such that Ψ is good for (D,ϑ), and let $\varphi \in \mathrm{Col}^{\mathrm{ram}}(D)$ be such that $\mathrm{F}^{m/2}\varphi$ is a column of j-gauge at most 1 at d_0. Then $\mathrm{B}_D(\vartheta,\Psi)\varphi$ has j-gauge at most $N(D)^{3mf(D)b}$ at 1.*

Proof. By (G3) and Proposition 10.4 with $v_i = \mathrm{td}_D(\mathsf{x},i)$, the chain combination at φ is z times the chain combination with the data $t_i\mathrm{td}_D(\mathsf{x},i)$, $t_i = \omega_{D,\vartheta,i}(d_i,d_{i+1})(\mathbf{1}_{\mathrm{lc}}\otimes\cdot\,)$, at $\mathrm{F}^{m/2}\varphi$. The operators t_i commute with the levels on these data: by Input I11(iii) the level elements, conjugated by the d_i, preserve the last column modulo N, hence the indicator. By Lemma 10.3 and the definition of the set of raising data, $t_i\mathrm{td}_D(\mathsf{x},i) \in \mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(d_i,d_{i+1};N^{f(D)b})$. Now N is prime to $\mathrm{nrm}(\vartheta)$ (Input I3), so Proposition 5.5 applies and gives gauge at most $N^{mf(D)b}$ at d_m; multiply by $|j(z)|_N \le N^{2mf(D)b}$ and restrict (Input I11). □

LEAN `Data.gaugeLe_Bmu_at_N`

11 Proof of Theorem B

Lemma 11.1 (four gauge bounds for the chain)**.** *In Setting 5.1, let $v \in \mathrm{Col}_j(D)$.*

(a) If $p \neq N(D)$ and $p \neq d$, then $\mathrm{B}_D(\vartheta,\Psi)v$ has j-gauge at most 1 at 1.

(b) If $\mathcal{L}$ is a full mark and Y is the product of the operators $\Upsilon_{D,\mathcal{L}}(\mathfrak{l})$ over all $\mathfrak{l}\in\mathcal{L}$, in a chosen order, then $\mathrm{B}_D(\vartheta,\Psi)(Y^m v)$ has j-gauge at most $p^{2\mathrm{loss}(D,p)-\mathrm{gain}(D,p)}$ at 1.

(c) If p is small and not split for D, then $\mathrm{B}_D(\vartheta,\Psi)v$ has j-gauge at most p^c at 1, where $c = m\cdot\mathrm{coll}(D,p,\emptyset) + \mathrm{loss}(D,p) - \mathrm{gain}(D,p)$.

(d) If p is small and not split for D, then $\mathrm{B}_D(\vartheta,\Psi)(p^{\mathrm{jc}(D,p)}\cdot v)$ has j-gauge at most $p^{\mathrm{loss}(D,p)-\mathrm{gain}(D,p)}$ at 1.

Proof. (a) By Lemma 5.3 with $\delta = \pi_g(D)$ every datum lies in $\mathrm{Std}_{\pi_g(D)}(D,i)$, so by Input I8(i) it lies in $\mathrm{Raise}_{\mathrm{k}_{D,\vartheta,i}}(1,1;c)$ with $c = (|j(\overline{\pi_g(D)})|_p/|j(\overline{\pi_g(D)}d)|_p)^L = |j(d)|_p^{-L} = 1$, as $p \neq d$. Proposition 5.5 with $t_i = 1$, $d_i = 1$, $r_i = 0$ and the restriction (unit 141, $p \neq N(D)$) give the claim.

(b) By Proposition 8.4 the exponent is at most

$$\sum_{i<m}\Big(\#\mathcal{L}\cdot\Delta(D,p) + \mathfrak{r}(D,p)\sum_{\tau\in\Xi_j(\mathcal{L})}\mathrm{lc}_D(i,\tau) - \mathrm{je}_D(p,i,\Xi_j(\mathcal{L}))\Big).$$

The place 1 is a top, so $\mathcal{L}$ is not empty and p is served, $\chi_{K(P)}(p) = -1$. By Lemma 7.4, Proposition 7.3 with $\Xi = \Xi_j(\mathcal{L})$ and Lemma 7.1(d), each summand is at most

$$\frac{\mathrm{loss}(D,p)}{m} - \frac{\mathrm{gain}(D,p)}{m} + f(D)(\log b)^2\frac{a(D)}{pm} \;\le\; \frac{2\mathrm{loss}(D,p)-\mathrm{gain}(D,p)}{m}\,;$$

the two terms $\#(\mathrm{tops}(D)\cap\Xi_j(\mathcal{L}))\,a(D)/x_1$ cancel, and the last step is Lemma 6.1(c).

(c) The empty set is marked, by (M4); for it $Y = 1$, $\Xi_j(\emptyset) = \emptyset$ and $\mathrm{ll}_{D,p}(\emptyset, i) = -\mathrm{je}_D(p, i, \emptyset)$. By Propositions 8.4 and 7.3, the exponent is at most

$$\sum_{i<m}\Big(-\frac{\mathrm{gain}(D,p)}{m} + \mathrm{coll}(D,p,\emptyset) + f(D)(\log b)^2\frac{a(D)}{pm}\Big),$$

and Lemma 6.1(c) applies again.

(d) $\mathrm{B}_D(\vartheta, \Psi)$ is linear, so the gauge of (c) is multiplied by $p^{-\mathrm{jc}(D,p)}$. By Lemma 7.1(b) with $o = 1$, $m\,\mathrm{coll}(D,p,\emptyset) \le 2mf(D)a(D)/p \le \mathrm{jc}(D,p)$. □

LEAN Data.IsGoodDatum.gaugeLe_one · Data.IsGoodDatum.gaugeLe_Bmu_of_isMarked · Data.IsGoodDatum.gaugeLe_collisionSum · Data.IsGoodDatum.gaugeLe_pow_jetCeil_smul

Proof of Theorem B. If a form has j-gauge at most p^c at 1 with $c \le -\beta$, then its multiple by $p^{-\beta}$ has j-gauge at most 1 at 1. Three cases, following the definition of $\mathrm{err}(D,p)$.

$p \in \mathrm{NS}(D)$. Then p is a prime below x_1 with $\chi_{K(P)}(p) \ne 1$, $\mathrm{err}(D,p) = 3\mathrm{loss}(D,p)$, $\mathrm{loss}(D,p) \ge 1$ by size and Lemma 6.1(c), and the hypothesis reads $\beta < \mathrm{gain}(D,p) - 3\mathrm{loss}(D,p) + 1$; so $2\mathrm{loss}(D,p) - \mathrm{gain}(D,p) \le -\beta$. If p is served, take a full mark $\mathcal{L}$ (Lemma 6.3), the operator Y of Lemma 11.1(b) and

$$S = Y^m\,\mathrm{Col}_j(D) + p^{\mathrm{jc}(D,p)}\,\mathrm{Col}_j(D).$$

By Corollary 9.3 there is a natural number $l \le 3\mathrm{loss}(D,p)\dim\mathrm{Col}(D)$ such that S has index dividing p^l in $\mathrm{Col}_j(D)$. An element of S is $Y^m u + p^{\mathrm{jc}(D,p)}v$ with $u, v \in \mathrm{Col}_j(D)$, and by Lemma 11.1(b) and (d) both parts are mapped to forms of gauge at most $p^{-\beta}$. If p is not served, take $l = 0$ and $S = \mathrm{Col}_j(D)$: by Lemma 11.1(c) and Lemma 7.1(c) the gauge is at most $p^{2\mathrm{loss}(D,p)-\mathrm{gain}(D,p)}$. In this case the columns need not be ramified.

$p \notin \mathrm{NS}(D)$ and $p = N(D)$. Then $\mathrm{err}(D,p) = 4mf(D)b$ and $\beta < 1 - 4mf(D)b$, so $3mf(D)b \le -\beta$, as $mf(D)b \ge 1$. Take for S the module of Input I11(ii) and $l = e'$. For a ramified column $\varphi \in S$, Proposition 10.5 gives gauge at most $N^{3mf(D)b}$. (Here $N(D)$ is prime to $\mathrm{nrm}(\vartheta)$ for every twist, and Setting 10.1 holds with the given j.)

The other primes. Then $\mathrm{err}(D,p) = 0$, $\beta \le 0$, and we take $l = 0$, $S = \mathrm{Col}_j(D)$. Since $p \ne N(D)$, and $p \ne d$ because d is a prime below x_1 with $\chi_{K(P)}(d) = 0$ and so belongs to $\mathrm{NS}(D)$, Lemma 11.1(a) applies. □

LEAN Data.exists_indexDvd_Bmu_divisible

12 Sizes: Theorems C and D

Lemma 12.1 (the prime sum, prime by prime)**.** *In Setting 2.1, let U be a natural number with $\lceil x_1\rceil \le U$, y a real number with $y \le a(D)$ and $\tau \in \mathrm{Pl}(D)$. Then*

$$\mathrm{Ask}_D(y,\tau) = \sum_{p<U,\ p\ prime} 2\,\mathrm{ask}_{D,p}(y,\tau)\cdot\log p.$$

Proof. The weight is $\lambda_{d,1}(\nu) = \Lambda(\nu)(1-\chi_{K(P)}(\nu))$, with Λ the von Mangoldt function. The term of index $\nu \ge \lceil x_1\rceil$ of $\mathrm{Ask}_D(y,\tau)$ vanishes, because $y/\nu \le a(D)/x_1$ and every nominal weight is at least $a(D)/x_1$; and $\lceil x_1\rceil \le a(D)$ by size. So the sum may be taken over all $\nu \ge 1$, and since Λ is supported on the prime powers it is $\sum_p\sum_{e\ge1}\log p\,(1-\chi_{K(P)}(p)^e)\,(y/p^e - w_D([-p^e]_D\cdot\tau))_+$. In each of the cases $p = d$, $\chi_{K(P)}(p) = 1$, $\chi_{K(P)}(p) = -1$ one has $1-\chi_{K(P)}(p)^e = 2\cdot\frac{1-\chi_{K(P)}(p)}{2}\cdot[e \text{ odd or } p = d]$ for $e \ge 1$. The primes $p \ge \lceil x_1\rceil$ contribute 0. □

LEAN `Data.primeSum_eq_sum_localAsk`

Lemma 12.2 (row lengths)**.** *In Setting 2.1, let $i < m$ and ν be natural numbers and $\tau \in \mathrm{Pl}(D)$. The row of index ν at τ of the diagram of $\varkappa_D$ for the rank $n_{i+1}(D)$ has length*

$$\sum_{\nu<h<n_{i+1}(D)} \varkappa_D(\tau,h) \;\le\; \big([\nu=0]\,\varkappa_D(\tau,1) + [0<\nu<k(D)]\,\mathrm{wt}_D(0,\tau)\big) + \big([\nu=0]\,(b_1(D)+b_2(D)) + r^{16}\big),$$

where $b_1(D)$ and $b_2(D)$ are the least multiples of $N_1(D)$ that are at least $a(D)/x$ and $a(D)/x_1$.

Proof. Bound each $\varkappa_D(\tau,h)$ with $h \neq 1$ by $[h=k(D)]\mathrm{wt}_D(1,\tau)+\mathrm{gap}(D)$ (unit 150); here $\mathrm{wt}_D(1,\tau) = \mathrm{wt}_D(0,\tau)+\mathrm{gap}(D)$, $\mathrm{wt}_D(0,\tau) \le b_1(D)+b_2(D)+r^8$, the height $k(D)$ occurs only for $\nu < k(D)$, and $(n_m(D)+2)\mathrm{gap}(D) \le r^{16}$ by size. □

LEAN `Data.diagramWeight_le_by_index`

Lemma 12.3 (two sizes)**.** *In Setting 2.1:*

(a) For every $\sigma \in \mathrm{Aut}(\mathbb{C})$, $|\sigma(\overline{\pi_g(D)})|^2 = g(D)$.

(b) For natural numbers n, n', e with $n \le n'+e$, $\mathrm{st}_D(n) \le \mathrm{st}_D(n') + (\log(n'+e+1) - \log(\Omega(P,\mu(D))/g(D)))\cdot e$.

Proof. (a) σ maps $K(P)$ to itself, by the identity or by conjugation, and $\pi_g(D)\overline{\pi_g(D)} = g(D)$. (b) First $n! \le (n'+e)! \le n'!\,(n'+e+1)^e$. Secondly the number $-\log(\Omega(P,\mu(D))/g(D))$ is non-negative by size, so its multiple by n is at most its multiple by $n'+e$. □

LEAN `Data.norm_map_star_piG_sq` · `Data.jetSize_le_add`

Lemma 12.4 (the number of classes)**.** *In Setting 2.1, let I be a finite set and K a subgroup of G_I.*

(a) If $G \ge 1$ is a natural number, $|I| \le 2\,n_m(D)$ and $K_I(G) \subseteq K$, then $\#\mathrm{Cl}(K) \le \exp(x^{29}(1+\log G))$.

(b) If $K_I(\overline{\pi_g(D)}\,\pi_N(D)) \subseteq K$ and $|I| \le n_m(D)$, then $\#\mathrm{Cl}(K) \le \exp(x^{30})$.

Proof. (a) The classes of K map onto those of K_I with fibres of at most $[K_I : K] \le [K_I : K_I(G)]$ elements; this index is at most a power of the norm of G, with exponent $|I|^2$ (background library), and the number of classes of K_I is at most $(1+2(6N'(f(D)|I|)^2)^3)^{4f(D)|I|^2}$ for $N' = N_1(D)\,d$, a number in the different (unit 149, from the short bases of Input I7). Take logarithms and compare by size. (b) Apply (a) with $G = g(D)\,N(D)$, which $\overline{\pi_g(D)}\pi_N(D)$ divides, and $x^{29}(1+\log(g(D)N(D))) \le x^{30}$ by size. □

Input I12 (sizes of one lift and of the restriction; units 143 and 141). In Setting 2.1, let $\sigma \in \mathrm{Aut}(\mathbb{C})$. (i) For every form $\varphi \in \mathrm{St}_m(D)$ and every $h \in G_{Y_m(D)}$, $\|\sigma \circ (\mathrm{restr}_D\,\varphi)(h)\|^2 \le \exp(x^{70} - \sum_\tau \mathrm{be}_D(\tau) \cdot \log N(D)) \cdot \|\sigma \circ \varphi(\mathrm{bd}_D(h))\|^2$. (ii) Let i be a natural number, $\Phi = \mathrm{U}(y)\theta^{\circ}_{D,i}$ a translate of the integral vacuum, g, h points and $L \ge 1$ a natural number. Then for every vector ξ, with $l(\tau,\nu)$ the length of the row ν at τ for the rank $n_{i+1}(D)$,

$$\sqrt{\|\sigma \circ \mathrm{jm}_{D,1,i}(\omega_{D,1,i}(g,h)\Phi)\xi\|^2} \le \exp\Big(c_i + \tfrac{1}{2}\sum_\tau \sum_{\nu<n_i(D)} \big(\tfrac{l(\tau,\nu)}{L} + \mathrm{st}_D(l(\tau,\nu))\big)\Big) \cdot \sqrt{\|\sigma \circ \xi\|^2},$$

where c_i is the constant of the parameters times $(N_1(D)\, n_i(D) n_{i+1}(D) + 1)^2$, plus $f(D)\, n_i(D) n_{i+1}(D) \log(2L+2)$.

LEAN unit 141: `Data.weylNormSq_restrictToY_le` · unit 143: `Parameters.norm_jet_le_of_isAdmissibleComb`, second part, for an admissible combination of one term

Proof of Theorem C. The claim without prime sums. By Lemma 12.1 with $U = \lceil x_1 \rceil$ and the definitions of $\mathrm{gain}(D,p)$ and $\mathrm{forced}(D,p)$, and because $\mathrm{gain}(D,p) = 0$ when $\chi_{K(P)}(p) = 1$,

$$2 \sum_{p \in \mathrm{NS}(D)} \mathrm{gain}(D,p) \log p = m\Big(\sum_{\tau \in \mathrm{tops}(D)} \mathrm{Ask}_D(a(D),\tau) + k(D) \sum_\tau \mathrm{Ask}_D(w_D(\tau),\tau)\Big).$$

These are exactly the prime sums of $h_{\mathrm{row}}(D)$, so the exponent in Theorem C is

$$B + m\Big(\#\mathrm{tops}(D) \cdot \mathrm{st}_D(a(D)) + k(D) \sum_\tau \mathrm{st}_D(\mathrm{wt}_D(0,\tau))\Big) - \#\mathrm{tops}(D) \cdot a(D) \log N(D) + \mathrm{budget}(D),$$

a statement about sizes only.

The restriction. By Input I12(i) and Lemma 3.3(a), the restriction costs the factor $\exp(x^{70} - \sum_\tau (\varkappa_D(\tau,1) - 2b) \log N(D)) = \exp(x^{70} + 2bf(D) \log N(D) - \#\mathrm{tops}(D) a(D) \log N(D))$.

The chain. Apply Lemma 5.4 to the data $\mathrm{td}_D(\mathsf{x}, i)$, jointly invariant by (G2), with $\mathrm{N}_i(g,\xi) = \sqrt{\|\sigma \circ \xi\|^2}$ and with r_i the factor of Input I12(ii) for $L = a(D) + 1$. The value of the chain combination at a point is a sum of at most $\prod_{i<m} \#\mathrm{Cl}(K_i^{\mathrm{col}}(D)) \le \exp(m\, x^{30})$ terms (Lemmas 12.4(b) and 3.2(a)) for each x, each of norm at most $|\sigma(\Psi(\mathsf{x}))| \cdot \prod_i r_i \cdot \mathrm{e}^{B/2}$; the norm $\sqrt{\|\sigma \circ \cdot\|^2}$ satisfies the triangle inequality, and $\sum_{\mathsf{x}} |\sigma(\Psi(\mathsf{x}))| \le \exp(x^{60})$ by (G1), since $Q(1) = \emptyset$.

The exponent. It remains to bound $\prod_i r_i^2$. In stage $i < m$ the rows are bounded by Lemma 12.2: the row $\nu = 0$ at a top has length at most $a(D) + e$ with $e = b_1(D) + b_2(D) + r^{16}$, the rows $0 < \nu < k(D)$ have length at most $\mathrm{wt}_D(0,\tau) + r^{16}$, and the other rows have length at most r^{16} (and $b_1(D) + b_2(D) + r^{16}$ for $\nu = 0$ off the tops). By Lemma 12.3(b) each $\mathrm{st}_D(l(\tau,\nu))$ exceeds $\mathrm{st}_D(a(D))$, $\mathrm{st}_D(\mathrm{wt}_D(0,\tau))$ or $\mathrm{st}_D(0) = 0$ by at most the excess of the row length times the factor $\log(2a(D)+1) - \log(\Omega(P,\mu(D))/g(D))$; this factor is at most m by size. Summing over $\nu < n_i(D)$, over τ and over the m stages gives $m(\#\mathrm{tops}(D) \cdot \mathrm{st}_D(a(D)) +$

$(k(D)-1)\sum_\tau \mathrm{st}_D(\mathrm{wt}_D(0,\tau)))$, since the rows $0<\nu<k(D)$ are $k(D)-1$ in number. This is at most the main term of the display above, because $\mathrm{st}_D(n)\ge 0$ for every n: $-\log(\Omega(P,\mu(D))/g(D))\ge 0$ by size. The remaining terms, namely c_i, $l/L\le 2$, the excesses, $m\,x^{30}$, x^{60}, x^{70} and $2bf(D)\log N(D)$, are bounded by $\mathrm{budget}(D)$; the formal text does this by a chain of size comparisons (through b and $\sqrt{b}$) that was read and not replayed. □

LEAN `Data.weylNormSq_Bmu_le`

Proof of Theorem D. Let $p\in U$. If $p\in \mathrm{NS}(D)$ then $p\le\lfloor x_1\rfloor$, $\log p\le\log x_1$ and $\mathrm{err}(D,p)\log p\le 3f(D)(\log b)^2a(D)\log x_1\cdot m^*/p$, where $m^*=m$ if p is short for D and 1 otherwise. If p is short, $p=mc\pm1$ for a natural number c with $1\le c\le x_1$, and $m/p\le 2/c$; if not, $m^*/p=1/p$, and put $c=p$. If $p=N(D)\notin\mathrm{NS}(D)$, the term is $4mf(D)b\log N(D)$. So every term is bounded by a term attached to a pair (c,n), $1\le c\le\lfloor x_1\rfloor$, $n\in\{0,1,2,3\}$, namely $3f(D)a(D)(\log b)^2\log x_1\cdot 2/c$, the prime p being the n-th entry of $(N(D),mc-1,c,mc+1)$; different primes of U have different pairs. Summing over all pairs, with $\sum_{c\le x_1}1/c\le 1+\log x_1$,

$$\sum_{p\in U}\mathrm{err}(D,p)\log p\;\le\;4\cdot 6\,f(D)a(D)(\log b)^2\log x_1\,(1+\log x_1)\;\le\;f(D)a(D)(\log b)^3,$$

the last step by the condition $(\log x_1)^6\le\log b$ of the data and by size; the term of $N(D)$ is bounded by the term of the pair $(1,0)$, by $m\log N(D)\le 30m^2\log b$, $m^2\le 4x$ and $x\,b\le a(D)$. □

LEAN `Data.sum_allowedLoss_mul_log_le`

13 A by-product: the determinant period

The first part of the file on the chain serves another unit (the value families of the unit on Selmer groups). It is independent of the data D.

Definition 13.1 (determinant kernel and determinant period)**.** Let E be a CM field with a CM type and Weil data, I a finite set, α a continuous character of the norm-one adeles of E that is trivial on the norm-one elements of E, c a function $\mathrm{Pl}(E)\to\mathbb{N}$, $\mathfrak{m}$ a modulus of E (a non-zero ideal divisible by no prime together with its conjugate), Ψ' a complex function on the matrices indexed by I over $\mathcal{O}_E/\mathfrak{m}$, and $(\psi_w)_w$ a family of characters of the residue fields of the finite places.

(a) $\mathrm{dk}_I^{\alpha,c}[\mathfrak{m};\Psi']$ is the function $h\mapsto\theta_{\alpha,\alpha}[\Psi',\prod_\tau\det_\tau^{c(\tau)}](1,h)$ on G_I: the theta kernel of the pair (E^I,E^I) with both characters equal to α, the finite datum given by Ψ' modulo $\mathfrak{m}$ and the polynomial $\prod_\tau\det_\tau^{c(\tau)}$ ($\det_\tau$ the determinant of the matrix of variables at τ), at the points $(1,h)$.

(b) $\mathrm{dp}_I^{\alpha,c}[\mathfrak{m};\psi]$ is the sum over the classes of K_I, weighted by the inverses of the orders of their stabilisers, of the function $\mathrm{dk}_I^{\alpha,c}[\mathfrak{m};\chi_{\mathfrak{m},\psi}\circ\det]$, where $\chi_{\mathfrak{m},\psi}(y)=\prod_{w\mid\mathfrak{m}}\psi_w(y \bmod w)$.

LEAN `detKernel` · `detPeriod` · background library: `modKernelI`, `letterMinor`, `stdClassSum`, `Modulus.charOfTamePart`

Lemma 13.2 (invariance and expansion)**.** *In the situation of Definition 13.1, assume that α has weight $-c$ at the infinite places and tame part $(\psi_w)_w$.*

(a) For every Ψ', every $\gamma\in\Gamma_I$ and every $g\in G_I$: $\mathrm{dk}_I^{\alpha,c}[\mathfrak{m};\Psi'](\gamma g)=\mathrm{dk}_I^{\alpha,c}[\mathfrak{m};\Psi'](g)$.

(b) *If $\psi_w = 1$ for every w that does not divide $\mathfrak{m}$, then $\mathrm{dp}_I^{\alpha,c}[\mathfrak{m};\psi]$ is the weighted sum over the classes of K_I of the function $g \mapsto \sum_y \mathrm{dk}_I^{\alpha,c}[\mathfrak{m};\mathbf{1}_1](g\tilde{y})$, where y runs over the invertible matrices over $\mathcal{O}_E/\mathfrak{m}$, $\tilde{y} \in K_I$ is a chosen lift of y, and $\mathbf{1}_1$ is the indicator function of the unit matrix.*

Proof. (a) The polynomial is a product of determinants of the stacked matrix of variables, and for such polynomials the kernel is invariant under the rational points on the left (unit 143), the characters having the weight $-c$. (b) Expand $\chi_{\mathfrak{m},\psi} \circ \det$, which vanishes on the singular matrices, as $\sum_y \chi_{\mathfrak{m},\psi}(\det y)\mathbf{1}_y$; right translation by $\tilde{y}$ moves $\mathbf{1}_1$ to $\mathbf{1}_y$ and multiplies by $\alpha(\det \tilde{y})$, which is $\chi_{\mathfrak{m},\psi}(\det y)$ by the hypothesis on the tame part (background library). □

LEAN `detKernel_embFin_mul` · `detPeriod_eq_stdClassSum_sum` · unit 143: `modKernel_embFin_mul` · background library: `modKernel_mul_Kf_right`

Proposition 13.3 (adding a place to the modulus)**.** *In the situation of Definition 13.1, assume that α has weight $-c$ at the infinite places and tame part $(\psi_w)_w$, and that $\psi_w = 1$ for every w that does not divide $\mathfrak{m}$. Let v be a finite place that does not divide $\mathfrak{m}$ and $\mathfrak{m}'$ a modulus whose places are those of $\mathfrak{m}$ together with v. Then*

$$\mathrm{dp}_I^{\alpha,c}[\mathfrak{m}';\psi] = \prod_{l<|I|} (1 - \mathrm{q}_v^l\, \alpha_v^{-1}) \cdot \mathrm{dp}_I^{\alpha,c}[\mathfrak{m};\psi],$$

where α_v is the value at a uniformiser of v of the Hecke character of α, normalised by $\mathrm{q}_v^{|I|/2}$.

Proof. α is unramified at v, and v is not conjugate to a place of $\mathfrak{m}'$. The local computation behind Input I9(iv), which the catalogue marks as substantial (the action of the Hecke coset sums on the unramified vacuum, by counting subspaces of the residue space), shows that the datum for $\mathfrak{m}'$, which differs from that for $\mathfrak{m}$ by the indicator of the invertible matrices at v, is obtained from it by the Hecke polynomial at $X = \alpha_v^{-1}$ acting through the Weil representation. Both class sums are class integrals of functions that are invariant on the left by Lemma 13.2(a) and on the right under K_I; the Hecke polynomial then becomes a sum over coset representatives, each contributing the same integral, and the count of the cosets is the q-binomial theorem $\sum_V (-X)^{\dim V} \mathrm{q}_v^{\binom{\dim V}{2}} = \prod_{l<|I|}(1 - \mathrm{q}_v^l X)$, the sum over the subspaces V of the residue space. □

LEAN `detPeriod_insert` · background library: `sum_heckePolyCoeff_smul_pairWeil`, `q_binomial_submodule` (the q-binomial theorem; the catalogue: the theorem itself, place not confirmed)

14 Where the results are used

By a search of the sources for the names of the declarations: Theorems A, B, C and D, with the definitions of $h_{\mathrm{row}}(D)$, $\mathrm{NS}(D)$ and $\mathrm{err}(D,p)$, are used in the file of the endgame that proves Theorem A of the handout (short forms). Proposition 4.5 is used by the unit on the filling, for the dimension of the ramified columns in Theorem B of the handout. Proposition 4.2 is used by the unit on the exchange, for its crude rows; Lemma 12.1 by the unit on the rows; the determinant period of §13 by the unit on Selmer groups (its value families). The definitions of the columns, of the levels, of the restriction and of good data (Definitions 2.3, 2.4, 2.7, 2.8) are used by the units on the seesaw and on the exchange; the seesaw unit proves that good

data exist and that the rows of the handout are of the form $\mathrm{B}_D(\vartheta,\Psi)\psi$. I read the statements of these consumers only where this note quotes them.

15 Notes on the formal text

1. *Arguments: the text reading and Lean.* Nothing was compiled, so the argument lists of the declarations are those that a program reads from the text, and in this folder they differ from Lean's in several places, because section variables are declared again and included or omitted by commands. The statements above follow the Lean text, as I read it; the points that only Lean can settle are these. *Entries of the text reading that are not arguments*: a place w dividing $\pi_N(D)$ in Definition 2.7(d) (the operator takes the data and a set of places; the note writes $\mathrm{ram}_D(\Sigma)$ through a macro of its own with these two arguments), in Lemma 3.2(e), (g) and in Lemma 5.2(a); a number called j with its primality in Definition 2.8(b), Lemma 5.4 and Proposition 5.5 (in Lemma 3.2(h) the same variable is the prime that the note calls ℓ); the exponent e in Definition 2.9(a) and Lemma 7.1(b); the set $\mathcal{L}$ in Lemma 6.3; the prime p and its place in Theorem C; ϑ and Ψ in Theorem B, which the statement binds; a second record of data in Lemma 5.2(a), where the formal statement names only one; the Weil data and other instances of variables that were declared again, in Definition 2.5, Lemma 4.1, Proposition 4.2 and Definition 2.7(a). *Arguments that the text reading does not show*: that Ψ is good and p is prime to $\mathrm{nrm}(\vartheta)$ in the four parts of Lemma 11.1 (a command includes these hypotheses again); that $\mathcal{L}$ is marked in Proposition 8.3 (used after the first local definition of the statement); the prime p and the homomorphism j in Lemma 3.2(i), Lemma 6.2(b), Lemma 6.5(a), (c) and Lemma 6.6. The note states all of them, through the Settings.

2. *Statements that the line reading cuts.* The formal statements of Propositions 8.1 and 8.3 contain local definitions, and the program takes their first sign of definition for the end of the statement; the two propositions were compared with the full Lean text. The same program counts the command that follows Lemma 10.3 and the one that follows Theorem C into these declarations; they make some definitions opaque and are no part of the proofs.

3. *Hypotheses that follow from others, or are used in one case only.* In Proposition 8.1 the hypothesis $\bar{\mathfrak{l}} \neq \mathfrak{l}$ follows from (M1). In Theorem B the columns have to be ramified only for $p = N(D)$. In the definition of $\mathrm{err}(D,p)$ the case $p = N(D)$ is tested after $p \in \mathrm{NS}(D)$; by size $N(D) \geq x_1$, so the order does not matter. Lemma 5.4 takes functions N_i and numbers r_i for all i and uses those with $i \leq m$. In Proposition 9.1 the equalities "W is the valuation ring at $\mathfrak{l}$" and $p_T = p$ are hypotheses of the formal statement.

4. *Forms of the statements.* Integrality of a column is the condition "j-gauge at most 1 at 1"; Theorem B(ii) is, in the formal text, membership of $p^{-\beta}\mathrm{B}_D(\vartheta,\Psi)\varphi$ in the module of such forms on $Y_m(D)$. Theorem B(i) uses the notion of index of unit 149 (Input I2), which is stated without quotient modules. In (G3) the numbers of pairs and of lifts are written with $\lfloor m/2 \rfloor - 1$. The jet exponent contains the term $e = 0$ for $p = d$. The definition of the restriction contains the proof that it maps forms to forms. Lemma 3.2(b) and Lemma 6.1(a) are

instances in the formal text: the first is found by Lean whenever a level is needed, the second feeds the tactic of size comparisons.

5. *What was not replayed.* The dossier marks as of lower confidence the claims made for dense automatic steps, whose intermediate goals are not visible without Lean. I read these lines; I could not replay them. They are: the extraction of the coefficients and the exponent count in Proposition 8.1; the identification of the letter matrices in Proposition 9.1; which of the Hecke sizes each line proves in Proposition 9.2; the rewriting of the paired chain in Proposition 10.4; the size comparisons at the end of the proofs of Theorems C and D; and the two computations in Proposition 13.3. For Proposition 7.3 the formal text proves the termwise inequality (2) by one automatic step after a case split; the proof given above is mine and was checked against the formal definitions, not against the automatic step. Three counts that an earlier version of this note left to the formal text are now written out and were compared with the source: the constant of Proposition 4.2, the exponents of the diagonal point in Proposition 8.2 (the image at τ reads the component at the conjugate of the induced prime), and the denominator and the scalar at the level prime (Lemma 10.3, Proposition 10.4).
6. *Size comparisons.* Many steps are comparisons of sizes of the data, proved in the formal text by a tactic from the scale conditions; the dossier does not record the exponents, and the note says "by size". They belong to the note on the admissible data.
7. *What the final theorems use.* The dossier found no member of the unit that is evidently unused; the count of the members reached from the final theorems by name alone is not meaningful here, and a kernel export will decide.
8. *References.* For the inputs from the background library the catalogue of the handout gives a reference only for the Hecke transfer (Input I9(iv), place not confirmed, a special case) and for the q-binomial theorem (the theorem, place not confirmed); for the others: *reference to be confirmed.* The headers of the files of this folder name as related work, without places: for the scaled Hecke operators, Rallis (1982), V. Lafforgue (2011) and Z. Liu (2025); for the divisibility of theta lifts, X. Zhang (2022), Berger (2009) and Prasanna (2006); for short columns, Gross (1999), Greenberg–Voight (2014) and the geometry of numbers of Minkowski and Mahler; for the elementary divisors of twisted Hecke operators, Arsovski (2019), Liu–Truong–Xiao–Zhao (2023) and Fakhruddin–Pilloni (2021). I did not check these.

How this note was written. From the dossier of the unit: the readings of its 105 declarations and its 46 structured proofs, all of which I read, with the reader's list of doubts. The program check of the dossier covered 331 leaf steps of 46 proofs. I read the seven Lean files of the folder completely, statements and proofs, and compared every statement of this note with its Lean text, argument by argument, with the program's list of arguments beside it. Outside the folder I read the Lean definitions of the objects of Inputs I2 to I6 (index and type, the level prime and the twists, the lift kernel, the data and the chain, induced primes and marked sets, the bookkeeping of unit 150 in its file), the definitions of gauges, levels, classes, kernels, lifts and Hecke operators at split places in the background library, and the statements, not

the proofs, of the results quoted in Inputs I7 to I12. The arrangement into sections, the remark that the prime sums cancel in Theorem C, the proof of (2) and the presentation of the proof of Theorem D are mine; elsewhere the proofs follow the structured proofs, with bookkeeping steps merged.

In these texts `D.ramifiedColumns` is $\mathrm{Col}^{\mathrm{ram}}(D)$, `IsShort` the notion of Definition 2.5, `D.budget` is $\mathrm{budget}(D)$, `integralColumns` is $\mathrm{Col}_j(D)$, `IndexDvd` the index of Input I2, `Bμ θ Ψ` is $\mathrm{B}_D(\vartheta, \Psi)$, `IsGoodDatum θ Ψ` says that Ψ is good for (D, ϑ), `θ.levelNorm` is $\mathrm{nrm}(\vartheta)$, `integralFormsAt ⊤ 1` is the module of the forms of gauge at most 1 at 1, `weylNormSq` is the Gram norm, `D.heightPerRow` is $h_{\mathrm{row}}(D)$, `D.nonsplitPrimes` is $\mathrm{NS}(D)$ and `D.allowedLoss` is $\mathrm{err}(D, p)$. Elsewhere the letters of the formal text were changed where the write-up reserves them: the stage `j` is i and the homomorphism `ιₚ` is j; the element `θ` of the null cone is ϖ_0, as in the note on the CM curve; the exponent `s` of the data is $\mu(D)$; a place `σ` is τ; a marked set `∧` is $\mathcal{L}$ and its elements `l` are $\mathfrak{l}$; a prime `w` dividing `D.π` is $\mathfrak{p}$; a tuple of translations `x` is x; the set `ev` is Ξ; `κ` is $\varkappa$; the number of boxes `N` is L; `D.ϱ + 1` is $m/2$.

Notation

$P = (N_0, d)$, D parameters; admissible data for P (Setting 2.1)

x, x_1, b, m, r components of D: the three scales, the number of lifts, the rank of the rows

$\mu(D)$, $E(D)$, $N_1(D)$, $f(D)$ the exponent, the CM field, the order of its roots of unity, the number of its infinite places

$K(P)$, $\chi_{K(P)}$ $\mathbb{Q}(\sqrt{-d})$ and its quadratic character

$\mathrm{Pl}(D)$, τ, τ', τ_0, τ_e the group of infinite places of $E(D)$; places; $\tau_e = [-p^e]_D \cdot \tau$

ι_τ, $[\nu]_D$ the embedding at τ; the place named by the integer ν

$k(D)$, $t(D)$, $a(D)$, $n_i(D)$ $r + 1 - m$; $5r$; the order of the jets; the ranks $k(D) + i(t(D) + 1)$

$\mathrm{tops}(D)$, $\mathrm{thick}(D)$, $w_D(\tau)$, $\mathrm{wt}_D(i, \tau)$, $\mathrm{gap}(D)$ tops, thick places, nominal weight, weights, the gap $2r^8$

$\mathrm{budget}(D)$ $f(D)a(D)(\log b)^3$

E, $\mathrm{Pl}(E)$, $\mathcal{O}_E$, $\widehat{\mathcal{O}}_E$, $\mathbb{A}_{E,\mathrm{f}}$ a CM field; its infinite places, integers, integral adeles, finite adeles

w, $\overline{w}$, E_w, $\mathfrak{q}_w$, v a finite place, its conjugate, the completion, the size of the residue field; v also a finite place, or a column, or a family of data, where said

p, j, $\mathbb{C}_p$, $|\cdot|_p$, $\mathfrak{o}_p$, O_j a prime (a natural number where said); a ring homomorphism $\mathbb{C} \to \mathbb{C}_p$; the absolute value; the valuation rings (Setting 2.2)

ℓ, ι a prime number; a ring homomorphism $\mathbb{C} \to \mathbb{C}_\ell$

σ, $\mathrm{Aut}(\mathbb{C})$ an automorphism of $\mathbb{C}$; the group of all of them

I, I' finite index sets

f the number of infinite places of a CM field E

$\varkappa$, $\mathfrak{e}$, h, c, c' column counts; determinant exponents; a height; Weyl indices (tableaux); c also a real or complex constant, a class, a list index, a function $\mathrm{Pl}(E) \to \mathbb{N}$, where said

G_I, Γ_I, K_I, $K_I(a)$, $K_I[w]$ finite adelic unitary group, its rational points, the standard level, principal levels, the group at w (Input I1)

K, J, $\mathrm{Cl}(K)$, χ levels; classes; a character of a level, or of a lift

g, h, k, a, a', d, d', d_i, y, y', y'' points of the groups; y also a matrix over the adeles, a vector of residues, a real number, or an integer, where said

$\mathrm{Wy}_I(\varkappa)$, $\rho_{\varkappa,\mathfrak{e}}$, ξ, ξ' Weyl indices, the weight representation, vectors of the weight

$\mathrm{Alg}_I(\varkappa,\mathfrak{e})$, φ, φ', φ_0, ψ, $\mathrm{R}(g)$ algebraic forms; forms and columns; right translation

$\mathrm{gauge}_j^{\varkappa,\mathfrak{e}}(g;\xi)$, $\|\xi\|^2$, G the gauge at j; the Gram norm and its matrix

$\mathrm{boxes}(\varkappa,n')$, L, $l(\tau,\nu)$ numbers of boxes; row lengths

O, V, M, S, u, z, s, l Input I2: a ring, a module, submodules, a matrix, a scalar, an exponent, a natural number; S also a set of places, M a natural number, z a complex number, s a number of lifts or an element of $\mathbb{Z}/n$, V a subspace, where said

$X_i(D)$, $Y_m(D)$, i, i' index sets of the definite spaces; stages

$N(D)$, N, $\pi_N(D)$, $g(D)$, g_0, g_1, $\pi_g(D)$ the level prime (written N where said), an integer of norm N, the product of the two primes of the data, an integer of $K(P)$ of norm $g(D)$

N' a natural number in the different of a CM field; for $E(D)$ it is $N_1(D)\,d$

$K_I^{\mathrm{ch}}(D)$ the chosen level

ϑ, $Q(\vartheta)$, ψ_w, $\mathrm{nrm}(\vartheta)$ a twist, its set of places, its tame part, the product of the norms

$\mathcal{W}_i(D)$, $\mathrm{U}(y)$, $\theta^\circ_{D,i}$, P^Σ finite data, Heisenberg operators, the integral vacuum, a projection (Input I4)

$\mathrm{k}_{D,\vartheta,i}$, $\omega_{D,\vartheta,i}$, $\mathrm{jm}_{D,\vartheta,i}$, $\mathrm{lift}_{D,\vartheta,i}$ the lift kernel, its representation, its jet matrix, the lift

$\mathrm{Raise}_k(d,d';c)$ data that multiply gauges by at most c from d to d'

x, $\mathrm{td}_D(\mathsf{x},i)$, Φ, Φ', $\Phi^{(2)}$, Ψ, Ψ' tuples of translations, their data; data; a function on tuples; a function on matrices

$\mathrm{C}_{D,\vartheta}(\Phi)_s$, $\mathrm{C}^{(2)}_{D,\vartheta}(\Phi)_s$, C, C_i, $\mathrm{B}_D(\vartheta,\Psi)$ chains of lifts and of pairs; the chain followed by the restriction

$\mathrm{Col}(D)$, $\mathrm{Col}^{\mathrm{ram}}(D)$, $\mathrm{Col}_j(D)$, $\mathrm{St}_i(D)$ columns, ramified columns, j-integral columns, stages

$\mathrm{Pl}_\pi(D)$, $\mathfrak{p}$, Σ, $K_i^{\mathrm{col}}(D)$ the primes dividing $\pi_N(D)$, one of them, a set of them; the column levels

lst_D, bd_D, $\mathrm{be}_D(\tau)$, $\mathrm{Br}(D)$, restr_D Definition 2.4

φ is B-short, B, B' short forms; real bounds

$\mathfrak{c}_D(\mathfrak{p})$, cen_D, $\mathrm{ram}_D(\Sigma)$, ν Definition 2.7; ν an adele, an integer, or the index of a row or of a pair, where said

$\mathrm{Adm}_D(q)$, q, $\mathrm{pt}_D(v)_\nu$, Ψ is good for (D,ϑ) Definition 2.8

$\mathfrak{l}_j(\tau)$, $\mathcal{L}$, $\mathfrak{l}$, $\Xi_j(\mathcal{L})$, $A_D(\mathfrak{l})$, $\mathrm{lc}_D(i,\tau)$, $\mathrm{lb}_D(i,\tau)$ Input I5

$\mathrm{ask}_{D,p}(y,\tau)$, $\mathrm{forced}(D,p)$, $\mathrm{gain}(D,p)$, $\mathrm{loss}(D,p)$, $\mathfrak{r}(D,p)$, $\Delta(D,p)$, $\mathrm{jc}(D,p)$, $o_0(D,p)$, $\mathrm{coll}(D,p,\Xi)$, Ξ, e, $\mathrm{cc}_p(\varkappa,n';\Xi;\tau,\tau';e)$, $\varkappa_D(\tau,h)$, $\mathrm{last}_D(i,\tau)$, $\mathrm{kept}_D(h)$, $\varkappa_D^Y(\tau,h)$, $\varrho_d(p)$ Input I6

$\mathrm{je}_D(p,i,\Xi)$, $\mathrm{ll}_{D,p}(\mathcal{L},i)$, $\Upsilon_{D,\mathcal{L}}(\mathfrak{l})$, $T_{w,s}$, Y Definition 2.9; Hecke operators; the product of the mark operators

$h_{\mathrm{row}}(D)$, $\mathrm{NS}(D)$, $\mathrm{err}(D,p)$, $\mathrm{st}_D(n)$, $\mathrm{Ask}_D(y,\tau)$, $\mathsf{U}(D)$, $\lambda_{d,1}(\nu)$, $\Omega(P,\mu(D))$, Λ Definition 2.10; Λ the von Mangoldt function

β, U, η, δ, δ_S, ω an integer; a finite set of numbers, a natural number or a complex variable; $a(D)/(pm)$; an integer of $K(P)$; a diagonal matrix; in $\omega_{D,\vartheta,i}$

$\mathrm{Lat}(\delta;S)$, $\mathrm{Std}_\delta(D,i)$, $\mathrm{ThProd}_{P,\mu}(\delta,r;I)$, s_1, $\mathrm{per}(P,\mu)$, Θ, ϖ, ϖ_0, T objects of unit 150 (Inputs I8, I9); ϖ also a uniformiser (Input I8); T also twisting data

N_i, r_i, t_i, t, t', β_c, $\mathcal{C}_i$ sizes, factors, operators on the data, linear maps, properties (Inputs I8, Lemma 5.4); t also a bijection, r a real number

n, n', n'', o, o', k', a', r', l', q', c_0, c_1, c_2, c_3, c_n, e' natural numbers and constants defined where they occur

one_τ, low_τ, bx_τ; lv_e, $\mathrm{cl}_{\tau,e}$ the three counts in the coupling count (Input I6); the indicators of live pairs and of collisions (proof of Proposition 7.3)

$\mathrm{col}(z)$, $\mathrm{row}(z)$, $\mathrm{at}(g)$, $\mathrm{ev}(y)$, $\mathrm{sq}(y)$ matrices with one non-zero column or row; the point of a family of local matrices; evaluation vectors; the square matrices of the first columns of a point (Input I7)

ch, ϵ_τ, $J_{\mathfrak{l}}$, u_τ charges; exponents of a diagonal point; sets of indices; diagonal entries

p_T, ϕ_s, ϕ, W, R, X, Π, α, α', α_v, α_e, H twisting data and Hecke polynomials: a prime, the letters, ring homomorphisms, a valuation ring (also a subspace), a ring or a bound, a variable, a polynomial, values of characters; α also a character

$\mathcal{N}$, $\mathbf{1}_{\mathrm{lc}}$, F, F, $\mathfrak{m}$, $\mathfrak{m}'$, g', y_0 Setting 10.1 and Input I11: the split level, an indicator, a function, the Fourier operator, moduli, integers; in Input I11(iv) also an integral adele η, and $\mathrm{N}(g')$ the absolute norm

$b_1(D)$, $b_2(D)$, m^*, γ, A, A_ϕ, $Y(g)$, $c_{\tau,\nu}$ multiples of $N_1(D)$; a factor of the loss; a rational point; matrices of the proof of Proposition 4.2

$\mathrm{dk}_I^{\alpha,c}[\mathfrak{m};\Psi']$, $\mathrm{dp}_I^{\alpha,c}[\mathfrak{m};\psi]$, $\chi_{\mathfrak{m},\psi}$, $\tilde{y}$ Definition 13.1

e, π, θ the base of the natural logarithm; in $\pi_N(D)$, $\pi_g(D)$; in $\theta^{\circ}_{D,i}$

READBACK NOTE 40

Elementary divisors of a Frobenius-twisted Hecke operator

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. A group $\mathrm{GL}_k(W)$ over a local ring with finite residue field acts on forms in L sets of k variables, through L ring homomorphisms that are linked in a circle by a power of Frobenius modulo a prime p, alternately directly and by the inverse transpose. A Hecke operator of this action, scaled by powers of p so as to be integral, is shown to have small elementary divisors: modulo p^e its cokernel has length at most a small share of e times the rank, plus a constant times the rank. Four ideas carry the proof. A *root lemma*: a term of a form that is least, for valuation plus a weight, among all translates under a Levi subgroup has exponents that obey linear inequalities, by a count of zeros against degree. Two *dimension bounds* modulo p: forms whose exponents nearly obey these inequalities in all frames fill about one part in the degree of the operator, by a count of flags against the volume of a cone of cyclically interlacing vectors; and forms that the scaling makes divisible in all frames are rare. An *approximate projector* onto the first kind of forms, made from conjugation-invariant means on polynomials in generic matrices. And normal forms of matrices over a valuation ring, which turn the three into a statement about indices.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, of the Riemann hypothesis and of its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles with Lean v4.35.0 against a pinned version of the library Mathlib and that Lean's kernel accepted the proofs; an independent build is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note treats one unit of the artifact, the folder on the twisted Hecke operator: 75 of its 78 declarations, which are all that carry a name (the others are three instances, described in §11). Proofs are given in full, *given* four inputs from other units: the calculus of index divisibility (unit 149), the Hermite and Smith normal forms over a valuation ring, a combinatorial Nullstellensatz with multiplicity, and the order of the general linear group of a finite field. Standard facts of algebra and of measure theory are used without proof: Nakayama's lemma, the freeness of a finitely generated torsion-free module over a valuation domain, the vanishing of the trace of a nilpotent endomorphism of a free module of finite rank over a domain, Legendre's formula for the power of a prime in a factorial, the change of variables for Lebesgue measure under a linear map, and the convergence of normalised counts of lattice points to the volume of a bounded convex set. Every statement of the unit and of the Inputs was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 86 declarations.

1 The statements

The notions are defined in §2; here is what is needed to read the five theorems. *Twisting data* T of length L over a local ring W and a ring $\mathcal{O}$ are a prime p, a power $P_T = p^o \geq 5$, ring homomorphisms $\iota_s \colon W \to \mathcal{O}$ for $s \in \mathbb{Z}/L$ (the *letters*) with $\iota_{s+1}(v) \equiv \iota_s(v)^{P_T}$ modulo p for v in W, a parity of the letters that alternates, and an element ϖ of $\mathcal{O}$ with $\varpi^2 = p$; the residue field of W has $q_T = P_T^L$ elements. An element γ of $\mathrm{GL}_k(W)$ acts on the variables $x_{i,s}$ $(0 \leq i < k,\ s \in \mathbb{Z}/L)$ of letter s through the matrix $\gamma_{T,s}$, which is $\iota_s(\gamma)$ for even s and $\iota_s((\gamma^{-1})^{\mathsf{T}})$ for odd s; $[\gamma]_T$ is this action on polynomials, and $\rho_{T,n}(\gamma)$ its matrix on the forms of degree n in each letter, in the basis of the monomials x^β, $\beta \in \mathrm{Mon}^L_{k,n}$. For a pair of indices (i_0, i_1) and a letter s_0, $\mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot)$ is a real weight on the variables, the *excess weight*; for a threshold $\mathfrak{t}$, $\mathrm{depth}^{k,n}_{T,\mathfrak{t}}(\beta)$ is the degree of x^β in the variables that are *deep* for $\mathfrak{t}$. $\mathrm{Ex}^{i_0,i_1}_{T,n}(I;h)$ is the module of the forms F such that every translate of F by a block diagonal element has, modulo the ideal I, only monomials of excess at most h at every letter; $\mathrm{Dp}^{k,n}_{T,\mathfrak{t}}(j)$ is the module of the forms all of whose translates have only monomials of depth at least j. $\mathrm{Sz}(P_T, o, L, k, n, \mathfrak{t}; \lambda, \kappa, y, z)$ is a list of ten conditions on sizes (Definition 2.9).

Theorem 1 (the root lemma). *In Setting 2.2, let s_0 be a letter, let $i_0 \neq i_1$ be indices, let τ be a labelling of the indices with $\tau(i_0) = \tau(i_1)$, and let ω be a real weight on the variables with*

$$0.4 \ \leq\ \omega(\mathrm{rt}_{T,s}(i_0, i_1)) - \omega(\mathrm{rt}_{T,s}(i_1, i_0)) \ \leq\ 1.6 \qquad \text{for every letter } s.$$

Let Φ be a polynomial in the variables x_v over $\mathcal{O}$, let α be an exponent and e a natural number. Suppose that $[\gamma^{-1}]_T\Phi$ lies in $\mathrm{Gs}_{\mathrm{ad}_{\varpi}(\cdot),\omega}(e + \langle\omega, \alpha\rangle)$ for every γ in $\mathrm{Lev}_\tau(W)$: the coefficient of $x^{\alpha'}$ in every such translate is divisible by ϖ to the power $\max(\lceil e + \langle\omega, \alpha\rangle - \langle\omega, \alpha'\rangle\rceil, 0)$. Suppose that ϖ^{e+1} does not divide the coefficient of x^α in Φ. Then

$$\langle \mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot), \alpha\rangle \ \leq\ 0.$$

LEAN `TwistingData.root_lemma`

Theorem 2 (the cyclic interlacing cone fills the share of one flag). *Let $k \geq 0$ and $L \geq 1$ be integers,* par *a map from $\mathbb{Z}/L$ to the signs $\{+, -\}$, and ϱ a real number with $1 < \varrho$. Let $\delta = (\delta_s)_{s \in \mathbb{Z}/L}$ be real numbers and $\mathcal{C}$ a subset of $\mathbb{R}^{k \times L}$ such that, for every ξ in $\mathbb{R}^{k \times L}$: $\mathrm{St}_{\mathrm{par},\varrho,1}(\xi)$ lies in $\mathcal{C}$ if and only if ξ lies in $\mathrm{Pc}_{\mathrm{par},\varrho}$. Then*

$$\prod_{l=1}^{k} \frac{\varrho^{Ll} - 1}{\varrho^L - 1} \ \cdot\ \mathrm{vol}(\mathcal{C} \cap \mathrm{Sl}_k(\delta)) \ =\ \mathrm{vol}(\mathrm{Sl}_k(\delta)).$$

LEAN `prod_mul_volume_inter_slab`

The identity holds for every real $\varrho > 1$. When ϱ^L is the number q of elements of a finite field, the product is the number of full flags in a vector space of dimension k over that field.

Theorem 3 (two dimension bounds in characteristic p). *In Setting 2.2, let the ring of T be a field $\mathbb{F}$ of characteristic p, the prime of T. Let n, λ be natural numbers and κ, z real numbers.*
(a) *Let i_0, i_1 be indices with $i_0 + 1 = i_1$, and h a real number such that $\mathrm{Sz}(P_T, o, L, k, n, i_1; \lambda, \kappa, h, z)$. Then*

$$\left[\mathrm{GL}_k(W) : \mathrm{Par}_{\tau_{k,i_1}(\cdot)}(W)\right] \cdot \dim_{\mathbb{F}} \mathrm{Ex}^{i_0,i_1}_{T,n}(0; h) \;\le\; (1+\kappa) \cdot \left(\#\mathrm{Mon}_{k,n}\right)^L.$$

(b) *Let $\mathfrak{t}$ be a natural number and y a real number such that $\mathrm{Sz}(P_T, o, L, k, n, \mathfrak{t}; \lambda, \kappa, y, z)$, and let j_0 be a natural number. Then*

$$\sum_{j<j_0} \dim_{\mathbb{F}} \mathrm{Dp}^{k,n}_{T,\mathfrak{t}}(j) \;\le\; (1+z) \cdot \left(\#\mathrm{Mon}_{k,n}\right)^L.$$

LEAN TwistingData.index_mul_finrank_excessCond_le · TwistingData.sum_finrank_deepForms_le

Here $(\#\mathrm{Mon}_{k,n})^L$ is the number of the monomials x^β, the rank of the module of forms. In (a) the index of the parahoric subgroup is the number of cosets over which a Hecke operator sums, its degree; so the forms obeying the excess condition fill about one part in the degree.

Theorem 4 (an approximate projector). *In Setting 2.2, let $\mathcal{O}$ be a valuation domain of characteristic zero in which the prime p of T is not a unit. Let c, n, λ be natural numbers, i_0, i_1 indices with $i_0 + 1 = i_1$, and h a real number. Suppose that $\lambda + \lambda = L$ and $L\,n\,k\,(\lambda+2) + n + k < P_T^\lambda$. Then there are a function w from $\mathrm{Mon}^L_{k,n}$ to $\mathcal{O}$ and a square matrix Z over $\mathcal{O}$ indexed by $\mathrm{Mon}^L_{k,n}$ such that:*

(i) *ZF lies in $\mathrm{Ex}^{i_0,i_1}_{T,n}(\varpi^c\mathcal{O}; h)$ for every F in $\mathcal{O}^{\mathrm{Mon}^L_{k,n}}$;*

(ii) *for every F' in $\mathrm{Ex}^{i_0,i_1}_{T,n}(\varpi^c\mathcal{O}; h-(4c+2))$ and every F in $\mathcal{O}^{\mathrm{Mon}^L_{k,n}}$, ϖ^c divides*

$$\sum_\beta F'(\beta)\, w(\beta)\, (ZF)(\beta) \;-\; p^{(k+k^2)\,oL\cdot L} \sum_\beta F'(\beta)\, F(\beta);$$

(iii) *$w(\beta)\,\rho_{T,n}(\gamma^{\mathsf{T}})_{\beta,\beta'} = w(\beta')\,\rho_{T,n}(\gamma)_{\beta',\beta}$ for every γ in $\mathrm{GL}_k(W)$ and all β, β' in $\mathrm{Mon}^L_{k,n}$.*

LEAN TwistingData.exists_projector

Theorem 5 (elementary divisors of the twisted Hecke operator). *In Setting 2.2, let $\mathcal{O}$ be a valuation domain of characteristic zero in which the prime p of T is not a unit. Let n, $\mathfrak{t}$, λ be natural numbers and κ, y, z real numbers with $\mathrm{Sz}(P_T, o, L, k, n, \mathfrak{t}; \lambda, \kappa, y, z)$. Let $\mathcal{X}$, $\mathcal{H}$, $\mathcal{I}$ be finite sets, write $\mathcal{Q} = \mathrm{GL}_k(W)/\mathrm{Par}_{\tau_{k,\mathfrak{t}}(\cdot)}(W)$ for the finite set of left cosets, and $\mathcal{E} = \mathcal{X} \times \mathcal{Q}$. Let V be an $\mathcal{O}$-module, $\Psi\colon \mathcal{O}^{\mathcal{X}\times\mathcal{I}} \to V$ an $\mathcal{O}$-linear map, and Y an $\mathcal{O}$-linear endomorphism of V. Let $\mathrm{src}\colon \mathcal{E} \to \mathcal{X}$ be a map, $(\gamma_{\mathfrak{e}})_{\mathfrak{e}\in\mathcal{E}}$ elements of $\mathrm{GL}_k(W)$, $(u_{\mathfrak{e}})_{\mathfrak{e}\in\mathcal{E}}$ elements of $\mathrm{GL}_{\mathcal{H}}(\mathcal{O})$ (invertible matrices over $\mathcal{O}$ indexed by $\mathcal{H}$), and $\jmath\colon \mathcal{I} \to \mathrm{Mon}^L_{k,n} \times \mathcal{H}$, $\mathfrak{i} \mapsto (\beta_{\mathfrak{i}}, \mathfrak{h}_{\mathfrak{i}})$, a bijection. Suppose that the map $\mathfrak{e} \mapsto (\mathrm{src}(\mathfrak{e}), (\gamma_{\mathfrak{e}}^{\mathsf{T}})^{-1}\mathrm{Par}_{\tau_{k,\mathfrak{t}}(\cdot)}(W))$ from $\mathcal{E}$ to $\mathcal{E}$ is injective, and that for every F in $\mathcal{O}^{\mathcal{X}\times\mathcal{I}}$*

$$Y(\Psi(F)) = \Psi(F^\flat),$$
$$F^\flat(\mathfrak{x}, \mathfrak{i}) = \sum_{\mathfrak{q}\in\mathcal{Q}} \sum_{\mathfrak{i}'\in\mathcal{I}} (u_{(\mathfrak{x},\mathfrak{q})})_{\mathfrak{h}_{\mathfrak{i}}, \mathfrak{h}_{\mathfrak{i}'}} \left(H_{(\mathfrak{x},\mathfrak{q})}\right)_{\beta_{\mathfrak{i}'}, \beta_{\mathfrak{i}}} F(\mathrm{src}(\mathfrak{x}, \mathfrak{q}), \mathfrak{i}'),$$

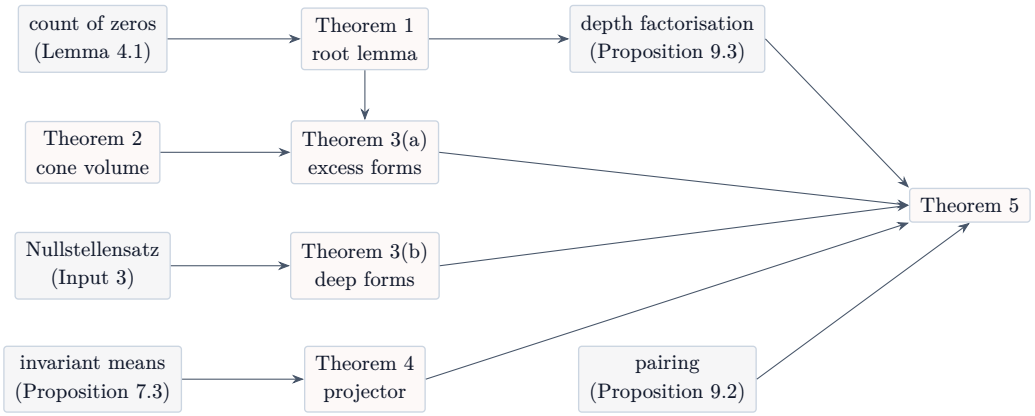
where $H_{(\mathfrak{x},\mathfrak{q})} = \rho_{T,n}(\gamma_{(\mathfrak{x},\mathfrak{q})}) \cdot \mathrm{diag}(p^{\mathrm{depth}^{k,n}_{T,\mathfrak{t}}(\beta)})_\beta \cdot \rho_{T,n}(\tilde{\mathfrak{q}}^{-1})$ and $\tilde{\mathfrak{q}}$ is the chosen representative of the coset $\mathfrak{q}$. Then, for every natural number e:

$$Y \text{ has type at most } (z + \kappa e + y) \cdot \#\mathcal{X} \cdot \#\mathcal{I} \text{ at } p^e \text{ on } \Psi(\mathcal{O}^{\mathcal{X}\times\mathcal{I}}).$$

LEAN `TwistingData.hasType_twisted_hecke`

The last line says (Input 1): Y maps the image of Ψ into itself, and the index of $Y(\operatorname{im}\Psi) + p^e \operatorname{im}\Psi$ in $\operatorname{im}\Psi$ divides p^l for a natural number $l \le (z + \kappa e + y)\,\#\mathcal{X}\,\#\mathcal{I}$. The rank of $\mathcal{O}^{\mathcal{X}\times\mathcal{I}}$ is $\#\mathcal{X} \cdot \#\mathcal{I}$; so of the $e \cdot \#\mathcal{X} \cdot \#\mathcal{I}$ units of length that p^e could cost, the operator loses the share κ, and a constant $z + y$ for each basis vector. The size conditions make κ small when y is large and n larger still. The operator $F \mapsto F^\flat$ is a sum over the cosets of the parahoric subgroup, as a Hecke operator is, of the scaling p^{depth} between two translations, twisted by the matrices $u_{\mathfrak{e}}$ on an auxiliary space and by the map src on the points.

The note on the unit of the columns (unit 145) quotes this theorem as its Input I10, with other letters: it writes n, k', a', q', r', l', c_1, c_2, c_3, ϕ_s and s for what is here L, k, n, P_T, $\mathfrak{t}$, λ, κ, y, z, ι_s and e, and it states the theorem for a valuation ring W.



How the five theorems depend on each other and on the main intermediate results.

2 The setting

Conventions. The natural numbers are $0, 1, 2, \dots$. Every ring is a commutative ring with 1. A *local ring* W has one maximal ideal $\mathfrak{m}_W$ and the residue field $\mathbb{F}_W = W/\mathfrak{m}_W$. A *valuation domain* is an integral domain in which, of any two elements, one divides the other; it is a local ring, and its maximal ideal is written $\mathfrak{m}$. The number of elements of a finite set $\mathcal{S}$ is $\#\mathcal{S}$; for the residue field of a local ring the formal text uses a count that is 0 for an infinite field (§11, note 5).

Indices, letters, variables. k and L are natural numbers, $L \geq 1$ unless said otherwise. The *indices* are $0, \dots, k-1$, written i, i', l. The *letters* are the elements of $\mathbb{Z}/L$, written s, s', s_0; $s+1$ is the next letter. A *variable* is a pair $v = (i, s)$ of an index and a letter; the set of variables is finite. A *labelling* is a map τ from the indices to the natural numbers. For a labelling τ and a local ring W, $\mathrm{Lev}_\tau(W)$ is the *Levi subgroup*, of the γ in $\mathrm{GL}_k(W)$ with $\gamma_{ii'} = 0$ whenever $\tau(i) \neq \tau(i')$, and $\mathrm{Par}_\tau(W)$ is the *parahoric subgroup*, of the γ with $\gamma_{ii'} \in \mathfrak{m}_W$ whenever $\tau(i) < \tau(i')$. For the constant labelling $\mathrm{Lev}_\tau(W) = \mathrm{GL}_k(W)$; for the labelling $i \mapsto i$, $\mathrm{Par}_\tau(W)$ consists of the matrices that are lower triangular modulo $\mathfrak{m}_W$ (the lower Iwahori subgroup).

Polynomials. For a set $\mathcal{V}$ of variables and a ring $\mathcal{O}$, $\mathcal{O}[x_\mathcal{V}]$ is the polynomial ring in the variables x_v, $v \in \mathcal{V}$. An *exponent* is a function α from $\mathcal{V}$ to the natural numbers with finite support; $x^\alpha = \prod_v x_v^{\alpha(v)}$, $|\alpha| = \sum_v \alpha(v)$ is its degree, and for a real function ω on $\mathcal{V}$, a *weight*, $\langle \omega, \alpha \rangle = \sum_v \omega(v)\alpha(v)$. The same notation is used for vectors α with real coordinates. For a square matrix G over $\mathcal{O}$ indexed by a finite set $\mathcal{V}$, the *linear substitution* of G is the endomorphism of the $\mathcal{O}$-algebra $\mathcal{O}[x_\mathcal{V}]$ with $x_{v'} \mapsto \sum_v G_{vv'} x_v$; it is multiplicative in G. $\mathrm{Mon}_{k,n}$ is the set of the exponents of degree n on the indices, and $\mathrm{Sym}^n(G)$, for G in $\mathrm{M}_k(\mathcal{O})$, is the matrix indexed by $\mathrm{Mon}_{k,n}$ whose (β, β') entry is the coefficient of x^β in the linear substitution of G applied to $x^{\beta'}$. A *family* is an element $\beta = (\beta_s)_s$ of $\mathrm{Mon}_{k,n}^L = (\mathrm{Mon}_{k,n})^{\mathbb{Z}/L}$; it is also read as the exponent $(i, s) \mapsto \beta_s(i)$ on the variables, of degree n in each letter. A *form* is a vector $F = (F(\beta))_\beta$ in $\mathcal{O}^{\mathrm{Mon}_{k,n}^L}$, also read as the polynomial $\sum_\beta F(\beta) x^\beta$. For matrices G_s indexed by $\mathrm{Mon}_{k,n}$, one for each letter, $\bigotimes_s G_s$ is the matrix indexed by $\mathrm{Mon}_{k,n}^L$ with entries $\prod_s (G_s)_{\beta_s, \beta'_s}$. Matrices act on column vectors; G^T is the transpose.

Volumes. $\mathbb{R}^{k \times L}$ is the space of the real functions on the variables, with Lebesgue measure vol; a volume is a real number, finite in all cases that occur.

Definition 2.1 (twisting data)**.** Let L be a natural number, W a local ring and $\mathcal{O}$ a ring. *Twisting data of length L over W and $\mathcal{O}$* are a tuple $T = (p, o, (\iota_s)_{s \in \mathbb{Z}/L}, \mathrm{par}_T, \varpi)$ of natural numbers p and o, ring homomorphisms $\iota_s \colon W \to \mathcal{O}$, a map par_T from $\mathbb{Z}/L$ to the signs $\{+, -\}$, the *parity* (the letter s is *even* if $\mathrm{par}_T(s) = +$ and *odd* otherwise), and an element ϖ of $\mathcal{O}$, such that: p is prime; $5 \leq p^o$; $\varpi^2 = p$ in $\mathcal{O}$; p divides $\iota_{s+1}(v) - \iota_s(v)^{p^o}$ in $\mathcal{O}$ for every letter s and every v in W; $\mathrm{par}_T(s+1) \neq \mathrm{par}_T(s)$ for every letter s; and $\#\mathbb{F}_W = (p^o)^L$. The set of all twisting data is $\mathrm{TD}_L(W, \mathcal{O})$. For T in it we put

$$P_T = p^o, \qquad q_T = P_T^L,$$

and for a ring homomorphism $\chi \colon \mathcal{O} \to \mathcal{O}'$ we write

$$\chi_* T = (p, o, (\chi \circ \iota_s)_s, \mathrm{par}_T, \chi(\varpi)),$$

an element of $\mathrm{TD}_L(W, \mathcal{O}')$.

LEAN TwistingData · TwistingData.P · TwistingData.q · TwistingData.map

For $L = 0$ there are no twisting data, as a field has at least two elements. For $L \geq 1$ the alternation forces L to be even. The components of T keep their names: p, o, ι_s, par_T and ϖ always belong to the twisting data called T in the statement at hand, and those of $\chi_* T$ are as just said.

Setting 2.2. $L \geq 1$ and $k \geq 0$ are integers, W is a local ring, $\mathcal{O}$ is a ring, and T is an element of $\mathrm{TD}_L(W, \mathcal{O})$, with components $p, o, (\iota_s)_s, \mathrm{par}_T, \varpi$. Indices, letters and variables are those of the conventions, for this k and L.

Letters. The letters of this note are local to it. The threshold of the depth is written $\mathfrak{t}$ and the parity par, because the write-up keeps μ and ς for the exponent of the data and for a root of unity. The letters λ, κ, τ, σ, m, q, θ and the polynomials Φ have no relation to the objects that the overview of the handout writes with them (an arithmetic function and a constant of Chapter I, the infinite places, the automorphisms of the complex numbers, the number of lifts, a rational number of Theorem A, the family of twists, a function of Chapter I), and P_T none to the parameters. In the application (§10) k and n become the rank of the columns and the number $a(D)$ of the data D.

Definition 2.3 (the action on forms)**.** In Setting 2.2, let γ be an element of $\mathrm{GL}_k(W)$, s a letter and n a natural number.

(a) $\gamma_{T,s}$ is the matrix in $\mathrm{M}_k(\mathcal{O})$ obtained by applying ι_s to the entries of γ if s is even, and of $(\gamma^{-1})^{\mathsf{T}}$ if s is odd. The map $\gamma \mapsto \gamma_{T,s}$ is multiplicative.

(b) $[\gamma]_T$ is the endomorphism of the $\mathcal{O}$-algebra of polynomials in the variables $x_{i,s}$ that acts on the variables of each letter s by the linear substitution of $\gamma_{T,s}$. The map $\gamma \mapsto [\gamma]_T$ is multiplicative: $\mathrm{GL}_k(W)$ acts on the left.

(c) $\rho_{T,n}(\gamma) = \bigotimes_s \mathrm{Sym}^n(\gamma_{T,s})$, a square matrix over $\mathcal{O}$ indexed by $\mathrm{Mon}^L_{k,n}$, multiplicative in γ.

(d) For natural numbers k, $\mathfrak{t}$ and an index i, $\tau_{k,\mathfrak{t}}(i)$ is 0 if $i < \mathfrak{t}$ and 1 otherwise. The labelling $\tau_{k,\mathfrak{t}}(\cdot)$ has the two blocks $\{i < \mathfrak{t}\}$ and $\{i \geq \mathfrak{t}\}$.

LEAN TwistingData.letterMatrix · TwistingData.polyAction · TwistingData.letterRep · twoBlock

Definition 2.4 (deep variables and depth)**.** In Setting 2.2, let $\mathfrak{t}$ and n be natural numbers. For a variable $v = (i, s)$ put $\mathrm{dp}_{T,\mathfrak{t}}(v) = 1$ if s is even and $i \geq \mathfrak{t}$, or s is odd and $i < \mathfrak{t}$, and $\mathrm{dp}_{T,\mathfrak{t}}(v) = 0$ otherwise; in the first case v is *deep* for $\mathfrak{t}$. For a family β in $\mathrm{Mon}^L_{k,n}$, its *depth* is

$$\mathrm{depth}^{k,n}_{T,\mathfrak{t}}(\beta) = \sum_{v=(i,s)} \beta_s(i)\, \mathrm{dp}_{T,\mathfrak{t}}(v) = \langle \mathrm{dp}_{T,\mathfrak{t}}(\cdot), \beta \rangle,$$

the degree of x^β in the deep variables. (A reading of the formal text by program gives the depth a sixth argument: it takes the name under which the degree is passed on for a further one.)

LEAN TwistingData.deepIndicator · TwistingData.depth

The scaling of the Hecke operator is the diagonal matrix $\mathrm{diag}(p^{\mathrm{depth}^{k,n}_{T,\mathfrak{t}}(\beta)})_\beta$. It is the action on forms of the diagonal matrix with entries 1 at the indices $i < \mathfrak{t}$ and p at

the others, read through the letters: directly at the even ones, and by the inverse transpose, up to the scalar p, at the odd ones.

Definition 2.5 (root variables and excess)**.** In Setting 2.2, let i_0, i_1 be indices and s, s_0 letters. The *root variable* is

$$\mathrm{rt}_{T,s}(i_0,i_1)=(i_1,s)\ \text{ if } s \text{ is even}, \qquad \mathrm{rt}_{T,s}(i_0,i_1)=(i_0,s)\ \text{ if } s \text{ is odd}.$$

For a letter s let $[s-s_0]$ be the representative of $s-s_0$ in $\{0,\dots,L-1\}$. The *excess weight* at s_0 is the real function on the variables $v=(i,s)$ given by

$$\mathrm{ex}^{i_0,i_1}_{T,s_0}(v)=\frac{1}{q_T}\Big([v=\mathrm{rt}_{T,s}(i_0,i_1)]\cdot P_T^{1+[s-1-s_0]}-[v=\mathrm{rt}_{T,s}(i_1,i_0)]\cdot P_T^{[s-s_0]}\Big),$$

where a bracket around a statement is 1 if it holds and 0 if not. The *excess* of an exponent α at s_0 is $\langle \mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot),\alpha\rangle$.

LEAN `TwistingData.rootVar` · `TwistingData.excessWeight`

Since $1+[s-1-s_0]$ is L for $s=s_0$ and $[s-s_0]$ otherwise, the excess of α at s_0 is, for $i_0\neq i_1$ and with $\alpha^+_s=\alpha(\mathrm{rt}_{T,s}(i_0,i_1))$ and $\alpha^-_s=\alpha(\mathrm{rt}_{T,s}(i_1,i_0))$,

$$\langle \mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot),\alpha\rangle=\alpha^+_{s_0}-\frac{\alpha^-_{s_0}}{q_T}+\sum_{s\neq s_0}\frac{P_T^{[s-s_0]}}{q_T}\,(\alpha^+_s-\alpha^-_s). \tag{1}$$

The two root variables of a letter are the two variables that the elementary matrix $1+vE_{i_0i_1}$, with v in W, couples at that letter; here $E_{ii'}$ is the matrix with the entry 1 at (i,i') and 0 elsewhere. In words: at an even letter it adds a multiple of $x_{i_0,s}$ to $x_{i_1,s}$, at an odd letter a multiple of $x_{i_1,s}$ to $x_{i_0,s}$.

Definition 2.6 (conditions on forms)**.** In Setting 2.2, let n be a natural number.

(a) For a labelling τ, an ideal I of $\mathcal{O}$ and a subset $\mathcal{B}$ of $\mathrm{Mon}^L_{k,n}$, $\mathrm{Tr}_{T,n}(\tau;I,\mathcal{B})$ is the $\mathcal{O}$-submodule of the forms F in $\mathcal{O}^{\mathrm{Mon}^L_{k,n}}$ such that $(\rho_{T,n}(\gamma)F)(\beta)\in I$ for every γ in $\mathrm{Lev}_\tau(W)$ and every β in $\mathcal{B}$.

(b) For indices i_0, i_1, an ideal I of $\mathcal{O}$ and a real number h,

$$\mathrm{Ex}^{i_0,i_1}_{T,n}(I;h)=\mathrm{Tr}_{T,n}(\tau_{k,i_1}(\cdot);I,\mathcal{B}),\qquad \text{where}$$
$$\mathcal{B}=\{\beta:\ h<\langle \mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot),\beta\rangle \text{ for some letter } s_0\}.$$

(c) For natural numbers k, $\mathfrak{t}$ and j, $\mathrm{Dp}^{k,n}_{T,\mathfrak{t}}(j)=\mathrm{Tr}_{T,n}(0;0,\{\beta:\mathrm{depth}^{k,n}_{T,\mathfrak{t}}(\beta)<j\})$, with the constant labelling 0 and the zero ideal.

LEAN `TwistingData.translatesIn` · `TwistingData.excessCond` · `TwistingData.deepForms`

So F lies in $\mathrm{Ex}^{i_0,i_1}_{T,n}(I;h)$ when, for every γ that is block diagonal with the blocks $\{i<i_1\}$ and $\{i\geq i_1\}$, the form $\rho_{T,n}(\gamma)F$ has modulo I only monomials whose excess is at most h at every letter; and F lies in $\mathrm{Dp}^{k,n}_{T,\mathfrak{t}}(j)$ when every translate of F under $\mathrm{GL}_k(W)$ has only monomials of depth at least j.

Definition 2.7 (filtrations)**.** Let $\mathcal{O}$ be a ring.

(a) Let $\mathcal{F}=(\mathcal{F}(\theta))_{\theta\in\mathbb{R}}$ be a family of additive subgroups of $\mathcal{O}$. We say that $\mathcal{F}$ is a real filtration if $1\in\mathcal{F}(0)$, if $\mathcal{F}(\theta)\cdot\mathcal{F}(\theta')\subseteq\mathcal{F}(\theta+\theta')$ for all θ,θ', and if $\mathcal{F}(\theta')\subseteq\mathcal{F}(\theta)$ whenever $\theta\leq\theta'$.

(b) For ϖ in $\mathcal{O}$ and a real number θ, $\mathrm{ad}_{\varpi}(\theta)$ is the additive group of the elements of $\mathcal{O}$ divisible by $\varpi^{\max(\lceil\theta\rceil,0)}$.

(c) For a family $\mathcal{F}$ of additive subgroups of $\mathcal{O}$, a set $\mathcal{V}$ of variables, a weight ω on $\mathcal{V}$ and a real number θ, $\mathrm{Gs}_{\mathcal{F},\omega}(\theta)$ is the additive group of the polynomials in $\mathcal{O}[x_{\mathcal{V}}]$ whose coefficient at each x^{α} lies in $\mathcal{F}(\theta-\langle\omega,\alpha\rangle)$.

LEAN `IsRealFiltration` · `adicFiltration` · `gaussFiltration`

In the sense of (a), $\mathrm{ad}_{\varpi}(\cdot)$ is a real filtration, because $\lceil\theta+\theta'\rceil\le\lceil\theta\rceil+\lceil\theta'\rceil$; and if $\mathcal{F}$ is a real filtration, then $\mathrm{Gs}_{\mathcal{F},\omega}(\cdot)$ is a real filtration, on the polynomial ring, because the coefficient of x^{α} in a product is a sum of products of coefficients at exponents with sum α. These are the two instances of the unit (§11, note 1). In $\mathrm{Gs}_{\mathrm{ad}_{\varpi}(\cdot),\omega}(\theta)$ a variable x_v sits at level $\omega(v)$: the level of a polynomial is the least value of *valuation plus weight* over its terms. For $\varpi=0$ the group $\mathrm{ad}_0(\theta)$ is $\mathcal{O}$ for $\theta\le 0$ and 0 for $\theta>0$.

Definition 2.8 (cones and slabs)**.** Let $k\ge 0$, $L\ge 1$, let par be a map from $\mathbb{Z}/L$ to the signs, ϱ a real number, and $\sigma=(\sigma_s)_{s\in\mathbb{Z}/L}$ permutations of the indices.

(a) $\mathrm{St}_{\mathrm{par},\varrho,\sigma}$ is the linear endomorphism of $\mathbb{R}^{k\times L}$ sending ξ to the vector with the coordinates $\mathrm{par}(s)\cdot\big(\varrho\,\xi(i,s+1)-\xi(\sigma_s(i),s)\big)$ at (i,s). For the identity permutations we write $\mathrm{St}_{\mathrm{par},\varrho,1}$.

(b) For reals $\delta=(\delta_s)_s$, $\mathrm{Sl}_k(\delta)$ is the set of the η in $\mathbb{R}^{k\times L}$ with all coordinates ≥ 0 and $\delta_s-1\le\sum_i\eta(i,s)\le\delta_s$ for every letter s.

(c) $\mathrm{Pc}_{\mathrm{par},\varrho}$ is the set of the ξ in $\mathbb{R}^{k\times L}$ such that for every letter s and all indices i, $i+1$: $\varrho\,\xi(i+1,s+1)\le\xi(i,s)$ if $\mathrm{par}(s)=+$, and $\xi(i+1,s)\le\varrho\,\xi(i,s+1)$ if $\mathrm{par}(s)=-$.

(d) In Setting 2.2 with $\mathcal{O}$ a field, for an index i_1 and a real number h, $\mathrm{Ec}_T(i_1;h)$ is the set of the η in $\mathbb{R}^{k\times L}$ such that for every letter s_0 and all indices i, $i+1$: $\langle\mathrm{ex}^{i,i+1}_{T,s_0}(\cdot),\eta\rangle\le h$ if $i+1=i_1$, and $\langle\mathrm{ex}^{i,i+1}_{T,s_0}(\cdot),\eta\rangle\le 0$ otherwise.

LEAN `permStep` · `slab` · `pieriCone` · `TwistingData.excessCone`

With $\eta=\mathrm{St}_{\mathrm{par},\varrho,1}(\xi)$, the condition of (c) at an even letter, together with $\eta(i,s)>0$, reads $\varrho\,\xi(i,s+1)>\xi(i,s)\ge\varrho\,\xi(i+1,s+1)$: the column $\xi(\cdot,s)$ interlaces the column $\varrho\,\xi(\cdot,s+1)$ from below. At an odd letter the roles are exchanged. Hence the name: a cone of cyclically interlacing columns.

Definition 2.9 (the size conditions)**.** For natural numbers P, o, L, k, n, $\mathfrak{t}$, λ and real numbers κ, y, z we write $\mathrm{Sz}(P,o,L,k,n,\mathfrak{t};\lambda,\kappa,y,z)$ for the conjunction of the ten conditions

$$0<\mathfrak{t},\quad 2\mathfrak{t}\le k,\quad \kappa\le 1,\quad 1\le y,\quad \lambda+\lambda=L,\quad L\,n\,k\,(\lambda+2)+n+k<P^{\lambda},$$
$$6\big(2(k+k^2)\,oL\cdot L+2\big)+2\le y,\qquad \frac{2(L+2)k}{y}\le\kappa,$$
$$\big(y+L(k+1)\big)\,k\,P^{3\mathfrak{t}}+k+2\le\frac{n}{y},\qquad L\,n\left(\frac{1}{P^{2\mathfrak{t}}}+\frac{\mathfrak{t}^2}{kP}\right)\le z.$$

LEAN `HeckeSizes` · in the formal text the ten arguments are called P, d, N, k, n, r, ℓ, κ, y, z

Definition 2.10 (Frobenius operators and conjugations)**.** In Setting 2.2, let $\mathfrak{t}$, λ, n, j be natural numbers, s a letter, γ an element of $\mathrm{GL}_k(W)$, and i_0, i_1, i indices.

(a) The *generic variables* are $x_{s,i,i'}$, for a letter and two indices; $X_s = (x_{s,i,i'})_{i,i'}$ is the generic matrix of the letter s. $X_T^{\mathrm{Fr}}(s,j)$ is the matrix over the polynomial ring in the generic variables over $\mathcal{O}$ whose (i,i') entry is $x_{s-j,i,i'}^{P_T^j}$: the generic matrix of the letter $s-j$ with its entries raised to the power P_T^j.

(b) Let $\mathcal{R}$ be a ring and $\psi = (\psi(s,j))$ matrices in $\mathrm{M}_k(\mathcal{R})$, for s a letter and j a natural number. For a letter s and a natural number m put $\Pi_s^m = \psi(s,m-1)\cdots\psi(s,1)\,\psi(s,0)$, and let B_s be the matrix in $\mathrm{M}_k(\mathcal{R})$ whose row i is row i of Π_s^m if s is even, and of the transpose of the adjugate of Π_s^m if s is odd, where $m = \lambda + \mathrm{dp}_{T,\mathrm{t}}((i,s))$. Then

$$\mathrm{Fr}_{T,\mathrm{t},\lambda,n}(\psi) = \bigotimes_s \mathrm{Sym}^n(B_s),$$

a square matrix over $\mathcal{R}$ indexed by $\mathrm{Mon}_{k,n}^L$.

(c) $\mathrm{cj}_{T,\gamma,s}$ is the multiplicative map $G \mapsto \iota_s(\gamma)\,G\,\iota_s(\gamma^{-1})$ of $\mathrm{M}_k(\mathcal{O})$.

(d) $\mathrm{iw}_{T,\lambda}^{i_0,i_1}(i) = ([i=i_1]-[i=i_0])/P_T^\lambda$, a real number.

(e) For a ring homomorphism $\chi\colon W \to \mathcal{O}$, $\mathrm{cs}_\chi(\gamma)$ is the endomorphism of the $\mathcal{O}$-algebra of polynomials in the entries $x_{i,i'}$ of one generic matrix X that substitutes the entries of $\chi(\gamma^{-1})\,X\,\chi(\gamma)$ for those of X.

LEAN `TwistingData.frobGenericMatrix` · `TwistingData.frobOperator` · `TwistingData.letterConj` · `TwistingData.indexWeight` · `ClassMean.conjSubst`

If the generic matrix of every letter s is specialised to $\iota_s(\gamma)$, for one γ in $\mathrm{GL}_k(W)$, then $X_T^{\mathrm{Fr}}(s,j)$ becomes congruent to $\iota_s(\gamma)$ modulo p, and the matrices B_s of (b), for $\psi = X_T^{\mathrm{Fr}}(\cdot,\cdot)$, become congruent to matrices whose rows are rows of $\iota_s(\gamma)^\lambda$ or of $\iota_s(\gamma)^{\lambda+1}$ (for odd letters, of their transposed adjugates). The operator on generic matrices keeps more: the exponents of the generic variables of each letter.

Inputs from other units. The results below are taken for granted in this note.

Input 1 (index divisibility; unit 149). *Let $\mathcal{O}$ be a commutative ring, V and V' modules over $\mathcal{O}$, let M_1, M_2, M_3 be submodules of V and M_1', M_2' submodules of V', and let π, π', π_0 be elements of $\mathcal{O}$. One writes $[M_1 : M_2] \mid \pi$, the index of M_2 in M_1 divides π, if for every natural number n' and every family of n' elements of M_1 there is a square matrix of size n' over $\mathcal{O}$ whose determinant divides π and whose rows, used as coefficients of combinations of the family, give n' elements of M_2. For an element p of $\mathcal{O}$, a natural number e, an $\mathcal{O}$-linear endomorphism Y of V and a real number θ one says that Y has type at most θ at p^e on M_1 if $Y(M_1) \subseteq M_1$ and $[M_1 : Y(M_1) + p^e M_1] \mid p^l$ for some natural number $l \leq \theta$. Then:*

(a) *if $\mathcal{O}$ is a valuation domain, $\mathcal{J}$ a finite set, G a square matrix over $\mathcal{O}$ indexed by $\mathcal{J}$ whose determinant divides π, and M_2 a submodule of $\mathcal{O}^{\mathcal{J}}$ that contains $G(\mathcal{O}^{\mathcal{J}})$, then $[\mathcal{O}^{\mathcal{J}} : M_2] \mid \pi$;*

(b) *if $[M_1 : M_2] \mid \pi$ and $[M_2 : M_3] \mid \pi'$, then $[M_1 : M_3] \mid \pi\pi'$;*

(c) *if $\Psi : V \to V'$ is an $\mathcal{O}$-linear map, $[M_1 : M_2] \mid \pi$, $M_1' \subseteq \Psi(M_1) + M_2'$ and $\Psi(M_2) \subseteq M_2'$, then $[M_1' : M_2'] \mid \pi$;*

(d) *if $Y : V \to V$ is an $\mathcal{O}$-linear map with $Y(M_1) \subseteq M_1$, if $[M_1 : Y(M_1) + \pi_0 M_1] \mid \pi$ and $[M_1 : M_2 + \pi_0 M_1] \mid \pi'$, then $[M_1 : Y(M_2) + \pi_0 M_1] \mid \pi\pi'$.*

Input 2 (normal forms over a valuation ring; units 120 and 112, background). *Let $\mathcal{A}$ be a commutative ring and $\mathcal{R}$ a subring such that $(\mathcal{A}, \mathcal{R})$ is a valuation pair: for any two elements of $\mathcal{A}$ there is an idempotent of $\mathcal{R}$ such that the $\mathcal{R}$-module spanned by the two elements lies in the $\mathcal{R}$-multiples of the first element minus the idempotent times the difference of the first and the second. If $\mathcal{A}$ is a valuation domain, then $(\mathcal{A}, \mathcal{A})$ is a valuation pair. Let $\mathcal{N}$ be a finite set.*

(a) (Hermite) *Let $\mathcal{K}$ be a finite set with an injective map to $\mathcal{N}$, by which $\mathcal{K}$ is regarded as a subset of $\mathcal{N}$, let X be a matrix over $\mathcal{A}$ with rows indexed by $\mathcal{N}$ and columns by $\mathcal{K}$, and let weights, natural numbers, be given on $\mathcal{K}$. Then there are an invertible matrix U over $\mathcal{A}$ indexed by $\mathcal{N}$, with the entries of U and of U^{-1} in $\mathcal{R}$, and a square matrix Δ over $\mathcal{A}$ indexed by $\mathcal{K}$, whose entry at (l, l') vanishes whenever the weight of l' is less than that of l, such that $X = U_{\cdot,\mathcal{K}}\, \Delta$ and $(U^{-1})_{\mathcal{K},\cdot}\, X = \Delta$; here $U_{\cdot,\mathcal{K}}$ consists of the columns of U in $\mathcal{K}$ and $(U^{-1})_{\mathcal{K},\cdot}$ of the rows of U^{-1} in $\mathcal{K}$.*

(b) (Smith) *Every square matrix X over $\mathcal{A}$ indexed by $\mathcal{N}$ is a product $U \operatorname{diag}(\varepsilon_l)_{l \in \mathcal{N}} U'$ with U, U' invertible, the entries of U, U^{-1}, U', U'^{-1} in $\mathcal{R}$, and ε_l in $\mathcal{A}$.*

(The reading of the Hermite form by program also lists a ring with involution, from an earlier part of its file; the statement does not involve it.)

LEAN `IndexDvd` · `HasType` · `IndexDvd.of_det_dvd` · `IndexDvd.trans` · `IndexDvd.map` · `IndexDvd.comp` · `IsValuationPair.hermite` · `IsValuationPair.smith_normal_form` · `isValuationPair_top`

Input 3 (a combinatorial Nullstellensatz with multiplicity; unit 57, background). *Let $\mathbb{F}$ be a field, $\mathcal{V}$ and $\mathcal{S}$ finite sets, and $\varkappa$ a map from $\mathcal{V}$ to the natural numbers with $0 < \varkappa(v)$ for every v; the* cost *of an exponent α' on $\mathcal{V}$ is $\sum_v \alpha'(v)/\varkappa(v)$. Let $(\upsilon_{\mathfrak{s}})_{\mathfrak{s}\in\mathcal{S}}$ be pairwise distinct points of $\mathbb{F}^{\mathcal{V}}$ with $\prod_v \varkappa(v) \leq \#\mathcal{S}$. Suppose that for every v in $\mathcal{V}$ there is a polynomial Φ_v in $\mathbb{F}[x_{\mathcal{V}}]$, all of whose monomials $x^{\alpha'}$ have cost less than 1, with $\Phi_v(\upsilon_{\mathfrak{s}}) = \upsilon_{\mathfrak{s}}(v)^{\varkappa(v)}$ for every $\mathfrak{s}$. Let j be a natural number and Φ a nonzero polynomial in $\mathbb{F}[x_{\mathcal{V}}]$ that lies, for every $\mathfrak{s}$, in the j-th power of the ideal of the polynomials vanishing at $\upsilon_{\mathfrak{s}}$. Then Φ has a monomial x^{α}, with nonzero coefficient, of cost at least j.* (The reading by program also lists a polynomial and an exponent of an earlier part of the file; they are the bound objects Φ_v and x^{α} of the statement.)

Input 4 (the order of the general linear group; unit 24, background). *For a finite field $\mathbb{F}$ and a finite set of k' elements, the group of the invertible matrices over $\mathbb{F}$ indexed by the set has $\prod_{l=0}^{k'-1}(\#\mathbb{F})^{l}((\#\mathbb{F})^{l+1}-1)$ elements; the formal text states this as an equation in an arbitrary field.*

LEAN `exists_le_cost_of_vanishing` · `card_GL_eq_prod`

Input 1 is the subject of the note on unit 149 of this write-up; there the definitions are stated with their arguments in the formal order and the four properties are proved. Input 2(a) is also an input of that note (its Input 4), where it is not proved either, and the fact that a valuation domain gives a valuation pair has a proof of two lines there; Input 2(b), the Smith form, comes from unit 112. The background library also supplies the vocabulary of the conventions (linear substitutions, symmetric powers, Kronecker products, Levi and parahoric subgroups; units 57 and 112).

References for the Inputs. The catalogue of quoted results of this write-up lists the Hermite form as an elementary lemma with no confirmed place in the literature; it has no entry yet for the Smith form, for Input 3 or for Input 4. What can be said of each:

- *Input 2.* This note uses both forms only for a valuation domain $\mathcal{O}$ and the pair $(\mathcal{O},\mathcal{O})$ (Propositions 9.2 and 9.3). There they are classical: among the entries of a nonzero matrix over a valuation domain one divides all the others, and operations on rows and columns move it to a corner and clear its row and its column. The rings over which every matrix has a triangular or a diagonal reduction are the subject of I. Kaplansky, *Elementary divisors and modules*, Trans. Amer. Math. Soc. 66 (1949), 464–491, and valuation rings are among them; the place in that paper was not confirmed. For the form with a valuation pair, which the artifact needs elsewhere: *reference to be confirmed.*
- *Input 3.* The artifact calls it a known result, a combinatorial Nullstellensatz with multiplicity (a nonzero polynomial that vanishes to high order on a large grid-like set of points has a term of large cost), and the header of its file names as sources N. Alon, *Combinatorial Nullstellensatz*, Combin. Probab. Comput. 8 (1999), 7–29, and S. Ball and O. Serra, *Punctured combinatorial Nullstellensätze*, Combinatorica 29 (2009), 511–522. Those papers concern the zeros of a polynomial on a product of finite subsets of the field, the second with multiplicity. Input 3 replaces the product by any set of points on which each power $x_v^{\varkappa(v)}$ agrees with a polynomial

of cost less than 1; this note did not compare the statements, and for the form stated here: *reference to be confirmed.*

- *Input 4* is classical, and its proof is one line: the column of index l of an invertible matrix, $l = 0, \dots, k' - 1$, is any vector outside the span of the l columns before it, so there are $\prod_{l=0}^{k'-1} ((\#\mathbb{F})^{k'} - (\#\mathbb{F})^{l})$ invertible matrices, which is the product of Input 4. A place in a textbook: *reference to be confirmed.*

3 First properties

Lemma 3.1 (elementary properties)**.** *In Setting 2.2:*

(a) *for every natural number j, every letter s and every v in W, p divides $\iota_{s+j}(v) - \iota_s(v)^{P_T^j}$;*
(b) *for γ in $\mathrm{GL}_k(W)$ and a variable $v = (i', s)$, $[\gamma]_T x_v = \sum_i (\gamma_{T,s})_{ii'} \, x_{i,s}$;*
(c) *for a natural number n, γ in $\mathrm{GL}_k(W)$ and a form F in $\mathcal{O}^{\mathrm{Mon}_{k,n}^L}$, $[\gamma]_T$ sends the polynomial $\sum_\beta F(\beta) x^\beta$ to the polynomial of the form $\rho_{T,n}(\gamma)F$;*
(d) *for a ring homomorphism $\chi \colon \mathcal{O} \to \mathcal{O}'$, a natural number n and γ in $\mathrm{GL}_k(W)$, the matrix $\rho_{\chi_* T, n}(\gamma)$ is obtained by applying χ to the entries of $\rho_{T,n}(\gamma)$;*
(e) *for natural numbers n, $\mathfrak{t}$ and an element π of $\mathcal{O}$, the diagonal matrix with the entries $\pi^{\mathrm{depth}_{T,\mathfrak{t}}^{k,n}(\beta)}$, $\beta \in \mathrm{Mon}_{k,n}^L$, equals $\bigotimes_s \mathrm{Sym}^n(\mathrm{diag}(\pi^{\mathrm{dp}_{T,\mathfrak{t}}((i,s))})_i)$.*

Moreover $1 < P_T$ and $1 < q_T$; the residue field of W is finite; and $\varpi \neq 0$ if $\mathcal{O}$ has characteristic zero.

Proof. (a) By induction on j: if $\iota_{s+j}(v) \equiv \iota_s(v)^{P_T^j}$ modulo p, then, modulo p,

$$\iota_{s+j+1}(v) \equiv \iota_{s+j}(v)^{P_T} \equiv \iota_s(v)^{P_T^{j+1}},$$

because congruent elements have congruent powers. (b) is the definition of the linear substitution. (c) By (b) and the definition of Sym^n, $[\gamma]_T$ sends the monomial $\prod_s x^{\beta_s}$, with x^{β_s} in the variables of the letter s, to

$$\prod_s \sum_{\beta'_s} \mathrm{Sym}^n(\gamma_{T,s})_{\beta'_s, \beta_s} x^{\beta'_s} = \sum_{\beta'} \rho_{T,n}(\gamma)_{\beta', \beta} \, x^{\beta'}.$$

(d) The entries of $\mathrm{Sym}^n(G)$ are polynomials with integer coefficients in the entries of G. (e) The linear substitution of a diagonal matrix multiplies each monomial by the product of the diagonal entries to the powers of the exponent. The last assertions: $P_T \geq 5$; $\#\mathbb{F}_W = q_T$ is a positive natural number; and $\varpi^2 = p \neq 0$. □

LEAN `TwistingData.frobenius_pow_congr` · `TwistingData.polyAction_X` · `TwistingData.polyAction_polyOfCoeffs` · `TwistingData.letterRep_map` · `TwistingData.diagonal_pow_depth` · `TwistingData.one_lt_P` · `TwistingData.one_lt_q` · `TwistingData.finite_residueField` · `TwistingData.w_ne_zero`

Lemma 3.2 (entries of parahoric elements)**.** *In Setting 2.2, let τ be a labelling, γ an element of $\mathrm{Par}_\tau(W)$, s a letter, and i, i' indices such that $\tau(i) < \tau(i')$ if s is even and $\tau(i') < \tau(i)$ if s is odd. Then p divides the entry $(\gamma_{T,s})_{ii'}$ in $\mathcal{O}$.*

Proof. Let v be the (i, i') entry of γ if s is even and of $(\gamma^{-1})^{\mathsf{T}}$ if s is odd, so that the entry in question is $\iota_s(v)$. In both cases v lies in $\mathfrak{m}_W$: for even s by the definition of the parahoric subgroup, for odd s because γ^{-1} lies in it and $v = (\gamma^{-1})_{i'i}$. Hence $1 - v^{q_T - 1}$

is a unit of W and its image under ι_s a unit of $\mathcal{O}$. By Lemma 3.1(a) with $j = L$, where $s + L = s$ and $P_T^L = q_T$, the prime p divides $\iota_s(v) - \iota_s(v)^{q_T} = \iota_s(v) \cdot \iota_s(1 - v^{q_T - 1})$, hence $\iota_s(v)$. □

LEAN TwistingData.p_dvd_letterMatrix_of_mem_parahoric

Lemma 3.3 (size of the excess weights)**.** *In Setting 2.2, for a letter s_0, indices i_0, i_1 and a variable v: $-\frac{1}{5} \le \mathrm{ex}_{T,s_0}^{i_0,i_1}(v) \le 1$.*

Proof. Let $v = (i, s)$. As $[s - s_0] \le L - 1$ and $P_T \ge 5$,

$$5\, P_T^{[s-s_0]} \le q_T;$$

and $1 + [s - 1 - s_0]$ is L if $s = s_0$ and $[s - s_0]$ otherwise. So the first term of the definition is 0, or 1, or lies in $(0, \frac{1}{5}]$, and the second is 0 or lies in $[-\frac{1}{5}, 0)$. □

LEAN TwistingData.excessWeight_mem_Icc · TwistingData.one_add_val_sub_one_sub · TwistingData.five_mul_P_pow_le_q

Lemma 3.4 (half of the letters are deep)**.** *In Setting 2.2, let $\mathfrak{t}$ be a natural number and i an index. Then $\sum_s \mathrm{dp}_{T,\mathfrak{t}}((i, s)) = L/2$. (The formal statement asks that $\mathcal{O}$ be a field and does not use it; it writes the quotient of natural numbers.)*

Proof. The parity alternates, so $\mathrm{dp}_{T,\mathfrak{t}}((i, s)) + \mathrm{dp}_{T,\mathfrak{t}}((i, s + 1)) = 1$ for every letter; summing over the letters gives twice the sum on the left and L on the right. □

LEAN TwistingData.sum_deepIndicator

4 The root lemma

Lemma 4.1 (a count of zeros against degree)**.** *Let W be a local ring, $\mathcal{O}$ a ring, $\chi\colon W \to \mathcal{O}$ a ring homomorphism, Φ a nonzero polynomial in one variable X over $\mathcal{O}$, and e a natural number. Suppose that $(X - \chi(v))^e$ divides Φ for every v in W; equivalently, X^e divides $\Phi(X + \chi(v))$. Then $e \cdot \#\mathbb{F}_W \le \deg \Phi$.*

Proof. If $\mathbb{F}_W$ is infinite the count on the left is 0. Otherwise choose one element of W in each residue class. The difference of two of them is a unit of W, so its image is a unit of $\mathcal{O}$, and the polynomials $(X - \chi(v))^e$ for the chosen v are pairwise coprime. Each divides Φ; so does their product, which is monic of degree $e \cdot \#\mathbb{F}_W$. A nonzero polynomial is not divisible by a monic polynomial of larger degree. □

LEAN stepanov_count

Lemma 4.2 (filtrations under substitution)**.** *Let $\mathcal{O}$ be a ring, $\mathcal{A}$ a commutative $\mathcal{O}$-algebra, $\mathcal{V}$ a set of variables, $\mathcal{F} = (\mathcal{F}(\theta))_\theta$ a family of additive subgroups of $\mathcal{O}$, ω a weight on $\mathcal{V}$ and θ a real number. Let χ and χ' be homomorphisms of $\mathcal{O}$-algebras from $\mathcal{O}[x_\mathcal{V}]$ to $\mathcal{A}$, and let $\mathcal{G} = (\mathcal{G}(\theta))_\theta$ be a family of additive subgroups of $\mathcal{A}$ such that $\mathcal{G}$ is a real filtration. Let Φ be a polynomial in $\mathrm{Gs}_{\mathcal{F},\omega}(\theta)$. Suppose that*

(i) *$\chi(x_v) \in \mathcal{G}(\omega(v))$ for every v in $\mathcal{V}$;*
(ii) *$\chi'(x_v) - \chi(x_v) \in \mathcal{G}(\omega(v) + \frac{1}{20})$ for every v in $\mathcal{V}$;*
(iii) *the image in $\mathcal{A}$ of every element of $\mathcal{F}(\theta')$ lies in $\mathcal{G}(\theta')$, for every real θ'.*

Then $\chi'(\Phi) \in \mathcal{G}(\theta)$ and $\chi'(\Phi) - \chi(\Phi) \in \mathcal{G}(\theta + \frac{1}{20})$.

Proof. It suffices to treat one term πx^α with π in $\mathcal{F}(\theta - \langle\omega, \alpha\rangle)$. By (i) and (ii) and since $\mathcal{G}$ is decreasing, $\chi'(x_v)$ and $\chi(x_v)$ lie in $\mathcal{G}(\omega(v))$; so $\chi'(x^\alpha)$ lies in $\mathcal{G}(\langle\omega, \alpha\rangle)$,

and with (iii) $\chi'(\pi x^\alpha)$ lies in $\mathcal{G}(\theta)$. The difference $\chi'(x^\alpha)-\chi(x^\alpha)$, expanded as a product of sums $\chi(x_v)+(\chi'(x_v)-\chi(x_v))$ less the product of the first summands, is a sum of products of $|\alpha|$ factors of which at least one is a difference; each such product lies in $\mathcal{G}(\langle\omega,\alpha\rangle+\frac{1}{20})$. □

LEAN `aeval_sub_mem_of_gaussFiltration` · used with it: `mem_adicFiltration_of_nonpos` (an element lies in $\mathrm{ad}_\varpi(\theta)$ if it is 0 or $\theta\le 0$), `monomial_mem_gaussFiltration` (a term πx^α with π in $\mathcal{F}(\theta-\langle\omega,\alpha\rangle)$ lies in $\mathrm{Gs}_{\mathcal{F},\omega}(\theta)$), `TwistingData.X_mem_gaussFiltration` ($x_v$ lies in $\mathrm{Gs}_{\mathrm{ad}_\varpi(\cdot),\omega}(\omega(v))$)

Proof of Theorem 1. Throughout, s runs over the letters, and we write

$$x_s^+=x_{\mathrm{rt}_{T,s}(i_0,i_1)},\qquad x_s^-=x_{\mathrm{rt}_{T,s}(i_1,i_0)},$$

and $\omega_s^\pm$, $\alpha_s'^\pm$ for the values of ω and of an exponent α' at these two variables. For every letter the two variables differ, as $i_0\neq i_1$. Put

$$\mathrm{w}^+(\alpha')=q_T\,\alpha_{s_0}'^+ +\sum_{s\neq s_0}P_T^{[s-s_0]}\alpha_s'^+,\qquad \mathrm{w}^-(\alpha')=q_T\,\alpha_{s_0}'^- +\sum_{s\neq s_0}q_T\,P_T^{[s-s_0]}\alpha_s'^-.$$

By (1), $q_T^2\cdot\langle \mathrm{ex}_{T,s_0}^{i_0,i_1}(\cdot),\alpha\rangle=q_T\,\mathrm{w}^+(\alpha)-\mathrm{w}^-(\alpha)$, so the claim is $q_T\,\mathrm{w}^+(\alpha)\le\mathrm{w}^-(\alpha)$. Put $\epsilon=(\omega_{s_0}^+-\omega_{s_0}^-)/q_T$; then $\epsilon>0$. The hypothesis on ω, with $P_T^{[s-s_0]}\ge 5$ and $5\,P_T^{[s-s_0]}\le q_T$ for $s\neq s_0$, gives for these letters

$$\epsilon\,q_T\,P_T^{[s-s_0]}\ \ge\ 2,\qquad \epsilon\,P_T^{[s-s_0]}\ \le\ 0.32,\qquad 0.4\le\omega_s^+-\omega_s^-\le 1.6. \tag{2}$$

Step 1: the elements of the Levi subgroup. For v in W let γ_v be the product of the permutation matrix that exchanges i_0 and i_1 with the elementary matrix $1\mp vE_{i_0i_1}$, the sign being $-$ if s_0 is even. It lies in $\mathrm{Lev}_\tau(W)$ because $\tau(i_0)=\tau(i_1)$. Let $\mathrm{sg}_s=-1$ if s has the parity of s_0 and $\mathrm{sg}_s=+1$ otherwise. A computation with Lemma 3.1(b), separately for even and odd letters, gives

$$[\gamma_v]_T x_s^+=x_s^-+\mathrm{sg}_s\,\iota_s(v)\,x_s^+,\qquad [\gamma_v]_T x_s^-=x_s^+, \tag{3}$$

and $[\gamma_v]_T$ fixes the other variables.

Step 2: two substitutions. Let $\mathcal{A}=\mathcal{O}[x_v][X]$, with one further variable X. Let χ_0 be the homomorphism of $\mathcal{O}$-algebras from $\mathcal{O}[x_v]$ to $\mathcal{A}$ with

$$\chi_0(x_{s_0}^+)=x_{s_0}^-,\qquad \chi_0(x_s^-)=x_s^-\,X^{\mathrm{w}^-(s)}\ \text{ for all } s,\qquad \chi_0(x_v)=x_v\ \text{ otherwise,}$$

where $\mathrm{w}^-(s)=q_T\,P_T^{[s-s_0]}$ is the coefficient of $\alpha_s'^-$ in $\mathrm{w}^-(\alpha')$; and let χ_1 agree with χ_0 except that, for $s\neq s_0$,

$$\chi_1(x_s^+)=x_s^+-\mathrm{sg}_s\,x_s^-,\qquad \chi_1(x_s^-)=x_s^-\,X^{\mathrm{w}^-(s)}-\mathrm{sg}_s\,x_s^+\,X^{P_T^{[s-s_0]}}.$$

For an exponent α' let α'^* be the exponent obtained by moving the value at $\mathrm{rt}_{T,s_0}(i_0,i_1)$ onto $\mathrm{rt}_{T,s_0}(i_1,i_0)$; then $\chi_0(x^{\alpha'})=x^{\alpha'^*}X^{\mathrm{w}^-(\alpha')}$.

On $\mathcal{A}$ consider two families of additive subgroups. An element lies in $\mathcal{G}_-(\theta)$, respectively in $\mathcal{G}_+(\theta)$, if its coefficient at each $x^{\alpha'}X^j$ is divisible by ϖ to the power

$$\begin{aligned}&\max(\lceil\theta-\langle\omega,\alpha'\rangle-\epsilon\,\mathrm{w}^-(\alpha')+\epsilon j\rceil,0) &&\text{for } \mathcal{G}_-(\theta),\\ &\max(\lceil\theta-\langle\omega,\alpha'\rangle+\epsilon\,\mathrm{w}^+(\alpha')-\epsilon j\rceil,0) &&\text{for } \mathcal{G}_+(\theta).\end{aligned}$$

Both are of the kind of Definition 2.7(c), with a weight on the variables x_v and X, so each has the three properties of Definition 2.7(a), and each contains the image of $\mathrm{ad}_\varpi(\theta)$ at level θ. Since $\epsilon q_T = \omega_{s_0}^+ - \omega_{s_0}^-$, moving the exponent does not change the two weights:

$$\langle \omega, \alpha'^* \rangle + \epsilon\, \mathrm{w}^-(\alpha'^*) = \langle \omega, \alpha' \rangle + \epsilon\, \mathrm{w}^-(\alpha'), \qquad \langle \omega, \alpha'^* \rangle - \epsilon\, \mathrm{w}^+(\alpha'^*) = \langle \omega, \alpha' \rangle - \epsilon\, \mathrm{w}^+(\alpha'). \tag{4}$$

Step 3: the degree. Put $\theta_0 = e + \langle \omega, \alpha \rangle$. We apply Lemma 4.2 to Φ, which lies in $\mathrm{Gs}_{\mathrm{ad}_{\varpi}(\cdot),\omega}(\theta_0)$ by the hypothesis for $\gamma = 1$, with $\chi = \chi_0$, $\chi' = \chi_1$ and $\mathcal{G} = \mathcal{G}_-$. A term $x_{v'} X^j$ lies in $\mathcal{G}_-(\theta)$ when $\theta \le \omega(v') + \epsilon(\mathrm{w}^-(v') - j)$, with $\mathrm{w}^-(v')$ the coefficient of v'. Condition (i) holds with equality in each case, for $x_{s_0}^+$ by the choice of ϵ. Condition (ii) concerns the letters $s \ne s_0$: for x_s^+ it reads $\omega_s^+ + \frac{1}{20} \le \omega_s^- + \epsilon\, q_T P_T^{[s-s_0]}$, and for x_s^- it reads $\omega_s^- + \frac{1}{20} \le \omega_s^+ - \epsilon\, P_T^{[s-s_0]}$; both follow from (2). The lemma gives

$$\chi_1(\Phi) \in \mathcal{G}_-(\theta_0), \qquad \chi_1(\Phi) - \chi_0(\Phi) \in \mathcal{G}_-(\theta_0 + \tfrac{1}{20}). \tag{5}$$

Step 4: the zeros. Fix v in W, write $\pi = \iota_{s_0}(v)$, and let t_v be the automorphism $X \mapsto X + \pi$ of $\mathcal{A}$. By hypothesis the polynomial $\Phi_v = [\gamma_v^{-1}]_T \Phi$ lies in $\mathrm{Gs}_{\mathrm{ad}_{\varpi}(\cdot),\omega}(\theta_0)$, and $\mathrm{t}_v(\chi_1(\Phi)) = \chi_v(\Phi_v)$ for the homomorphism $\chi_v = \mathrm{t}_v \circ \chi_1 \circ [\gamma_v]_T$. We apply Lemma 4.2 with $\chi = \chi' = \chi_v$ and $\mathcal{G} = \mathcal{G}_+$, and have to check that $\chi_v(x_v)$ lies in $\mathcal{G}_+(\omega(v))$ for every variable. A term $\pi' x_{v'} X^j$ lies in $\mathcal{G}_+(\theta)$ when ϖ to the power $\max(\lceil \theta - \omega(v') + \epsilon(\mathrm{w}^+(v') - j) \rceil, 0)$ divides π', with $\mathrm{w}^+(v')$ the coefficient of v' in w^+. By Lemma 3.1(a), $\iota_s(v) \equiv \pi^{P_T^{[s-s_0]}}$ and $\pi^{q_T} \equiv \pi$ modulo p, and $(X+\pi)^{P_T^j} \equiv X^{P_T^j} + \pi^{P_T^j}$ modulo p because P_T is a power of p. From (3) and the definition of χ_1 one finds, with $P' = P_T^{[s-s_0]}$:

$$\begin{aligned}
\chi_v(x_{s_0}^+) &= x_{s_0}^-\big((X+\pi)^{q_T} - \pi\big) = x_{s_0}^-\big(X^{q_T} + p\,(\dots)\big), \qquad \chi_v(x_{s_0}^-) = x_{s_0}^-, \\
\chi_v(x_s^+) &= x_s^-\big((X+\pi)^{q_T P'} - \iota_s(v)\big) - \mathrm{sg}_s\, x_s^+\big((X+\pi)^{P'} - \iota_s(v)\big) \\
&= x_s^-\big(X^{q_T P'} + p\,(\dots)\big) - \mathrm{sg}_s\, x_s^+\big(X^{P'} + p\,(\dots)\big) \qquad (s \ne s_0), \\
\chi_v(x_s^-) &= x_s^+ - \mathrm{sg}_s\, x_s^- \qquad (s \ne s_0),
\end{aligned}$$

where the dots are polynomials in X of degree less than that of the leading power, and χ_v fixes the other variables. In the third line $\mathrm{sg}_s^2 = 1$ was used. Now each term is checked against the criterion. The leading terms: $x_{s_0}^- X^{q_T}$ is at level $\omega_{s_0}^- + \epsilon q_T = \omega_{s_0}^+$; $x_s^+ X^{P'}$ is at level ω_s^+; $x_s^- X^{q_T P'}$ is at level $\omega_s^- + \epsilon q_T P' \ge \omega_s^+$ by (2); x_s^+ is at level $\omega_s^+ - \epsilon P' \ge \omega_s^-$ by (2), and x_s^- and $x_{s_0}^-$ are at their own levels. The terms with the factor $p = \varpi^2$ need the power of ϖ to be at most 2: for $x_{s_0}^- X^j$ it is at most $\lceil \omega_{s_0}^+ - \omega_{s_0}^- \rceil \le 2$; for $x_s^- X^j$ at most $\lceil \omega_s^+ - \omega_s^- \rceil \le 2$; for $x_s^+ X^j$ with $j < P'$ at most $\lceil \epsilon P' \rceil \le 1$. So the lemma applies:

$$\mathrm{t}_v(\chi_1(\Phi)) \in \mathcal{G}_+(\theta_0) \qquad \text{for every } v \text{ in } W. \tag{6}$$

Step 5: the count. Let Φ^*, a polynomial in X over $\mathcal{O}$, be the coefficient of x^{α^*} in $\chi_1(\Phi)$. By (5) and (4) the coefficient of X^j in Φ^* is divisible by ϖ to the power $\lceil e + \epsilon(j - \mathrm{w}^-(\alpha)) \rceil$, which is at least $e+1$ for $j > \mathrm{w}^-(\alpha)$. By the second part of (5), the coefficient of $X^{\mathrm{w}^-(\alpha)}$ in Φ^* differs by a multiple of ϖ^{e+1} from the coefficient of $x^{\alpha^*} X^{\mathrm{w}^-(\alpha)}$ in $\chi_0(\Phi)$. A term $x^{\alpha'}$ of Φ contributes to the latter only if $\alpha'^* = \alpha^*$ and $\mathrm{w}^-(\alpha') = \mathrm{w}^-(\alpha)$; then α' and α agree outside the two root variables of s_0, have the

same sum there, and the same value at $\mathrm{rt}_{T,s_0}(i_1,i_0)$, so $\alpha'=\alpha$. Thus that coefficient is the coefficient of x^α in Φ, which ϖ^{e+1} does not divide. Finally, taking the coefficient of x^{α^*} commutes with t_υ, and by (6) and (4) the coefficient of X^j in $\Phi^*(X+\iota_{s_0}(\upsilon))$ is divisible by ϖ to the power $\lceil e+\epsilon(\mathrm{w}^+(\alpha)-j)\rceil \geq e+1$ for $j<\mathrm{w}^+(\alpha)$.

So the image of Φ^* in $(\mathcal{O}/\varpi^{e+1}\mathcal{O})[X]$ is not zero, has degree at most $\mathrm{w}^-(\alpha)$, and is divisible by $(X-\iota_{s_0}(\upsilon))^{\mathrm{w}^+(\alpha)}$ for every υ in W. Lemma 4.1, for the homomorphism from W to $\mathcal{O}/\varpi^{e+1}\mathcal{O}$ induced by ι_{s_0}, gives $\mathrm{w}^+(\alpha)\cdot\#\mathbb{F}_W\leq\mathrm{w}^-(\alpha)$, and $\#\mathbb{F}_W=q_T$. □

LEAN `TwistingData.root_lemma` · `stepanov_count` · `aeval_sub_mem_of_gaussFiltration`

5 The volume of the cyclic interlacing cone

Lemma 5.1 (the determinant of an interlacing pattern)**.** *Let $k\geq 0$, and let $\xi_0\geq\ldots\geq\xi_{k-1}$ and $\eta_0\geq\ldots\geq\eta_{k-1}$ be weakly decreasing sequences of real numbers. The determinant of the $k\times k$ matrix whose (i,i') entry is 1 if $\eta_{i'}<\xi_i$ and 0 otherwise equals 1 if $\eta_i<\xi_i$ for all i and $\xi_{i+1}\leq\eta_i$ for all $i<k-1$, and equals 0 otherwise.*

Proof. By induction on k; for $k=0$ both sides are 1. Let $k\geq 1$. If $\eta_0<\xi_i$ for some $i\geq 1$, then the rows 0 and i consist of ones, since $\eta_{i'}\leq\eta_0<\xi_i\leq\xi_0$; the determinant is 0, and the condition fails because $\xi_1\geq\xi_i>\eta_0$. Otherwise $\xi_i\leq\eta_0$ for all $i\geq 1$, column 0 has at most its entry in row 0 different from zero, and the determinant is that entry, 1 or 0 according as $\eta_0<\xi_0$ or not, times the determinant of the same kind for the sequences without their first members. The induction hypothesis evaluates the latter, and $\xi_1\leq\eta_0$ holds. □

LEAN `det_interlacing_indicator`

Proposition 5.2 (the volume as a signed sum)**.** *Let k and m be natural numbers and $L=m+1$, let ϱ be a real number with $1<\varrho$,* par *a map from $\mathbb{Z}/L$ to the signs, $\delta=(\delta_s)_s$ real numbers, and $\mathcal{C}$ a subset of $\mathbb{R}^{k\times L}$ such that, for every ξ: $\mathrm{St}_{\mathrm{par},\varrho,1}(\xi)\in\mathcal{C}$ if and only if $\xi\in\mathrm{Pc}_{\mathrm{par},\varrho}$. For a permutation σ' of the indices let σ'^* be the linear map $f\mapsto f\circ\sigma'$ of $\mathbb{R}^k$ and $\mathrm{dt}(\sigma')=|\det(1-\varrho^{-L}\sigma'^*)|$. Then*

$$\mathrm{vol}(\mathcal{C}\cap\mathrm{Sl}_k(\delta))=\frac{\mathrm{dt}(\mathrm{id})}{k!}\left(\sum_{\sigma'}\frac{\mathrm{sgn}(\sigma')}{\mathrm{dt}(\sigma')}\right)\mathrm{vol}(\mathrm{Sl}_k(\delta)),$$

the sum being over all permutations of the indices. (The formal statement is for the letters $0,\ldots,m$ with addition modulo $m+1$.)

Proof. For a tuple $\sigma=(\sigma_s)_s$ of permutations write $S_\sigma=\mathrm{St}_{\mathrm{par},\varrho,\sigma}$, and S_1 for the identity permutations. The set $\mathrm{Sl}_k(\delta)$ is bounded, and so is its intersection with any set; all volumes below are finite.

The determinant of S_σ. Up to the signs $\mathrm{par}(s)$, S_σ is $\varrho\cdot\mathrm{Sh}\circ(1-\mathrm{N})$, where $(\mathrm{Sh}\,\xi)(i,s)=\xi(i,s+1)$ and $(\mathrm{N}\xi)(\cdot,s)=N_s\,\xi(\cdot,s-1)$ with $N_s=\varrho^{-1}\sigma_{s-1}^*$. For such a cyclic operator,

$$\det(1-\mathrm{N})=\det(1-N_{L-1}\cdots N_1N_0).$$

Indeed, order the letters as $0,\ldots,L-1$ and let El be the operator with

$$(\mathrm{El}\eta')(\cdot,s)=\sum_{s'\leq s}N_sN_{s-1}\cdots N_{s'+1}\,\eta'(\cdot,s');$$

then

$$(\mathrm{El}(1-\mathrm{N})\xi)(\cdot,s)=\xi(\cdot,s)-N_s\cdots N_0\,\xi(\cdot,L-1).$$

The operator El has determinant 1, and $\mathrm{El}(1-\mathrm{N})$ is triangular with the diagonal blocks $1,\dots,1$ and $1-N_{L-1}\cdots N_0$. Hence

$$|\det S_\sigma| = \varrho^{kL}\cdot \mathrm{dt}(\sigma_0\sigma_1\cdots\sigma_{L-1}), \tag{7}$$

because $N_{L-1}\cdots N_0 = \varrho^{-L}(\sigma_{L-1}\sigma_0\cdots\sigma_{L-2})^*$ and dt takes the same value on conjugate permutations. As $\varrho>1$, the right side is not zero: $\mathrm{dt}(\sigma')$ is the product of the numbers $1-\varrho^{-Ll}$ over the cycles of σ', of lengths l.

Two families of sets. Let $\mathcal{W}$ be the set of the ξ such that the column sums $\sum_i (S_1\xi)(i,s)$ lie in $[\delta_s-1,\delta_s]$ for every letter. The column sums of $S_\sigma\xi$ are those of $S_1\xi$, the permutations only reordering the summands. For a tuple σ let $\mathcal{W}_\sigma$ be the set of the ξ in $\mathcal{W}$ with all coordinates of $S_\sigma\xi$ positive. It is the preimage under S_σ of the slab without its walls, which have measure zero, so by (7) $\mathrm{vol}(\mathcal{W}_\sigma) = \varrho^{-kL}\,\mathrm{dt}(\sigma_0\cdots\sigma_{L-1})^{-1}\,\mathrm{vol}(\mathrm{Sl}_k(\delta))$. Let Υ be the set of the ξ in $\mathrm{Pc}_{\mathrm{par},\varrho}$ with all coordinates of $S_1\xi$ positive. By the hypothesis on $\mathcal{C}$, $\mathcal{W}\cap\Upsilon$ is the preimage under S_1 of $\mathcal{C}\cap\mathrm{Sl}_k(\delta)$ without the walls, so $\mathrm{vol}(\mathcal{W}\cap\Upsilon) = \varrho^{-kL}\,\mathrm{dt}(\mathrm{id})^{-1}\,\mathrm{vol}(\mathcal{C}\cap\mathrm{Sl}_k(\delta))$. For a tuple $\tau' = (\tau'_s)_s$ of permutations let $\xi\circ\tau'$ be the vector with coordinates $\xi(\tau'_s(i),s)$; the map $\xi\mapsto\xi\circ\tau'$ preserves volume and maps $\mathcal{W}$ to itself.

A pointwise identity. We claim that for every ξ

$$\#\{\tau' :\ \xi\circ\tau'\in\Upsilon\} \;=\; \sum_\sigma \mathrm{sgn}(\sigma_0\cdots\sigma_{L-1})\cdot\big[\text{all coordinates of } S_\sigma\xi \text{ are positive}\big]. \tag{8}$$

The right side is the product over the letters s of

$$\sum_{\sigma_s}\mathrm{sgn}(\sigma_s)\prod_i\big[\mathrm{par}(s)\big(\varrho\,\xi(i,s+1)-\xi(\sigma_s(i),s)\big)>0\big],$$

that is, of the determinants of the matrices A_s whose entry at (i,i') is

$$\big[\mathrm{par}(s)\big(\varrho\,\xi(i,s+1)-\xi(i',s)\big)>0\big].$$

Reorder the rows of A_s so that $\xi(\cdot,s+1)$ becomes weakly decreasing, and its columns so that $\xi(\cdot,s)$ does. This multiplies $\det A_s$ by the signs of two permutations, and in the product over the circle of letters each sign occurs twice. After the reordering Lemma 5.1 applies, to the transposed matrix when $\mathrm{par}(s)=-$: the determinant is 1 if the decreasing rearrangements $\xi^\downarrow$ of the columns satisfy, for all i,

$$\begin{aligned}\varrho\,\xi^\downarrow(i,s+1) > \xi^\downarrow(i,s) \ge \varrho\,\xi^\downarrow(i+1,s+1) \qquad &\text{when } \mathrm{par}(s)=+,\\ \xi^\downarrow(i,s) > \varrho\,\xi^\downarrow(i,s+1) \ge \xi^\downarrow(i+1,s) \qquad &\text{when } \mathrm{par}(s)=-,\end{aligned}$$

and it is 0 otherwise. These are the conditions that define Υ, at the letter s. So the right side of (8) is 1 if $\xi^\downarrow\in\Upsilon$ and 0 otherwise. On the left, the columns of a vector in Υ are strictly decreasing, by the same inequalities; so $\xi\circ\tau'\in\Upsilon$ forces $\xi\circ\tau' = \xi^\downarrow$ and determines τ', the entries of each column being distinct. Hence the left side is also 1 if $\xi^\downarrow\in\Upsilon$ and 0 otherwise.

Integration. Integrate (8) over $\mathcal{W}$. The left side gives $(k!)^L\,\mathrm{vol}(\mathcal{W}\cap\Upsilon)$, the right side $\sum_\sigma \mathrm{sgn}(\sigma_0\cdots\sigma_{L-1})\,\mathrm{vol}(\mathcal{W}_\sigma)$. Each permutation σ' is the product $\sigma_0\cdots\sigma_{L-1}$ for $(k!)^{L-1}$ tuples. Inserting the two volumes and cancelling $\varrho^{-kL}(k!)^{L-1}$ gives the formula. □

LEAN `volume_inter_slab_eq_signed_sum` · `isBounded_inter_slab` (the intersection of any set with a slab is bounded)

Proof of Theorem 2. By Proposition 5.2, $\mathrm{vol}(\mathcal{C} \cap \mathrm{Sl}_k(\delta))$ is $\mathrm{vol}(\mathrm{Sl}_k(\delta))$ times a number that depends only on k and on $q = \varrho^L$. We evaluate this number in the case of one letter, $L = 1$, with the sign $+$, the real number q in the place of ϱ, $\delta = 1$ and $\mathcal{C} = \mathrm{Pc}_{+,q}$, the set of the ξ in $\mathbb{R}^k$ with $q\,\xi(i+1) \le \xi(i)$ for all i; the hypothesis holds because $S_1\xi = (q-1)\xi$ and $\mathcal{C}$ is a cone. Put $\mathrm{f}_l = (q^{l+1}-1)/(q-1)$ and let G be the linear endomorphism of $\mathbb{R}^k$ with $(G\xi)(l) = \mathrm{f}_l\,(\xi(l) - q\,\xi(l+1))$, where $\xi(k) = 0$. It is triangular with the diagonal entries f_l, so $\det G = \prod_{l=0}^{k-1} \mathrm{f}_l > 0$. It preserves the sum of the coordinates, because $\mathrm{f}_l - q\,\mathrm{f}_{l-1} = 1$. And $G\xi$ has all coordinates ≥ 0 if and only if $\xi(l) \ge q\,\xi(l+1)$ for all l, which implies $\xi \ge 0$ by descending induction. Hence the preimage of $\mathrm{Sl}_k(1)$ under G is $\mathcal{C} \cap \mathrm{Sl}_k(1)$, and $\mathrm{vol}(\mathcal{C} \cap \mathrm{Sl}_k(1)) = \mathrm{vol}(\mathrm{Sl}_k(1))/\det G$. The volume of $\mathrm{Sl}_k(1)$ is finite and positive, as the set contains the cube $[0, 1/k]^k$; only here is a volume cancelled. So the number is $1/\prod_{l=1}^{k} \frac{q^l-1}{q-1}$, and the theorem follows, also when the slab $\mathrm{Sl}_k(\delta)$ has volume zero. □

LEAN `prod_mul_volume_inter_slab`

The proof evaluates the signed sum of Proposition 5.2 without computing it: the identity $\frac{\mathrm{dt(id)}}{k!} \sum_{\sigma'} \mathrm{sgn}(\sigma')/\mathrm{dt}(\sigma') = \prod_{l=1}^{k} \frac{q-1}{q^l-1}$ is obtained from the geometry of one letter.

6 Two dimension bounds modulo p

Lemma 6.1 (the number of flags)**.** *Let $\mathbb{F}$ be a finite field and $k \ge 0$. The index in $\mathrm{GL}_k(\mathbb{F})$ of the subgroup of the lower triangular matrices is at most $\prod_{l=1}^{k} ((\#\mathbb{F})^l - 1)/(\#\mathbb{F} - 1)$.*

Proof. The subgroup has $(\#\mathbb{F}-1)^k (\#\mathbb{F})^{k(k-1)/2}$ elements, the lower triangular matrices with units on the diagonal, and Input 4 gives the order of the group; the quotient is the product. □

LEAN `index_borel_le` · `card_GL_eq_prod`

Lemma 6.2 (the excess of a step)**.** *In Setting 2.2 with $\mathcal{O}$ a field, let i_0, i_1 be indices, s_0 a letter and ξ a vector in $\mathbb{R}^{k\times L}$. Put $\eta = \mathrm{St}_{\mathrm{par}_T, P_T, 1}(\xi)$. Then*

$$\langle \mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot), \eta \rangle = \Big(1 - \frac{1}{q_T}\Big) \cdot \Big(\eta(\mathrm{rt}_{T,s_0}(i_0,i_1)) - (\xi(i_0,s_0) - \xi(i_1,s_0))\Big).$$

Proof. Let $\mathrm{df}_s = \xi(i_0,s) - \xi(i_1,s)$, and write η^+_s, η^-_s for the values of η at $\mathrm{rt}_{T,s}(i_0,i_1)$ and $\mathrm{rt}_{T,s}(i_1,i_0)$. For every letter, even or odd, the definition of the step gives $\eta^+_s - \eta^-_s = \mathrm{df}_s - P_T\,\mathrm{df}_{s+1}$. By the definition of the excess weight, in which the root variable of s_0 has the coefficient $P_T^L/q_T = 1$, the excess of η at s_0 is

$$\Big(1 - \frac{1}{q_T}\Big)\eta^+_{s_0} + \frac{1}{q_T} \sum_s P_T^{[s-s_0]}(\eta^+_s - \eta^-_s) = \Big(1 - \frac{1}{q_T}\Big)\eta^+_{s_0} + \frac{1}{q_T} \sum_s P_T^{[s-s_0]}(\mathrm{df}_s - P_T\,\mathrm{df}_{s+1}),$$

and the last sum, taken around the circle from s_0, telescopes to

$$\mathrm{df}_{s_0} - P_T^L\,\mathrm{df}_{s_0} = (1 - q_T)\,\mathrm{df}_{s_0}.$$ □

LEAN `TwistingData.excessWeight_dotProduct_permStep`

By this lemma, $\mathrm{St}_{\mathrm{par}_T,P_T,1}(\xi)$ lies in $\mathrm{Ec}_T(i_1;0)$ if and only if ξ lies in $\mathrm{Pc}_{\mathrm{par}_T,P_T}$: the set $\mathcal{C} = \mathrm{Ec}_T(i_1;0)$ satisfies the hypothesis of Theorem 2 for $\mathrm{par} = \mathrm{par}_T$ and $\varrho = P_T$, whatever i_1 is.

Lemma 6.3 (a point deep inside the cone)**.** *In Setting 2.2 with $\mathcal{O}$ a field, let i_0, i_1 be indices with $i_0 + 1 = i_1$. There is a vector σ° in $\mathrm{Ec}_T(i_1;-1)$ with $0 \le \sigma^\circ(v) \le P_T^{3i_1}$ for every variable v.*

Proof. Let

$$\mathrm{g}_i = 2\,P_T^{2(i_0-i)} \quad \text{for } i \le i_0 \qquad \text{and} \qquad \mathrm{g}_i = 0 \quad \text{for } i > i_0,$$

so that $\mathrm{g}_i = P_T^2 \mathrm{g}_{i+1} + 2\,[i+1 = i_1]$. Let $\xi(i,s) = \mathrm{g}_i$ for even s and $\xi(i,s) = P_T \mathrm{g}_i$ for odd s, and

$$\sigma^\circ = \mathrm{St}_{\mathrm{par}_T,P_T,1}(\xi).$$

Then $\sigma^\circ(i,s) = (P_T^2 - 1)\mathrm{g}_i$ for even s and 0 for odd s, which lies between 0 and $P_T^{3i_1}$. By Lemma 6.2, the excess of σ° at s_0 for the indices i, $i+1$ is $(1 - 1/q_T)$ times

$$\begin{aligned} (P_T^2 - 1)\mathrm{g}_{i+1} - (\mathrm{g}_i - \mathrm{g}_{i+1}) = -2\,[i+1 = i_1] \qquad & \text{if } s_0 \text{ is even,} \\ -P_T(\mathrm{g}_i - \mathrm{g}_{i+1}) \le -2\,[i+1 = i_1] \qquad & \text{if } s_0 \text{ is odd;} \end{aligned}$$

and $2(1 - 1/q_T) \ge 1$. □

LEAN `TwistingData.exists_mem_excessCone_mem_Icc`

Lemma 6.4 (the volume of a slice of a simplex)**.** *Let $n' \ge 0$ be a natural number and $\delta \le \delta'$ real numbers. The set of the η in $\mathbb{R}^{n'+1}$ with all coordinates ≥ 0 and $\delta - 1 \le \sum_i \eta_i \le \delta$ has volume at most $|{\delta'}^{n'}/n'!|$.*

Proof. If $\delta' < 0$ the set is empty. Otherwise argue by induction on n'. For $n' = 0$ the set lies in an interval of length 1. For the step, the slice at a value η_0 of the first coordinate is empty unless $0 \le \eta_0 \le \delta \le \delta'$, and is then a set of the same kind in one dimension less, for $\delta - \eta_0 \le \delta' - \eta_0$; and $\int_0^{\delta'} (\delta' - \eta_0)^{n'-1}/(n'-1)!\, d\eta_0 = {\delta'}^{n'}/n'!$. □

LEAN `volume_sum_mem_Icc_le`

Proposition 6.5 (forms obeying the excess condition, against a volume)**.** *In Setting 2.2, let the ring of T be a field $\mathbb{F}$ of characteristic p, let i_0, i_1 be indices with $i_0 + 1 = i_1$, n a natural number and h a real number. Write Lev° for the Levi subgroup $\mathrm{Lev}_{\tau_{k,i_1}(\cdot)}(W)$, and Par° for the parahoric subgroup of the labelling $i \mapsto i$, and let $\delta_s = n + k + 1$ for every letter s. Then*

$$\dim_{\mathbb{F}} \mathrm{Ex}_{T,n}^{i_0,i_1}(0;h) \;\le\; [\mathrm{Lev}^\circ : \mathrm{Lev}^\circ \cap \mathrm{Par}^\circ] \cdot \mathrm{vol}\Big(\mathrm{Ec}_T(i_1; h + L(k+1)) \cap \mathrm{Sl}_k(\delta)\Big).$$

Proof. Write $\Xi = \mathrm{Ex}_{T,n}^{i_0,i_1}(0;h)$ and $\mathcal{C}$ for the set on the right; $\mathcal{C}$ is bounded and convex. The number of the points of $\mathcal{C}$ with coordinates in $\frac{1}{Q}\mathbb{Z}$, divided by Q^{kL}, tends to $\mathrm{vol}(\mathcal{C})$ as the natural number Q grows, a bounded convex set having a boundary of measure zero. So it suffices to show, for $Q = q_T^l$ with $l \ge 1$, that

$$Q^{kL} \cdot \dim_{\mathbb{F}} \Xi \;\le\; [\mathrm{Lev}^\circ : \mathrm{Lev}^\circ \cap \mathrm{Par}^\circ] \cdot \#(\mathcal{C} \cap \tfrac{1}{Q}\mathbb{Z}^{k\times L}). \tag{9}$$

The ring of T being a field of characteristic p, we have $p = 0$ and $\varpi = 0$ in $\mathbb{F}$, and $\iota_{s+j}(v) = \iota_s(v)^{P_T^j}$ by Lemma 3.1(a); in particular $\iota_s(v)^Q = \iota_s(v)$. Hence $[\gamma]_T$

commutes with the substitution $x_v \mapsto x_v^Q$, and for a form F the polynomial $F(x^Q)$ is sent by $[\gamma]_T$ to $(\rho_{T,n}(\gamma)F)(x^Q)$ (Lemma 3.1(c)).

Amplification. Let $\mathcal{U}$ be the set of the functions ν from the variables to $\{0, \dots, Q-1\}$. For ν in $\mathcal{U}$ let $\hat{\nu}$ be the exponent with

$$\hat{\nu}(i,s) = \nu(i,s) + Q\,[i = i_0]\left(k - \left\lfloor \sum_{i'} \nu(i',s)/Q \right\rfloor\right);$$

it is congruent to ν modulo Q, and its degree in each letter lies in $[kQ, kQ+Q)$. Send a tuple $(F_\nu)_{\nu\in\mathcal{U}}$ of elements of Ξ to the polynomial $\Phi = \sum_\nu x^{\hat{\nu}} F_\nu(x^Q)$. The exponents of the ν-th summand are congruent to ν modulo Q, so the coefficient of $x^{Q\beta+\hat{\nu}}$ in Φ is $F_\nu(\beta)$, and the map is injective. Let Γ be a set of representatives of the right cosets $(\mathrm{Lev}^\circ \cap \mathrm{Par}^\circ)\gamma$ in Lev°. We show that the linear map sending $(F_\nu)_\nu$ to the family of the coefficients of $x^{Q\eta}$ in $[\gamma]_T\Phi$, for γ in Γ and η in $\mathcal{C} \cap \frac{1}{Q}\mathbb{Z}^{k\times L}$, is injective; comparing dimensions, this is (9).

A least term. Let ω be the weight with $\omega(i,s) = i$ for even s and $\omega(i,s) = -i$ for odd s. Suppose $\Phi \neq 0$. Among the pairs of a γ in Γ and an exponent α with nonzero coefficient in $[\gamma]_T\Phi$, choose one, (γ_0, α), with $\langle\omega, \alpha\rangle$ least. We show that α/Q lies in $\mathcal{C}$; then the coefficient of x^α in $[\gamma_0]_T\Phi$ is one of the coordinates of the image and is not zero.

By the commutation above,

$$[\gamma_0]_T\Phi = \sum_\nu ([\gamma_0]_T x^{\hat{\nu}}) \cdot (\rho_{T,n}(\gamma_0)F_\nu)(x^Q),$$

so $\alpha = Q\beta + \alpha''$ for some ν, a family β with $(\rho_{T,n}(\gamma_0)F_\nu)(\beta) \neq 0$, and an exponent α'' of $[\gamma_0]_T x^{\hat{\nu}}$. The action preserves the degree in each letter, so the degree of α'' in each letter lies in $[kQ, kQ+Q]$. Hence α/Q has coordinates ≥ 0 and its sums over the indices lie in $[n+k, n+k+1]$: it lies in the slab.

The excess at (i_0, i_1). As F_ν lies in Ξ and γ_0 in Lev°, the family β has excess at most h at every letter. The excess of α'' is at most its degree, at most $L(kQ+Q)$, by Lemma 3.3. So the excess of α/Q is at most $h + L(k+1)$.

The excess at the other pairs. Let i, $i+1$ be indices with $i+1 \neq i_1$, and s_0 a letter. We apply Theorem 1 to the indices i, $i+1$, the labelling $\tau_{k,i_1}(\cdot)$, which takes the same value at both, the weight ω, for which the differences of the hypothesis are equal to 1, the polynomial $[\gamma_0]_T\Phi$, the exponent α and $e = 0$. Its coefficient at x^α is not zero, that is, not divisible by $\varpi = 0$. For γ in Lev° write $\gamma^{-1}\gamma_0 = \gamma'\gamma_1$ with γ' in $\mathrm{Lev}^\circ \cap \mathrm{Par}^\circ$ and γ_1 in Γ. All exponents of $[\gamma_1]_T\Phi$ have weight at least $\langle\omega, \alpha\rangle$, by the choice of the pair. By Lemma 3.2, for the labelling $i \mapsto i$, and since $p = 0$ in $\mathbb{F}$, the element γ' sends a variable $x_{i',s}$ to a combination of the variables $x_{l,s}$ with $l \geq i'$ if s is even and with $l \leq i'$ if s is odd: of variables of weight at least $\omega(i',s)$. So all exponents of $[\gamma^{-1}]_T[\gamma_0]_T\Phi$ have weight at least $\langle\omega, \alpha\rangle$, which is the hypothesis of Theorem 1 for $\varpi = 0$. The theorem gives that the excess of α at s_0 for the indices i, $i+1$ is at most 0. □

LEAN `TwistingData.finrank_excessCond_le_volume` · `TwistingData.root_lemma` · `TwistingData.p_dvd_letterMatrix_of_mem_parahoric` · `TwistingData.excessWeight_mem_Icc`

Proof of Theorem 3(a). There is an index, so $k \geq 1$. Of the size conditions we use $\kappa \leq 1$, $1 \leq h$,

$$\frac{2(L+2)k}{h} \leq \kappa \qquad \text{and} \qquad (h + L(k+1))\,k\,P_T^{3i_1} + k + 2 \leq \frac{n}{h}. \tag{10}$$

Let σ° be the vector of Lemma 6.3 and $\sigma^\bullet = (h + L(k+1))\,\sigma^\circ$. The conditions that define the cones are linear, so the translation by $\sigma^\bullet$ maps $\mathrm{Ec}_T(i_1; h + L(k+1)) \cap \mathrm{Sl}_k(\delta)$, with $\delta_s = n + k + 1$, into $\mathrm{Ec}_T(i_1; 0) \cap \mathrm{Sl}_k(\delta')$ with $\delta'_s = n + k + 1 + \sum_i \sigma^\bullet(i,s)$. Let Lev° and Par° be as in Proposition 6.5. Both lie in the parahoric subgroup $\mathrm{Par}_{\tau_{k,i_1}(\cdot)}(W)$, so its index times $[\mathrm{Lev}^\circ : \mathrm{Lev}^\circ \cap \mathrm{Par}^\circ]$ is at most $[\mathrm{GL}_k(W) : \mathrm{Par}^\circ]$. Now Par° is the preimage of the group of the lower triangular matrices under the reduction map from $\mathrm{GL}_k(W)$ to $\mathrm{GL}_k(\mathbb{F}_W)$. So its index is the index of the lower triangular matrices of the image in the image, which is at most their index in $\mathrm{GL}_k(\mathbb{F}_W)$. (The two are equal, the reduction map being surjective: a matrix over the local ring W is invertible when its reduction is. The formal proof uses the inequality only.) By Lemma 6.1 and $\#\mathbb{F}_W = q_T$, that index is at most the product

$$\prod_{l=1}^{k} \frac{q_T^l - 1}{q_T - 1}.$$

By Theorem 2, with the remark after Lemma 6.2, this product times the volume of $\mathrm{Ec}_T(i_1; 0) \cap \mathrm{Sl}_k(\delta')$ is $\mathrm{vol}(\mathrm{Sl}_k(\delta'))$. With Proposition 6.5 we get

$$\left[\mathrm{GL}_k(W) : \mathrm{Par}_{\tau_{k,i_1}(\cdot)}(W)\right] \cdot \dim_{\mathbb{F}} \mathrm{Ex}_{T,n}^{i_0,i_1}(0; h) \;\le\; \mathrm{vol}(\mathrm{Sl}_k(\delta')).$$

The slab is contained in the product over the letters of the sets of Lemma 6.4 in $\mathbb{R}^k$. By the second condition of (10) and $\sigma^\circ \le P_T^{3i_1}$, $\delta'_s \le n + n/h \le n\exp(1/h)$. So the volume is at most $\left((n\exp(1/h))^{k-1}/(k-1)!\right)^L$, and

$$\frac{n^{k-1}}{(k-1)!} \;\le\; \binom{n+k-1}{k-1} = \#\mathrm{Mon}_{k,n}.$$

Finally $\exp((k-1)L/h) \le 1 + \kappa$: the exponent is at most $\kappa/2 \le \frac{1}{2}$ by the first condition of (10), and $\exp(\theta) \le 1 + 2\theta$ for $0 \le \theta \le \frac{1}{2}$. □

LEAN `TwistingData.index_mul_finrank_excessCond_le`

Proposition 6.6 (a nonzero deep form has a costly monomial)**.** *In Setting 2.2, let the ring of T be a field $\mathbb{F}$ of characteristic p, let n, $\mathfrak{t}$, j be natural numbers with $2\mathfrak{t} \le k$ and $2\mathfrak{t} < L$, and let F be a nonzero form in $\mathrm{Dp}_{T,\mathfrak{t}}^{k,n}(j)$. Then there is a family β with $F(\beta) \ne 0$ and*

$$j \;\le\; \sum_{v=(i,s)} \beta_s(i)\,\frac{\mathrm{dp}_{T,\mathfrak{t}}(v)}{P_T^{e_i}}, \qquad e_i = 2\mathfrak{t} \;\; \textit{if } i \ge 2\mathfrak{t}, \quad e_i = 1 \;\; \textit{if } i < 2\mathfrak{t}.$$

Proof. Let $\mathbb{F}'$ be the field of rational functions over $\mathbb{F}$ in the variables that are not deep, and regard the polynomial of F as a polynomial Φ over $\mathbb{F}'$ in the deep variables; it is not zero. We apply Input 3 over $\mathbb{F}'$, with $\mathcal{V}$ the set of the deep variables and $\varkappa(i,s) = P_T^{e_i}$. Then $\prod_v \varkappa(v) = P_T^{(L/2)\sum_i e_i} = q_T^{\mathfrak{t}(k-2\mathfrak{t}+1)}$ by Lemma 3.4. A monomial of Φ of cost at least j comes from a family β with $F(\beta) \ne 0$ whose deep part it is, and the cost is the sum of the statement. It remains to give the points and the polynomials.

The points. Let $\mathcal{K}$ be the set of the pairs (l, l') of indices with $l < \mathfrak{t}$ and either $l' = l + \mathfrak{t}$ or $l' \ge 2\mathfrak{t}$; it has $\mathfrak{t}(k - 2\mathfrak{t} + 1)$ elements. Let $\mathcal{S}$ be the set of the functions $\mathfrak{s}$ from $\mathcal{K}$ to $\mathbb{F}_W$, so that $\#\mathcal{S} = q_T^{\mathfrak{t}(k-2\mathfrak{t}+1)}$. For $\mathfrak{s}$ in $\mathcal{S}$ choose a lift $\tilde{\mathfrak{s}}_{l,l'}$ in W of each value and let $\gamma_{\mathfrak{s}} = 1 + \sum_{(l,l')\in\mathcal{K}} \tilde{\mathfrak{s}}_{l,l'} E_{ll'}$, an element of $\mathrm{GL}_k(W)$ with inverse $1 - \sum \tilde{\mathfrak{s}}_{l,l'} E_{ll'}$,

the rows and the columns that occur being disjoint. By Lemma 3.1(b), $[\gamma_{\mathfrak{s}}^{-1}]_T$ fixes the variables that are not deep and sends a deep variable x_v to $x_v - \upsilon_{\mathfrak{s}}(v)$, where

$$\upsilon_{\mathfrak{s}}(l', s) = \sum_{l} \iota_s(\tilde{\mathfrak{s}}_{l,l'})\, x_{l,s} \quad (s \text{ even}), \qquad \upsilon_{\mathfrak{s}}(l, s) = -\sum_{l'} \iota_s(\tilde{\mathfrak{s}}_{l,l'})\, x_{l',s} \quad (s \text{ odd}),$$

the sums being over the pairs in $\mathcal{K}$ with the given member; these are elements of $\mathbb{F}'$, the variables on the right not being deep. As F lies in $\mathrm{Dp}^{k,n}_{T,\mathfrak{t}}(j)$, every monomial of $\rho_{T,n}(\gamma_{\mathfrak{s}})F$ has at least j deep variables, counted with multiplicity; applying $[\gamma_{\mathfrak{s}}^{-1}]_T$ and Lemma 3.1(c), Φ is a combination of products of at least j factors $x_v - \upsilon_{\mathfrak{s}}(v)$. So Φ lies in the j-th power of the ideal of the point $\upsilon_{\mathfrak{s}}$.

The polynomials. Fix a letter s'. For a pair (l, l') in $\mathcal{K}$ choose a natural number $j_{l,l'}$: it is 0 if $l' = l + \mathfrak{t}$; if $l' \geq 2\mathfrak{t}$ it is the one of $2l$, $2l+1$ for which the letter $s' - j_{l,l'}$ is even. Let $v_{l,l'}$ be the deep variable $(l', s' - j_{l,l'})$ if that letter is even, and (l, s') if $j_{l,l'} = 0$ and s' is odd. In each case $j_{l,l'} < e$, where $P_T^e = \varkappa(v_{l,l'})$: for $l' \geq 2\mathfrak{t}$ we have $j_{l,l'} \leq 2\mathfrak{t} - 1$ and $e = 2\mathfrak{t}$. By Lemma 3.1(a) and $p = 0$,

$$\upsilon_{\mathfrak{s}}(v_{l,l'})^{P_T^{j_{l,l'}}} = \sum_{(l_1,l_1')\in\mathcal{K}} C_{(l,l'),(l_1,l_1')} \cdot \iota_{s'}(\tilde{\mathfrak{s}}_{l_1,l_1'}),$$

with a matrix C over $\mathbb{F}'$ that does not depend on $\mathfrak{s}$: its entries are, up to sign, the $P_T^{j_{l,l'}}$-th powers of the variables that occur in the formula for $\upsilon_{\mathfrak{s}}(v_{l,l'})$. We claim that $\det C \neq 0$. If s' is even, C is block diagonal for the second members: the block of the pairs $(l, l+\mathfrak{t})$ is diagonal with the entries $x_{l,s'}$, and the block of each $l' \geq 2\mathfrak{t}$ is the matrix $(x_{l_1,s'-2l}^{P_T^{2l}})_{l,l_1}$, whose entries are powers of $\mathfrak{t}^2$ distinct variables, the letters $s' - 2l$ being distinct because $2\mathfrak{t} < L$. If s' is odd, order the pairs $(l, l+\mathfrak{t})$ first: C is block triangular, with a diagonal block of entries $-x_{l+\mathfrak{t},s'}$ and blocks $(x_{l_1,s'-2l-1}^{P_T^{2l+1}})_{l,l_1}$. A matrix whose entries are powers of distinct variables has a nonzero determinant. So each $\iota_{s'}(\tilde{\mathfrak{s}}_{l_1,l_1'})$ is a combination over $\mathbb{F}'$, with coefficients independent of $\mathfrak{s}$, of the values at $\upsilon_{\mathfrak{s}}$ of the monomials $x_{v_{l,l'}}^{P_T^{j_{l,l'}}}$, which cost $P_T^{j_{l,l'}}/\varkappa(v_{l,l'}) < 1$.

Now let v be a deep variable of the letter s, and $P_T^e = \varkappa(v)$. By Lemma 3.1(a), $\upsilon_{\mathfrak{s}}(v)^{\varkappa(v)}$ is a combination, with coefficients in $\mathbb{F}'$ independent of $\mathfrak{s}$, of the $\iota_{s+e}(\tilde{\mathfrak{s}}_{l_1,l_1'})$; by the last paragraph for $s' = s + e$ it is the value at $\upsilon_{\mathfrak{s}}$ of a polynomial Φ_v whose monomials cost less than 1. The same paragraph, for any letter s', shows that the point $\upsilon_{\mathfrak{s}}$ determines the $\iota_{s'}(\tilde{\mathfrak{s}}_{l_1,l_1'})$, hence $\mathfrak{s}$: two elements of W with the same image under $\iota_{s'}$ differ by a non-unit. So the points are pairwise distinct, and Input 3 applies. □

LEAN `TwistingData.exists_le_weight_of_mem_deepForms` · `exists_le_cost_of_vanishing` · `TwistingData.sum_deepIndicator`

Proof of Theorem 3(b). From the size conditions: $0 < \mathfrak{t}$, $2\mathfrak{t} \leq k$, $1 \leq y$, $n < P_T^\lambda$ and $L = 2\lambda$, and $P_T^{3\mathfrak{t}} \leq n$ from the ninth condition; so $3\mathfrak{t} < \lambda$ and $2\mathfrak{t} < L$. For a family β let $\mathrm{cost}(\beta)$ be the sum of Proposition 6.6. By that proposition, a form in $\mathrm{Dp}^{k,n}_{T,\mathfrak{t}}(j)$ that vanishes at all β with $j \leq \mathrm{cost}(\beta)$ is zero; so $\dim_{\mathbb{F}} \mathrm{Dp}^{k,n}_{T,\mathfrak{t}}(j)$ is at most the number of these β. Summing over $j < j_0$, each β is counted at most $\mathrm{cost}(\beta) + 1$ times:

$$\sum_{j<j_0} \dim_{\mathbb{F}} \mathrm{Dp}^{k,n}_{T,\mathfrak{t}}(j) \;\leq\; \sum_{\beta} (1 + \mathrm{cost}(\beta)).$$

The cyclic shifts of the indices permute the families. Averaging over them replaces $\beta_s(i)$ by n/k, so, by Lemma 3.4,

$$\sum_{\beta} \operatorname{cost}(\beta) = \left(\#\mathrm{Mon}_{k,n}\right)^{L} \cdot \frac{n}{k} \cdot \frac{L}{2} \cdot \left(\frac{k-2\mathfrak{t}}{P_T^{2\mathfrak{t}}} + \frac{2\mathfrak{t}}{P_T} \right) \;\le\; \left(\#\mathrm{Mon}_{k,n}\right)^{L} \cdot L\, n \left(\frac{1}{P_T^{2\mathfrak{t}}} + \frac{\mathfrak{t}^2}{k\, P_T} \right),$$

which is at most $z\,(\#\mathrm{Mon}_{k,n})^{L}$ by the tenth condition. □

LEAN `TwistingData.sum_finrank_deepForms_le`

7 Conjugation-invariant means

In this section the variables are the entries $x_{i,i'}$ of one generic matrix, and for a finite set $\mathcal{V}$ of variables $\mathrm{Mon}_{\mathcal{V}}(n)$ is the set of the exponents of degree n on $\mathcal{V}$.

Lemma 7.1 (density of the points where a form is a unit)**.** *Let W be a local ring, $\mathcal{O}$ a ring, $\chi\colon W \to \mathcal{O}$ a ring homomorphism, $\mathcal{V}$ a finite set, and n, n' natural numbers. Let Φ_0 be a homogeneous polynomial of degree n' in $W[x_{\mathcal{V}}]$, with $n + n' \le \#\mathbb{F}_W$, and let v_0 be a point of $W^{\mathcal{V}}$ at which Φ_0 takes a unit value. Let M_1 be an $\mathcal{O}$-submodule of $\mathcal{O}^{\mathrm{Mon}_{\mathcal{V}}(n)}$ that contains the vector $(\chi(v^{\alpha}))_{\alpha}$ for every point v of $W^{\mathcal{V}}$ with $\Phi_0(v)$ a unit. Then $M_1 = \mathcal{O}^{\mathrm{Mon}_{\mathcal{V}}(n)}$.*

Proof. Let M_0 be the W-submodule of $W^{\mathrm{Mon}_{\mathcal{V}}(n)}$ of the vectors whose image under χ lies in M_1. It suffices that M_0 is everything, for then M_1 contains the unit vectors. By Nakayama's lemma, the finitely generated W-module $W^{\mathrm{Mon}_{\mathcal{V}}(n)}/M_0$ is zero if every W-linear map $\mathcal{L}$ from it to $\mathbb{F}_W$ is zero. Given such a map, let Φ be the polynomial over $\mathbb{F}_W$ with the coefficient $\mathcal{L}$ of the α-th unit vector at x^{α}; it is homogeneous of degree n. If v is a point at which Φ_0 is a unit, then $(v^{\alpha})_{\alpha}$ lies in M_0, so Φ vanishes at the residue of v. Hence the product of Φ with the reduction of Φ_0 vanishes at every point of $\mathbb{F}_W^{\mathcal{V}}$. It is homogeneous of degree $n + n' \le \#\mathbb{F}_W$, and such a polynomial is zero, by the zero test that follows; the reduction of Φ_0 is not zero, because of v_0; so $\Phi = 0$ and $\mathcal{L} = 0$.

The zero test. Let $\mathbb{F}$ be a field and Φ' a polynomial in $\mathbb{F}[x_{\mathcal{V}}]$ that vanishes at every point of $\mathbb{F}^{\mathcal{V}}$. First, if $\mathbb{F}$ is finite and the degree of Φ' in each variable is less than $\#\mathbb{F}$, then $\Phi' = 0$. This is proved by induction on $\#\mathcal{V}$: write Φ' as a polynomial in one of the variables, with coefficients in the others; at each point of the other variables it has more zeros than its degree, so the coefficients vanish at every point, and they are zero by the induction hypothesis. Secondly, if $\mathbb{F}$ is finite and Φ' is homogeneous of a degree $l \le \#\mathbb{F}$, then $\Phi' = 0$. For $l < \#\mathbb{F}$ this is the first statement. Let $l = \#\mathbb{F}$. The monomials of degree l in which some variable has an exponent that is not less than $\#\mathbb{F}$ are the powers $x_v^{\#\mathbb{F}}$. Replace each of them by x_v. The values on $\mathbb{F}^{\mathcal{V}}$ do not change, as $v^{\#\mathbb{F}} = v$ for v in $\mathbb{F}$. The monomials stay distinct and keep their coefficients, as $\#\mathbb{F} \ge 2$: the new ones have degree 1, the others degree $\#\mathbb{F}$. The new polynomial has degree less than $\#\mathbb{F}$ in each variable, so it is zero by the first statement, and then every coefficient of Φ' is zero. In the proof above $\mathbb{F}$ is the residue field $\mathbb{F}_W$. If it is infinite, the count $\#\mathbb{F}_W$ is 0 by the convention, so $n + n' = 0$ and the product is a constant; it vanishes at a point, so it is zero. The case $l = \#\mathbb{F}$ belongs to the statement of the lemma, as in the formal text; there the polynomial $x_v^{\#\mathbb{F}} - x_v$ shows that homogeneity cannot be dropped. □

LEAN `ClassMean.eq_top_of_eval_monomial`

Lemma 7.2 (an integral invariant diagonal form)**.** *Let $\mathcal{O}$ be a valuation domain of characteristic zero, $\mathcal{V}$ a finite set, p a prime number that is not a unit in $\mathcal{O}$, and e a natural number. There is a function w from the exponents on $\mathcal{V}$ to $\mathcal{O}$ such that*

(i) *for every exponent α with $|\alpha| < p^e$: $p^{\#\mathcal{V}\cdot e} = \binom{|\alpha|}{\alpha} w(\alpha)$, where the multinomial coefficient $\binom{|\alpha|}{\alpha}$ is $|\alpha|!/\prod_v \alpha(v)!$;*

(ii) *for every square matrix G over $\mathcal{O}$ indexed by $\mathcal{V}$ and all exponents α, α': the coefficient of x^α in the linear substitution of G applied to $x^{\alpha'}$, times $w(\alpha)$, equals $w(\alpha')$ times the coefficient of $x^{\alpha'}$ in the linear substitution of G^{T} applied to x^α.*

Proof. A multinomial coefficient of degree l is a product of $\#\mathcal{V}$ binomial coefficients $\binom{l'}{j}$ with $j \le l' \le l$. Let $l' < p^e$. By Legendre's formula for the power of p in a factorial, the exponent of p in $\binom{l'}{j}$ is

$$\sum_{r\ge 1}\Big(\Big\lfloor\frac{l'}{p^r}\Big\rfloor - \Big\lfloor\frac{j}{p^r}\Big\rfloor - \Big\lfloor\frac{l'-j}{p^r}\Big\rfloor\Big).$$

Each term is 0 or 1, and it is 0 when $p^r > l'$, hence for $r \ge e$; so the exponent is at most e. The part of $\binom{l'}{j}$ prime to p is a unit of $\mathcal{O}$. Indeed, an integer prime to p has a multiple that is congruent to 1 modulo p; as p is not a unit, it lies in the maximal ideal $\mathfrak{m}$ of the valuation domain $\mathcal{O}$; so that multiple, and with it the integer, does not lie in $\mathfrak{m}$, and the integer is a unit. Hence $\binom{l'}{j}$ divides p^e in $\mathcal{O}$, and $\binom{|\alpha|}{\alpha}$ divides $p^{\#\mathcal{V}\cdot e}$ when $|\alpha| < p^e$; let $w(\alpha)$ be the quotient, and $w(\alpha) = 0$ for the other α. For (ii), expand the product $\prod_{v'}(\sum_v G_{vv'}x_v)^{\alpha'(v')}$: the coefficient of x^α is the sum, over the matrices $(m_{vv'})$ of natural numbers with row sums α and column sums α', of $\prod_{v'}\alpha'(v')! \cdot \prod_{v,v'} G_{vv'}^{m_{vv'}}/m_{vv'}!$. Multiplied by $\prod_v \alpha(v)!$ this is symmetric under transposition. So both coefficients of (ii) vanish unless $|\alpha| = |\alpha'|$, and then they differ by the factor $\prod \alpha'(v)!/\prod\alpha(v)! = \binom{|\alpha|}{\alpha}/\binom{|\alpha'|}{\alpha'}$, which is $w(\alpha')/w(\alpha)$ if the degree is less than p^e; otherwise both values of w are zero. □

LEAN `ClassMean.exists_invariant_diagonal_form`

Proposition 7.3 (an invariant mean with prescribed values)**.** *Let W be a local ring, $\mathcal{O}$ a valuation domain of characteristic zero, $\chi\colon W \to \mathcal{O}$ a ring homomorphism, k and n_0 natural numbers, and τ a labelling of the indices. Let p be a prime number that is not a unit in $\mathcal{O}$ and e a natural number with $n_0 < p^e$ and $n_0 + k < \#\mathbb{F}_W$. Let ω be a real function on the indices and Ω a set of real numbers. For an exponent α on the generic variables put $\mathrm{rw}(\alpha) = \sum_{i,i'} \alpha(i,i')\,\omega(i)$ and $\mathrm{cw}(\alpha) = \sum_{i,i'} \alpha(i,i')\,\omega(i')$. Then there is an $\mathcal{O}$-linear form $\mathcal{M}$ on the polynomials in the generic variables over $\mathcal{O}$ such that:*

(a) *$\mathcal{M}(\mathrm{cs}_\chi(\gamma)\Phi) = \mathcal{M}(\Phi)$ for every γ in $\mathrm{Lev}_\tau(W)$ and every polynomial Φ;*

(b) *$\mathcal{M}(x^\alpha) = 0$ for every α with $\mathrm{rw}(\alpha) \ne \mathrm{cw}(\alpha)$;*

(c) *for every α with $\mathrm{rw}(\alpha) \in \Omega$: $\mathcal{M}(x^\alpha)$ is $p^{k^2 e}$ times the value of x^α at the identity matrix if $|\alpha| \le n_0$, and $\mathcal{M}(x^\alpha) = 0$ if $|\alpha| > n_0$;*

(d) *$\mathcal{M}$ is an $\mathcal{O}$-linear combination of forms $\mathcal{L} \circ \mathrm{cs}_\chi(\gamma)$, with γ in $\mathrm{Lev}_\tau(W)$ and $\mathcal{L}$ an $\mathcal{O}$-linear form that vanishes at every x^α with $\mathrm{rw}(\alpha) \notin \Omega$.*

Proof. We construct, for each $j \le n_0$, a form $\mathcal{M}_j$ that vanishes on the monomials of degree other than j and has the four properties for the monomials of degree j; their sum is $\mathcal{M}$. Fix j.

The algebra. Let V_j be the free $\mathcal{O}$-module with the basis $e_{\mathbf{l}}$, for the sequences $\mathbf{l} = (l_1, \dots, l_j)$ of indices, and put $|\mathbf{l}|_\omega = \sum_r \omega(l_r)$. Let X^τ be the matrix with the entry $x_{i',i}$ at (i,i') if $\tau(i) = \tau(i')$ and 0 otherwise. An entry of its j-th Kronecker power is $\prod_r X^\tau_{l_r,l'_r}$, which is zero or the monomial x^α with $\alpha = \sum_r 1_{(l'_r,l_r)}$; then $\mathrm{rw}(\alpha) = |\mathbf{l}'|_\omega$ and $\mathrm{cw}(\alpha) = |\mathbf{l}|_\omega$. For α of degree j let S_α be the endomorphism of V_j whose matrix has the entry 1 where the Kronecker power has the entry x^α, and 0 elsewhere; for a vector $c = (c_\alpha)$ put $S(c) = \sum_\alpha c_\alpha S_\alpha$. Then for every linear form $\mathcal{L}$, $S((\mathcal{L}(x^\alpha))_\alpha)$ is $\mathcal{L}$ applied to the entries of the Kronecker power. In particular, for γ in $\mathrm{Lev}_\tau(W)$, the point with $x_{i',i} = \gamma_{ii'}$ gives a vector c_γ with $S(c_\gamma) = \chi(\gamma)^{\otimes j}$, the j-th Kronecker power of the matrix $\chi(\gamma)$.

Density. We claim: a submodule of the module of the vectors c that contains every c with $S(c) = \chi(\gamma)^{\otimes j}$ for some γ in $\mathrm{Lev}_\tau(W)$ is everything. This is Lemma 7.1 for the generic variables, the degree j and the polynomial $\Phi_0 = \det X^\tau$, which is homogeneous of degree k and equal to 1 at the point of the identity matrix; here $j + k \le n_0 + k < \#\mathbb{F}_W$. Indeed, at a point υ where $\det X^\tau$ is a unit, the value of X^τ is an element γ of the Levi subgroup, and $S((\chi(\upsilon^\alpha))_\alpha) = \chi(\gamma)^{\otimes j}$.

The module. Let V_j^Ω be the submodule of V_j spanned by the vectors $S(c)e_{\mathbf{l}}$, for all c and all $\mathbf{l}$ with $|\mathbf{l}|_\omega \in \Omega$. It is mapped into itself by every $S(c)$: by the density claim, used twice, it suffices to see that $\chi(\gamma)^{\otimes j}\chi(\gamma')^{\otimes j}e_{\mathbf{l}} = \chi(\gamma\gamma')^{\otimes j}e_{\mathbf{l}}$ lies in V_j^Ω. Being finitely generated and without torsion over the valuation domain $\mathcal{O}$, V_j^Ω is free.

The form. Let w be the function of Lemma 7.2 for the k^2 generic variables, the prime p and the exponent e. For a polynomial Φ with coefficients Φ_α let $\mathrm{K}(\Phi) = (w(\alpha)\Phi_\alpha)_{|\alpha|=j}$, and define

$$\mathcal{M}_j(\Phi) = \mathrm{tr}(S(\mathrm{K}(\Phi)) \,\big|\, V_j^\Omega), \qquad \text{so that} \quad \mathcal{M}_j(x^\alpha) = w(\alpha)\,\mathrm{tr}(S_\alpha | V_j^\Omega) \ \text{ for } |\alpha| = j.$$

Equivariance. For γ in $\mathrm{Lev}_\tau(W)$,

$$S(\mathrm{K}(\mathrm{cs}_\chi(\gamma)\Phi)) = \chi(\gamma)^{\otimes j}\, S(\mathrm{K}(\Phi))\, \chi(\gamma^{-1})^{\otimes j}. \tag{11}$$

Indeed $\mathrm{cs}_\chi(\gamma)$ is the linear substitution of a matrix G indexed by the generic variables. By Lemma 7.2(ii) the α-th coordinate of $\mathrm{K}(\mathrm{cs}_\chi(\gamma)\Phi)$ is $\sum_{\alpha'} w(\alpha')\Phi_{\alpha'}$ times the coefficient of $x^{\alpha'}$ in the substitution of G^{T} applied to x^α. So the left side of (11) is $\sum_{\alpha'} w(\alpha')\Phi_{\alpha'}$ times the matrix of the coefficients of $x^{\alpha'}$ in the Kronecker power of the image of X^τ under the substitution of G^{T}. That substitution replaces the matrix $(x_{i,i'})$ by $\chi(\gamma^{-1})^{\mathsf{T}}(x_{i,i'})\chi(\gamma)^{\mathsf{T}}$, and therefore X^τ, which is its transpose cut down to the pattern of the Levi subgroup, by $\chi(\gamma)X^\tau\chi(\gamma)^{-1}$, the matrices $\chi(\gamma)$ and $\chi(\gamma)^{-1}$ having that pattern. Taking coefficients gives the right side.

The four properties. (a) By (11) and because $\chi(\gamma)^{\otimes j}$ and its inverse map V_j^Ω to itself, the two traces agree. (b) S_α sends $e_{\mathbf{l}'}$ to zero unless $|\mathbf{l}'|_\omega = \mathrm{rw}(\alpha)$, and then to a combination of the $e_{\mathbf{l}}$ with $|\mathbf{l}|_\omega = \mathrm{cw}(\alpha)$. If the two weights differ, $S_\alpha^2 = 0$, and a nilpotent endomorphism of a free module over a domain has trace zero. (c) If $\mathrm{rw}(\alpha) \in \Omega$, then S_α maps V_j into V_j^Ω, so its trace on V_j^Ω is its trace on V_j, the number of the sequences $\mathbf{l}$ with $\sum_r 1_{(l_r,l_r)} = \alpha$. That number is $\binom{|\alpha|}{\alpha}$ if α is supported on the variables $x_{i,i}$ and 0 otherwise; and the value of x^α at the identity matrix is 1 or 0 in the same cases. With Lemma 7.2(i), $j \le n_0 < p^e$, this is (c). (d) Choose a basis of V_j^Ω; the trace is the sum, over the basis, of forms $\Phi \mapsto \mathcal{L}'(S(\mathrm{K}(\Phi))\,\mathbf{v})$ with $\mathbf{v}$ in V_j^Ω and $\mathcal{L}'$ a linear form

on V_j^{Ω}. By the definition of V_j^{Ω} and the density claim we may take $\mathbf{v} = \chi(\gamma)^{\otimes j} e_{\mathbf{l}}$ with $|\mathbf{l}|_\omega \in \Omega$. By (11) for γ^{-1}, $S(\mathrm{K}(\Phi))\chi(\gamma)^{\otimes j} e_{\mathbf{l}} = \chi(\gamma)^{\otimes j} S(\mathrm{K}(\mathrm{cs}_\chi(\gamma^{-1})\Phi))e_{\mathbf{l}}$, so the form is $\mathcal{L} \circ \mathrm{cs}_\chi(\gamma^{-1})$ with $\mathcal{L}(\Phi) = \mathcal{L}'(\chi(\gamma)^{\otimes j} S(\mathrm{K}(\Phi))e_{\mathbf{l}})$, and $\mathcal{L}(x^\alpha) = 0$ unless $\mathrm{rw}(\alpha) = |\mathbf{l}|_\omega$, which lies in Ω. □

LEAN `ClassMean.exists_mean` · `ClassMean.eq_top_of_eval_monomial` · `ClassMean.exists_invariant_diagonal_form`

The image of S is the Schur algebra of the Levi subgroup in degree j, an order spanned by the Kronecker powers of the group elements; V_j^{Ω} is the part of the tensor space generated by the weight vectors with weight in Ω, and $\mathcal{M}_j$ is its character, read as a function on the dual of the Schur algebra. The function w is the price of integrality: the identification of polynomials of degree j with that dual has the multinomial coefficients as denominators.

8 The Frobenius operator and the projector

Lemma 8.1 (the Frobenius operator under a ring homomorphism)**.** *In Setting 2.2, let* $\mathfrak{t}$, λ, n *be natural numbers,* $\mathcal{R}$ *a ring,* $\psi = (\psi(s,j))$ *matrices in* $\mathrm{M}_k(\mathcal{R})$*,* $\chi\colon \mathcal{R} \to \mathcal{O}$ *a ring homomorphism, and* γ *an element of* $\mathrm{Lev}_{\tau_{k,\mathfrak{t}}(\cdot)}(W)$*. Then* χ*, applied to the entries of* $\mathrm{Fr}_{T,\mathfrak{t},\lambda,n}(\psi)$*, gives*

$$\rho_{T,n}(\gamma^{-1}) \cdot \mathrm{Fr}_{T,\mathfrak{t},\lambda,n}(\psi') \cdot \rho_{T,n}(\gamma), \qquad \psi'(s,j) = \mathrm{cj}_{T,\gamma,s}(\chi(\psi(s,j))).$$

Proof. Let Π_s^m and $\Pi_s'^m$ be the products of Definition 2.10(b) for ψ and ψ'; then

$$\chi(\Pi_s^m) = \iota_s(\gamma^{-1})\, \Pi_s'^m\, \iota_s(\gamma).$$

For an even letter this says that $\chi(\Pi_s^m)$ is $\Pi_s'^m$ conjugated by the letter matrices of γ. For an odd letter, taking transposed adjugates gives

$$\chi(\mathrm{adj}(\Pi_s^m))^{\mathsf{T}} = \iota_s(\gamma)^{\mathsf{T}}\, \mathrm{adj}(\Pi_s'^m)^{\mathsf{T}}\, \iota_s(\gamma^{-1})^{\mathsf{T}},$$

the determinants of $\iota_s(\gamma)$ and $\iota_s(\gamma^{-1})$ cancelling; and $\iota_s(\gamma)^{\mathsf{T}}$ is the letter matrix of γ^{-1} at an odd letter. The number $m = \lambda + \mathrm{dp}_{T,\mathfrak{t}}((i,s))$ depends only on the block of i, and the letter matrices of γ are block diagonal; so choosing the rows according to m commutes with these conjugations, and

$$\chi(B_s) = \gamma_{T,s}^{-1}\, B_s'\, \gamma_{T,s}.$$

Symmetric powers and Kronecker products are multiplicative. □

LEAN `TwistingData.frobOperator_map`

Lemma 8.2 (the Frobenius operator in a filtration)**.** *In Setting 2.2, let* $\mathfrak{t}$, λ, n *be natural numbers,* $\mathcal{R}$ *a ring,* $\psi = (\psi(s,j))$ *matrices in* $\mathrm{M}_k(\mathcal{R})$*, and* β, β' *families in* $\mathrm{Mon}_{k,n}^L$*. Let* $\mathcal{G}$ *be a family of additive subgroups of* $\mathcal{R}$ *such that* $\mathcal{G}$ *is a real filtration. Let* $\eta_{s,j}(i)$ *be real numbers, for a letter, a natural number and an index, let* ω *be a weight on the variables and* ϵ *a real number, such that*

(i) $|\eta_{s,0}(i)| \le \epsilon$ *for all* s*,* i*, and* $\sum_i \eta_{s,j}(i) = 0$ *for all* s*,* j*;*
(ii) $\omega(i,s) = \eta_{s,m}(i)$ *if* s *is even and* $\omega(i,s) = -\eta_{s,m}(i)$ *if* s *is odd, where* $m = \lambda + \mathrm{dp}_{T,\mathfrak{t}}((i,s))$*;*

(iii) $\psi(s,j)_{ii'} \in \mathcal{G}(\eta_{s,j+1}(i) - \eta_{s,j}(i') - \epsilon)$ *for every letter* s*, every* $j \le \lambda$ *and all indices* i*,* i'*;*

(iv) $0 \le \epsilon$.

Then the (β, β') *entry of* $\mathrm{Fr}_{T,\mathfrak{t},\lambda,n}(\psi)$ *lies in* $\mathcal{G}(\langle\omega,\beta\rangle - L\,n\,k\,(\lambda+2)\,\epsilon)$.

Proof. First, $(\Pi_s^m)_{ii'}$ lies in $\mathcal{G}(\eta_{s,m}(i) - (m+1)\epsilon)$ for $m \le \lambda+1$: for $m=0$ the entries are 0 and 1 and $\eta_{s,0}(i) - \epsilon \le 0$; and $(\psi(s,m)\Pi_s^m)_{ii'} = \sum_l \psi(s,m)_{il}(\Pi_s^m)_{li'}$, where the levels add to $\eta_{s,m+1}(i) - (m+2)\epsilon$. Next, every entry $(B_s)_{ii'}$ lies in $\mathcal{G}(\omega(i,s) - k(\lambda+2)\epsilon)$. For even s this is the first step. For odd s the entry is, up to sign, a minor of Π_s^m without the row i, a sum of products of one entry from each other row; the levels add to $\sum_{l\neq i}\eta_{s,m}(l) - (k-1)(m+1)\epsilon = -\eta_{s,m}(i) - (k-1)(m+1)\epsilon$, by (i). Finally an entry of $\mathrm{Sym}^n(B_s)$ in the row β_s is a sum of products of n entries of B_s, of which $\beta_s(i)$ lie in the row i; and the entry of the Kronecker product is the product over the L letters. □

LEAN `TwistingData.frobOperator_mem`

Lemma 8.3 (conjugation and Frobenius modulo p)**.** *In Setting 2.2, let* γ *be an element of* $\mathrm{GL}_k(W)$*,* s *a letter,* j *a natural number,* G *a matrix in* $\mathrm{M}_k(\mathcal{O})$ *and* i*,* i' *indices. Write* $G^{(j)}$ *for the matrix of the* P_T^j*-th powers of the entries of* G*. Then* p *divides*

$$\Big(\mathrm{cj}_{T,\gamma,s}\big((\mathrm{cj}_{T,\gamma^{-1},s-j}(G))^{(j)}\big)\Big)_{ii'} - (G_{ii'})^{P_T^j}.$$

Proof. Modulo p the map $\pi \mapsto \pi^{P_T^j}$ of $\mathcal{O}$ is a ring homomorphism, so it commutes with products of matrices; and it sends $\iota_{s-j}(\upsilon)$ to $\iota_s(\upsilon)$, by Lemma 3.1(a). Hence $(\iota_{s-j}(\gamma^{-1})\,G\,\iota_{s-j}(\gamma))^{(j)} \equiv \iota_s(\gamma^{-1})\,G^{(j)}\,\iota_s(\gamma)$ modulo p. □

LEAN `TwistingData.p_dvd_cj_frobenius_sub`

Proposition 8.4 (exponents of the Frobenius operator track the excess)**.** *In Setting 2.2, let* i_0*,* i_1 *be indices with* $i_0+1 = i_1$*, let* s_0 *be a letter, and let* λ*,* n *be natural numbers with* $L\,n\,k\,(\lambda+2) \le P_T^\lambda$ *and* $\lambda \le L$*. Let* γ *be an element of* $\mathrm{GL}_k(W)$*, let* T' *be the twisting data* $\chi_* T$ *for the inclusion* χ *of* $\mathcal{O}$ *in the polynomial ring in the generic variables* $x_{s,i,i'}$*, and suppose that* ψ *is given by*

$$\psi(s,j) = \mathrm{cj}_{T',\gamma,s}\Big((\mathrm{cj}_{T',\gamma^{-1},s-j}(X_{s-j}))^{(j)}\Big)$$

for every letter s *and every natural number* j*, in the notation of Lemma 8.3. Let* c *be a natural number,* β, β' *families, and* ν *an exponent on the generic variables, with parts* ν_s *on the variables of the letter* s*. With* rw *and* cw *as in Proposition 7.3 for the function* $\omega_0 = \mathrm{iw}_{T,\lambda}^{i_0,i_1}(\cdot)$ *on the indices, suppose that* $\mathrm{rw}(\nu_s) = \mathrm{cw}(\nu_s)$ *for every letter* $s \neq s_0$*, and that*

$$2c+1 < \big|\langle \mathrm{ex}_{T,s_0+\lambda}^{i_0,i_1}(\cdot), \beta\rangle - \mathrm{rw}(\nu_{s_0})\big|.$$

Then ϖ^c *divides the coefficient of* x^ν *in the* (β,β') *entry of* $\mathrm{Fr}_{T,i_1,\lambda,n}(\psi)$.

Proof. Let $\mathrm{sg} = \pm 1$ be the sign of the difference in the hypothesis, and put

$$\mathrm{a}_m(i) = \omega_0(i)\cdot\tfrac{\mathrm{sg}}{2}\cdot P_T^m/q_T; \qquad \text{so} \quad |\mathrm{a}_m(i)| \le \tfrac{1}{2}P_T^{-\lambda} \ \text{ for } m \le L, \qquad \sum_i \mathrm{a}_m(i) = 0.$$

Give the generic variable $x_{s,i,i'}$ the weight $\mathrm{a}_L(i)$ if $s = s_0$, and $\mathrm{a}_{[s-s_0]}(i) - \mathrm{a}_{[s-s_0]}(i')$ otherwise, and let $\mathcal{G}$ be the corresponding filtration $\mathrm{Gs}_{\mathrm{ad}_{\varpi^{(\cdot)}},\cdot}(\cdot)$ of the polynomial

ring. The weight of x^ν is then $\frac{\mathrm{sg}}{2}\mathrm{rw}(\nu_{s_0})$, the other letters contributing multiples of $\mathrm{rw}(\nu_s)-\mathrm{cw}(\nu_s)=0$. We apply Lemma 8.2, for $\mathfrak{t}=i_1$, with

$$\eta_{s,j}(i)=\mathrm{a}_{j+[s-j-s_0]}(i),\qquad \omega=\tfrac{\mathrm{sg}}{2}\,\mathrm{ex}^{i_0,i_1}_{T,s_0+\lambda}(\cdot),\qquad \epsilon=\tfrac{1}{2}P_T^{-\lambda}.$$

Condition (i) holds by the two properties of a_m. Condition (ii) is the definition of the excess weight at the letter $s_0+\lambda$, read at the two root variables of each letter, using $i_0<i_1$: these are the variables (i_1,s) and (i_0,s), of which the deep one for the threshold i_1 is the root variable $\mathrm{rt}_{T,s}(i_0,i_1)$. For condition (iii) let $j\le\lambda$. By Lemma 8.3 for T', the entry $\psi(s,j)_{ii'}$ is $x^{P_T^j}_{s-j,i,i'}$ plus p times a polynomial; and it is homogeneous of degree P_T^j in the variables of the letter $s-j$. The weights of these variables are at most $P_T^{-\lambda}$ in absolute value, so every monomial of the entry has weight within $2P_T^{j-\lambda}\le 2$ of the weight of the leading one; as $p=\varpi^2$, the entry lies in $\mathcal{G}$ at the level of its leading monomial. That level is P_T^j times the weight of $x_{s-j,i,i'}$, which is $\eta_{s,j+1}(i)-\eta_{s,j}(i')$ if $s-j\ne s_0$ and $\eta_{s,j+1}(i)-\eta_{s,j}(i')+\mathrm{a}_j(i')$ if $s-j=s_0$; and $|\mathrm{a}_j(i')|\le\epsilon$. The lemma gives the level $\frac{\mathrm{sg}}{2}\langle \mathrm{ex}^{i_0,i_1}_{T,s_0+\lambda}(\cdot),\beta\rangle - L\,n\,k\,(\lambda+2)\epsilon$ for the entry, where the last term is at most $\frac12$ by hypothesis. So the coefficient of x^ν is divisible by ϖ to a power that is at least $\frac12\big|\langle \mathrm{ex}^{i_0,i_1}_{T,s_0+\lambda}(\cdot),\beta\rangle-\mathrm{rw}(\nu_{s_0})\big|-\frac12>c$. □

Lemma 8.5 (degrees in the Frobenius operator)**.** *In Setting 2.2, let* $\mathfrak{t}$, λ, n *be natural numbers,* β,β' *families, and* ν *an exponent on the generic variables. If the coefficient of* x^ν *in the* (β,β') *entry of* $\mathrm{Fr}_{T,\mathfrak{t},\lambda,n}(X^{\mathrm{Fr}}_T(\cdot,\cdot))$ *is not zero, then for every letter* s' *the part of* ν *on the variables of* s' *has degree at most* $L\,n\,k\,(\lambda+2)\,P_T^\lambda$.

Proof. The entries of $X^{\mathrm{Fr}}_T(s,j)$ with $j\le\lambda$ have degree at most P_T^λ; those of the products Π_s^m, $m\le\lambda+1$, and of their adjugates have degree at most $k(\lambda+1)P_T^\lambda$; an entry of the n-th symmetric power has n times that degree at most, and an entry of the Kronecker product over L letters L times as much. □

LEAN `TwistingData.degree_le_of_coeff_frobOperator` · the formal proof is Lemma 8.2 for a filtration that records the degree in the variables of one letter

Lemma 8.6 (products of linear forms)**.** *Let* $\mathcal{S}$ *be a finite set,* $\mathcal{V}$ *a set and* $\mathcal{O}$ *a ring. There is a map, linear in each argument, that sends a family* $(\mathcal{L}_\mathfrak{s})_{\mathfrak{s}\in\mathcal{S}}$ *of* $\mathcal{O}$*-linear forms on* $\mathcal{O}[x_\mathcal{V}]$ *to an* $\mathcal{O}$*-linear form* $\bigotimes_\mathfrak{s}\mathcal{L}_\mathfrak{s}$ *on the polynomial ring in the variables* $x_{\mathfrak{s},v}$*, such that* $(\bigotimes_\mathfrak{s}\mathcal{L}_\mathfrak{s})(\prod_\mathfrak{s}\Phi_\mathfrak{s})=\prod_\mathfrak{s}\mathcal{L}_\mathfrak{s}(\Phi_\mathfrak{s})$ *whenever each* $\Phi_\mathfrak{s}$ *is a polynomial in the variables* $x_{\mathfrak{s},v}$*,* $v\in\mathcal{V}$*, read as a polynomial in* $\mathcal{O}[x_\mathcal{V}]$.

Proof. Define the form on a monomial x^ν, with parts $\nu_\mathfrak{s}$, as $\prod_\mathfrak{s}\mathcal{L}_\mathfrak{s}(x^{\nu_\mathfrak{s}})$, and extend linearly. □

LEAN `exists_tensor_dual`

Proof of Theorem 4. Write $q=q_T=p^{oL}$. The hypotheses give

$$n_0+k<q\quad\text{for}\quad n_0=L\,n\,k\,(\lambda+2)\,P_T^\lambda,\qquad n<q,\qquad L\,n\,k\,(\lambda+2)\le P_T^\lambda,\quad(12)$$

because $(L\,n\,k\,(\lambda+2)+n+k+1)\,P_T^\lambda\le P_T^{2\lambda}=q$.

The diagonal form. Let w_0 be the function of Lemma 7.2 for the k indices as variables, the prime p and the exponent oL, and put $w(\beta)=\prod_s w_0(\beta_s)$. As $n<q$, each $w_0(\beta_s)$ divides $p^{k\,oL}$; choose $w'(\beta)$ with $w(\beta)\,w'(\beta)=p^{k\,oL\cdot L}$. Property (iii) of the theorem is

Lemma 7.2(ii) for each letter, since $\rho_{T,n}(\gamma)_{\beta',\beta} = \prod_s \mathrm{Sym}^n(\gamma_{T,s})_{\beta'_s,\beta_s}$ and the letter matrices of γ^{T} are the transposes of those of γ.

The operator. Let Fr be the matrix $\mathrm{Fr}_{T,i_1,\lambda,n}(X_T^{\mathrm{Fr}}(\cdot,\cdot))$, with entries in the polynomial ring in the generic variables. For a family $\mathcal{L} = (\mathcal{L}_s)_s$ of $\mathcal{O}$-linear forms on the polynomials in one generic matrix let $Z(\mathcal{L})$ be the matrix over $\mathcal{O}$ obtained by applying the form $\bigotimes_s \mathcal{L}_s$ of Lemma 8.6 to the entries of Fr; it is linear in each $\mathcal{L}_s$.

The means. For every letter s let $\mathcal{M}_s^+$ and $\mathcal{M}_s^-$ be the forms of Proposition 7.3 for the homomorphism ι_s, the labelling $\tau_{k,i_1}(\cdot)$, the degree n_0, the prime p with the exponent oL, the function $\omega_0 = \mathrm{iw}_{T,\lambda}^{i_0,i_1}(\cdot)$, and the set Ω of all real numbers, respectively of the real numbers greater than $h-(2c+1)$; the hypotheses hold by (12). Put $\mathcal{L}_s^\circ = \mathcal{M}_s^+ - \mathcal{M}_s^-$ and

$$Z = Z(\mathcal{L}^\circ)\cdot \mathrm{diag}(w'(\beta))_\beta.$$

By (a), (b), (c) of the proposition, $\mathcal{L}_s^\circ$ is invariant under $\mathrm{cs}_{\iota_s}(\gamma)$ for γ in the Levi subgroup, and $\mathcal{L}_s^\circ(x^\alpha) = 0$ unless $\mathrm{rw}(\alpha) = \mathrm{cw}(\alpha) \le h-(2c+1)$.

A criterion. Let s_0 be a letter, γ an element of $\mathrm{Lev}_{\tau_{k,i_1}(\cdot)}(W)$, and $\mathcal{L}$, $\mathcal{L}'$ families of forms with $\mathcal{L}'_s = \mathcal{L}_s \circ \mathrm{cs}_{\iota_s}(\gamma)$ for every letter. Let F_1, F_2 be forms. Suppose that for every family β at which the row vector $F_1^{\mathsf{T}}\rho_{T,n}(\gamma^{-1})$ has a coordinate not divisible by ϖ^c, and for every exponent ν on the generic variables, either $\prod_s \mathcal{L}_s(x^{\nu_s}) = 0$, or the two hypotheses of Proposition 8.4 hold for s_0, β and ν. Then ϖ^c divides $F_1^{\mathsf{T}} Z(\mathcal{L}')F_2$. Indeed, $\bigotimes_s \mathcal{L}'_s$ is $\bigotimes_s \mathcal{L}_s$ after the substitution of $\iota_s(\gamma^{-1})X_s\iota_s(\gamma)$ for each X_s. By Lemma 8.1, for the twisting data T' and the substitution as the ring homomorphism, the substituted matrix Fr is $\rho_{T,n}(\gamma^{-1})\cdot \mathrm{Fr}_{T,i_1,\lambda,n}(\psi)\cdot\rho_{T,n}(\gamma)$ with ψ as in Proposition 8.4; the constant matrices pass through the linear form. So

$$F_1^{\mathsf{T}} Z(\mathcal{L}')F_2 = \sum_{\beta,\beta'} (F_1^{\mathsf{T}}\rho_{T,n}(\gamma^{-1}))(\beta)\cdot\Big(\sum_\nu \mathrm{cf}_\nu \prod_s \mathcal{L}_s(x^{\nu_s})\Big)\cdot(\rho_{T,n}(\gamma)F_2)(\beta'),$$

with cf_ν the coefficient of x^ν in the (β,β') entry of $\mathrm{Fr}_{T,i_1,\lambda,n}(\psi)$, and every term is divisible by ϖ^c, by the hypothesis or by Proposition 8.4.

Property (i). Let F be a form, γ in the Levi subgroup, and β a family whose excess at some letter s_1 exceeds h. The coordinate $(\rho_{T,n}(\gamma)ZF)(\beta)$ is $F_1^{\mathsf{T}}Z(\mathcal{L}^\circ)F_2$ for F_1^{T} the β-th row of $\rho_{T,n}(\gamma)$ and $F_2 = w'F$. Apply the criterion with $\mathcal{L} = \mathcal{L}' = \mathcal{L}^\circ$ and $s_0 = s_1 - \lambda$. The row vector $F_1^{\mathsf{T}}\rho_{T,n}(\gamma^{-1})$ is the β-th unit vector. If $\prod_s \mathcal{L}_s^\circ(x^{\nu_s}) \neq 0$, then every ν_s has equal row and column weights, at most $h-(2c+1)$, and the excess of β at $s_0+\lambda$ exceeds $\mathrm{rw}(\nu_{s_0})$ by more than $2c+1$.

Property (ii). Let F' lie in $\mathrm{Ex}_{T,n}^{i_0,i_1}(\varpi^c\mathcal{O}; h-(4c+2))$, let F be a form, and put $\mathrm{bil}(\mathcal{L}) = (wF')^{\mathsf{T}}Z(\mathcal{L})(w'F)$, with the products wF' and $w'F$ taken coordinate by coordinate. The quantity of (ii) is $\mathrm{bil}(\mathcal{L}^\circ)$ less $p^{(k+k^2)oL\cdot L}\sum_\beta F'(\beta)F(\beta)$. Expanding in each letter, $\mathrm{bil}(\mathcal{L}^\circ)$ is the sum, over the subsets $\mathcal{S}$ of the letters, of $\mathrm{bil}(\mathcal{L}^{\mathcal{S}})$ with $\mathcal{L}_s^{\mathcal{S}} = -\mathcal{M}_s^-$ for s in $\mathcal{S}$ and $\mathcal{L}_s^{\mathcal{S}} = \mathcal{M}_s^+$ otherwise.

For the empty subset: by Lemma 8.5 and (c), $\mathcal{M}_s^+$ takes at every monomial that occurs in Fr the value $p^{k^2 oL}$ times its value at the identity; and Fr with all generic matrices equal to the identity is the identity matrix. So $Z(\mathcal{M}^+) = p^{k^2 oL\cdot L}\cdot 1$, and $\mathrm{bil}(\mathcal{M}^+) = p^{k^2 oL\cdot L}\sum_\beta w(\beta)w'(\beta)F'(\beta)F(\beta)$, which is the term subtracted.

For a nonempty subset choose s_0 in it. By (d), $\mathcal{M}^-_{s_0}$ is a combination of forms $\mathcal{L}_0 \circ \mathrm{cs}_{\iota_{s_0}}(\gamma)$ with γ in the Levi subgroup and $\mathcal{L}_0$ vanishing at the x^α with $\mathrm{rw}(\alpha) \le h-(2c+1)$. So it suffices that ϖ^c divides $\mathrm{bil}(\mathcal{L}')$ when $\mathcal{L}'_{s_0} = \mathcal{L}_0 \circ \mathrm{cs}_{\iota_{s_0}}(\gamma)$ and $\mathcal{L}'_s = \mathcal{L}^{\mathcal{S}}_s$ for $s \neq s_0$. Apply the criterion with $\mathcal{L}_{s_0} = \mathcal{L}_0$, $\mathcal{L}_s = \mathcal{L}'_s$ otherwise, which is allowed by the invariance (a), with $F_1 = wF'$ and $F_2 = w'F$. By property (iii), $((wF')^{\mathsf{T}}\rho_{T,n}(\gamma^{-1}))(\beta) = w(\beta)\cdot(\rho_{T,n}((\gamma^{-1})^{\mathsf{T}})F')(\beta)$, and $(\gamma^{-1})^{\mathsf{T}}$ lies in the Levi subgroup; so, by the choice of F', this coordinate is divisible by ϖ^c unless the excess of β is at most $h-(4c+2)$ at every letter. For such β, and ν with $\prod_s \mathcal{L}_s(x^{\nu_s}) \neq 0$: the parts ν_s, $s \neq s_0$, have equal row and column weights by (b), and $\mathrm{rw}(\nu_{s_0}) > h-(2c+1)$, which exceeds the excess of β at $s_0+\lambda$ by more than $2c+1$. □

9 Elementary divisors

In this section $\mathcal{O}$ is a valuation domain, with maximal ideal $\mathfrak{m}$, and $\bar{T} = \mathrm{res}_* T$ is the twisting data over the residue field $\mathcal{O}/\mathfrak{m}$ obtained from T by the residue map $\mathrm{res}\colon \mathcal{O} \to \mathcal{O}/\mathfrak{m}$. For a finite set $\mathcal{X}$ a vector in $\mathcal{O}^{\mathcal{X}\times \mathrm{Mon}^L_{k,n}}$ has the *blocks* $F(\mathfrak{x},\cdot)$, forms in $\mathcal{O}^{\mathrm{Mon}^L_{k,n}}$.

Lemma 9.1 (independent columns)**.** *In Setting 2.2, let $\mathcal{O}$ be a valuation domain, n a natural number, $\mathcal{X}$ a finite set and $\mathcal{N}$ a set. Let A be a matrix over $\mathcal{O}$ with rows indexed by $\mathcal{X}\times\mathrm{Mon}^L_{k,n}$ and columns by $\mathcal{N}$, and A' a matrix with rows indexed by $\mathcal{N}$ and columns by $\mathcal{X}\times\mathrm{Mon}^L_{k,n}$. Let $\mathcal{S}$ be a finite subset of $\mathcal{N}$, τ a labelling and $\mathcal{B}$ a subset of $\mathrm{Mon}^L_{k,n}$. Suppose that $(A'A)_{l,l'}$ is 1 if $l=l'$ and 0 otherwise, for every l' in $\mathcal{S}$ and every l in $\mathcal{N}$, and that for every l' in $\mathcal{S}$ every block of the column l' of A lies in $\mathrm{Tr}_{T,n}(\tau;\mathfrak{m},\mathcal{B})$. Then*

$$\#\mathcal{S} \;\le\; \#\mathcal{X}\cdot\dim_{\mathcal{O}/\mathfrak{m}}\mathrm{Tr}_{\bar{T},n}(\tau;0,\mathcal{B}).$$

Proof. Reduce the columns $l' \in \mathcal{S}$ of A modulo $\mathfrak{m}$. Their blocks lie in $\mathrm{Tr}_{\bar{T},n}(\tau;0,\mathcal{B})$, by Lemma 3.1(d); and they are linearly independent over $\mathcal{O}/\mathfrak{m}$, because the reduction of A' recovers the coefficients of a combination of them. □

LEAN `TwistingData.card_le_finrank_translatesIn`

Proposition 9.2 (two matrices that pair almost perfectly)**.** *In Setting 2.2, let $\mathcal{O}$ be a valuation domain, n a natural number, and $\mathcal{X}$, $\mathcal{N}$ finite sets. Let A and B be matrices over $\mathcal{O}$ with rows indexed by $\mathcal{X}\times\mathrm{Mon}^L_{k,n}$ and columns by $\mathcal{N}$, and let A' and C be matrices with rows indexed by $\mathcal{N}$ and columns by $\mathcal{X}\times\mathrm{Mon}^L_{k,n}$. Let π_1, π_2, π_0 be elements of $\mathcal{O}$, τ a labelling and $\mathcal{B}$ a subset of $\mathrm{Mon}^L_{k,n}$. Suppose that*

(i) $A'A = 1$;
(ii) π_0 *is not a unit;*
(iii) $\pi_1\pi_0$ *divides every entry of* $CB - \pi_1\cdot 1$;
(iv) *whenever* $AF_1 - BF_2 = \pi_1\pi_0 F$ *for vectors* F_1, F_2 *in* $\mathcal{O}^{\mathcal{N}}$ *and* F *in* $\mathcal{O}^{\mathcal{X}\times\mathrm{Mon}^L_{k,n}}$, *every block of* F *lies in* $\mathrm{Tr}_{T,n}(\tau;\mathfrak{m},\mathcal{B})$.

Then there is a natural number l with

$$\#\mathcal{N}+l \;\le\; \#\mathcal{X}\cdot\dim_{\mathcal{O}/\mathfrak{m}}\mathrm{Tr}_{\bar{T},n}(\tau;0,\mathcal{B}) \qquad \text{and} \qquad [\mathcal{O}^{\mathcal{N}}:CA(\mathcal{O}^{\mathcal{N}})+\pi_2\,\mathcal{O}^{\mathcal{N}}]\;\big|\;\pi_1^{\#\mathcal{N}}\pi_2^{l}.$$

Proof. Write $\mathcal{Y}=\mathcal{X}\times\mathrm{Mon}_{k,n}^{L}$. By Input 2(b), for the valuation pair $(\mathcal{O},\mathcal{O})$, there are invertible matrices U, U' over $\mathcal{O}$ and elements ε_y of $\mathcal{O}$, $y\in\mathcal{Y}$, with

$$(AA'B-B)\,A'=U\,\mathrm{diag}(\varepsilon_y)\,U'. \tag{13}$$

Multiplying by A' on the left and using (i) gives $A'U\,\mathrm{diag}(\varepsilon_y)=0$; so the column y of $A'U$ is zero whenever $\varepsilon_y\neq 0$. Let $\mathcal{Y}_0$ be the set of the y with $\varepsilon_y\neq 0$ and ε_y dividing $\pi_1\pi_0$, and $l=\#\mathcal{Y}_0$.

The inequality. Apply Lemma 9.1 to the matrix $(A\ U)$, with columns indexed by the disjoint union of $\mathcal{N}$ and $\mathcal{Y}$, to the matrix with the rows of A' above those of $U^{-1}-U^{-1}AA'$, and to the columns in $\mathcal{N}$ and in $\mathcal{Y}_0$. The product of the two matrices has the blocks 1, $A'U$, 0 and $1-U^{-1}AA'U$; its columns in $\mathcal{N}$ and in $\mathcal{Y}_0$ are unit vectors, by the remark on $A'U$. The blocks of a column $Ae_{l'}$ lie in $\mathrm{Tr}_{T,n}(\tau;\mathfrak{m},\mathcal{B})$ by (iv) with $F_1=\pi_1\pi_0e_{l'}$ and $F_2=0$. For y in $\mathcal{Y}_0$ write $\pi_1\pi_0=\varepsilon_y\pi'$; by (13), with $F_2=\pi'A'U'^{-1}e_y$, we have $A(A'BF_2)-BF_2=\pi_1\pi_0\,Ue_y$, and (iv) applies to the column Ue_y.

The index. For every y one of $\pi_1\pi_0$, ε_y divides the other; choose ε'_y with $\pi_1\pi_0\varepsilon'_y=\varepsilon_y$, or with $\varepsilon_y\varepsilon'_y=\pi_1\pi_0$ when the former is impossible. Put $C_1=CU\,\mathrm{diag}(\pi_1\pi_0\varepsilon'_y-\varepsilon_y)$; its column y is zero for y outside $\mathcal{Y}_0$. Write $CB-\pi_1=\pi_1\pi_0C_0$ by (iii). Using (13) and (i),

$$C_1U'A+CAA'B=\pi_1\pi_0\,CU\,\mathrm{diag}(\varepsilon'_y)U'A+CB=\pi_1(1+\pi_0\,(C_0+CU\,\mathrm{diag}(\varepsilon'_y)U'A)).$$

The determinant of the last bracket is congruent to 1 modulo π_0, hence a unit by (ii); so the determinant of the left side divides $\pi_1^{\#\mathcal{N}}$, and its image lies in $C_1(\mathcal{O}^{\mathcal{Y}})+CA(\mathcal{O}^{\mathcal{N}})$. By Input 1(a), $[\mathcal{O}^{\mathcal{N}}:C_1(\mathcal{O}^{\mathcal{Y}})+CA(\mathcal{O}^{\mathcal{N}})+\pi_2\mathcal{O}^{\mathcal{N}}]\;\big|\;\pi_1^{\#\mathcal{N}}$. The diagonal matrix on $\mathcal{O}^{\mathcal{Y}}$ with the entries π_2 at $\mathcal{Y}_0$ and 1 elsewhere has determinant π_2^{l}, and C_1 maps its image into $\pi_2\mathcal{O}^{\mathcal{N}}$. By Input 1(a) and (c), for the map C_1, $[C_1(\mathcal{O}^{\mathcal{Y}})+CA(\mathcal{O}^{\mathcal{N}})+\pi_2\mathcal{O}^{\mathcal{N}}:CA(\mathcal{O}^{\mathcal{N}})+\pi_2\mathcal{O}^{\mathcal{N}}]\;\big|\;\pi_2^{l}$, and Input 1(b) gives the claim. □

LEAN `TwistingData.of_pairing` · `TwistingData.card_le_finrank_translatesIn` · `IsValuationPair.smith_normal_form` · `IndexDvd.of_det_dvd` · `IndexDvd.map` · `IndexDvd.trans`

Proposition 9.3 (the depth factorisation)**.** *In Setting 2.2, let $\mathcal{O}$ be a valuation domain of characteristic zero, c and n natural numbers, i_0, i_1 indices with $i_0<i_1$, and j_0 a natural number with $\mathrm{depth}_{T,i_1}^{k,n}(\beta)\le j_0$ for every family β. Let $\mathcal{X}$ and $\mathcal{E}$ be finite sets, $\mathrm{pt}\colon\mathcal{E}\to\mathcal{X}$ a map and $(\gamma_{\mathfrak{e}})_{\mathfrak{e}\in\mathcal{E}}$ elements of $\mathrm{GL}_k(W)$ such that the map $\mathfrak{e}\mapsto(\mathrm{pt}(\mathfrak{e}),\gamma_{\mathfrak{e}}^{-1}\mathrm{Par}_{\tau_{k,i_1}(\cdot)}(W))$ from $\mathcal{E}$ to $\mathcal{X}\times\mathrm{GL}_k(W)/\mathrm{Par}_{\tau_{k,i_1}(\cdot)}(W)$ is surjective. Let J be the matrix with rows indexed by $\mathcal{E}\times\mathrm{Mon}_{k,n}^{L}$ and columns by $\mathcal{X}\times\mathrm{Mon}_{k,n}^{L}$ whose entry at $((\mathfrak{e},\beta),(\mathfrak{x},\beta'))$ is $\varpi^{\mathrm{depth}_{T,i_1}^{k,n}(\beta)}\cdot\rho_{T,n}(\gamma_{\mathfrak{e}})_{\beta,\beta'}$ if $\mathrm{pt}(\mathfrak{e})=\mathfrak{x}$, and 0 otherwise. Then there are a matrix A of the shape of J, a square matrix Δ indexed by $\mathcal{X}\times\mathrm{Mon}_{k,n}^{L}$ and a matrix A' of the shape of the transpose of J, all over $\mathcal{O}$, such that:*

(i) $A\Delta=J$;
(ii) $\det\Delta$ *divides* ϖ *to the power* $\#\mathcal{X}\cdot\sum_{j<j_0}\dim_{\mathcal{O}/\mathfrak{m}}\mathrm{Dp}_{\bar{T},i_1}^{k,n}(j)$;

(iii) $A'A = 1$;

(iv) *for every* F *in* $\mathcal{O}^{\mathcal{X}\times \mathrm{Mon}^L_{k,n}}$, *every* $\mathfrak{e}$ *in* $\mathcal{E}$ *and every real number* h *with* $2c \le h$, *the block* $(AF)(\mathfrak{e},\cdot)$ *lies in* $\mathrm{Ex}^{i_0,i_1}_{T,n}(\varpi^c\mathcal{O}; h)$.

Proof. Write $\mathcal{Y} = \mathcal{X}\times \mathrm{Mon}^L_{k,n}$, $\mathrm{Par} = \mathrm{Par}_{\tau_{k,i_1}(\cdot)}(W)$ and $\mathrm{d}(\beta) = \mathrm{depth}^{k,n}_{T,i_1}(\beta)$. So

$$(JF)(\mathfrak{e},\beta) = \varpi^{\mathrm{d}(\beta)}\,(\rho_{T,n}(\gamma_{\mathfrak{e}})F(\mathrm{pt}(\mathfrak{e}),\cdot))(\beta).$$

Step 1: divisibility passes to all translates. Let π in $\mathcal{O}$ divide every coordinate of JF. Then π divides $\varpi^{\mathrm{d}(\beta)}(\rho_{T,n}(\gamma)F(\mathfrak{x},\cdot))(\beta)$ for every $\mathfrak{x}$, every γ in $\mathrm{GL}_k(W)$ and every β. Indeed, choose $\mathfrak{e}$ with $\mathrm{pt}(\mathfrak{e}) = \mathfrak{x}$ and $\gamma' = \gamma\gamma_{\mathfrak{e}}^{-1}$ in Par. For a letter s and indices i, i' such that (i,s) is not deep and (i',s) is deep, for $\mathfrak{t} = i_1$, the entry $(\gamma'_{T,s})_{ii'}$ is divisible by $p = \varpi^2$ (Lemma 3.2). So there are matrices G_s over $\mathcal{O}$ with $\mathrm{diag}(\varpi^{\mathrm{dp}_{T,i_1}((i,s))})_i \cdot \gamma'_{T,s} = G_s \cdot \mathrm{diag}(\varpi^{\mathrm{dp}_{T,i_1}((i,s))})_i$, and by Lemma 3.1(e), $\mathrm{diag}(\varpi^{\mathrm{d}(\beta)})\,\rho_{T,n}(\gamma') = (\bigotimes_s \mathrm{Sym}^n(G_s))\,\mathrm{diag}(\varpi^{\mathrm{d}(\beta)})$. Hence the vector $(\varpi^{\mathrm{d}(\beta)}(\rho_{T,n}(\gamma)F(\mathfrak{x},\cdot))(\beta))_\beta$ is the image of the block $(JF)(\mathfrak{e},\cdot)$ under a matrix over $\mathcal{O}$.

Step 2: the factorisation. The map pt is surjective; a section of it makes $\mathcal{Y}$ a subset of $\mathcal{E}\times\mathrm{Mon}^L_{k,n}$. Input 2(a), for $(\mathcal{O},\mathcal{O})$ and the weights 0, gives an invertible matrix U and a square matrix Δ with $J = U_{\cdot,y}\Delta$. Put $A = U_{\cdot,y}$ and $A' = (U^{-1})_{y,\cdot}$; then (i) and (iii) hold. By Input 2(b), $\Delta = U_1\,\mathrm{diag}(\varepsilon_y)U_2$ with U_1, U_2 invertible over $\mathcal{O}$. The column y of $JU_2^{-1} = AU_1\,\mathrm{diag}(\varepsilon_y)$ is divisible by ε_y; so by Step 1, for all $\mathfrak{x}$, γ, β,

$$\varepsilon_y \ \text{ divides } \ \varpi^{\mathrm{d}(\beta)}\,(\rho_{T,n}(\gamma)\,(U_2^{-1}e_y)(\mathfrak{x},\cdot))(\beta). \tag{14}$$

In particular ε_y divides ϖ^{j_0}: this element is the (y,y) entry of $U_2\cdot\varpi^{j_0}\cdot U_2^{-1}$, a sum of terms each divisible by ε_y, by (14) for $\gamma = 1$ and $\mathrm{d}(\beta)\le j_0$. Choose ε'_y with $\varepsilon_y\varepsilon'_y = \varpi^{j_0}$.

Step 3: the determinant. Up to a unit, $\det\Delta = \prod_y \varepsilon_y$. For each y let m_y be the number of the $j < j_0$ such that ε_y does not divide ϖ^j. These j form an initial segment, and ε_y divides ϖ^{j_0}; so ε_y divides ϖ^{m_y}, and $\sum_y m_y$ is the sum over $j<j_0$ of the number of the y with $\varepsilon_y \nmid \varpi^j$. For a fixed j, apply Lemma 9.1 to the matrices U_2^{-1} and U_2, to these y, the constant labelling 0 and the set $\mathcal{B}$ of the β with $\mathrm{d}(\beta) < j$: if some coordinate in (14) with $\mathrm{d}(\beta)<j$ had a unit as second factor, ε_y would divide ϖ^j. So the number of these y is at most $\#\mathcal{X}\cdot\dim \mathrm{Dp}^{k,n}_{T,i_1}(j)$. This is (ii).

Step 4: the excess condition. Let F, $\mathfrak{e}$ and $h\ge 2c$ be as in (iv), let γ lie in $\mathrm{Lev}_{\tau_{k,i_1}(\cdot)}(W)$ and let β be a family whose excess at a letter s_0 exceeds h. Put $F^\circ = U_2^{-1}\,\mathrm{diag}(\varepsilon'_y)U_1^{-1}F$; then $JF^\circ = \varpi^{j_0}AF$. Let $F_1 = F^\circ(\mathrm{pt}(\mathfrak{e}),\cdot)$. The letter matrices of γ are block diagonal, so $\rho_{T,n}(\gamma)$ commutes with $\mathrm{diag}(\varpi^{\mathrm{d}(\beta)})$, and

$$\varpi^{j_0}\cdot(\rho_{T,n}(\gamma)(AF)(\mathfrak{e},\cdot))(\beta) = \varpi^{\mathrm{d}(\beta)}\cdot(\rho_{T,n}(\gamma\gamma_{\mathfrak{e}})F_1)(\beta).$$

As $\varpi\neq 0$ (Lemma 3.1), we have to show that ϖ^{j_0+c} divides the right side.

Let $\omega = \mathrm{dp}_{T,i_1}(\cdot) - \frac12\mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot)$, a weight on the variables. For a family β' let $\mathrm{ord}(\beta')$ be the largest natural number, at most $\max(\lceil j_0 - \langle\omega,\beta'\rangle\rceil, 0)$, such that $\varpi^{\mathrm{ord}(\beta')}$ divides $(\rho_{T,n}(\gamma')F_1)(\beta')$ for every γ' in $\mathrm{GL}_k(W)$. Choose a family β_0 for which $\theta_0 = \mathrm{ord}(\beta_0) + \langle\omega,\beta_0\rangle$ is least. Then, for every γ' and every β',

$$\varpi \ \text{ to the power } \ \max(\lceil\theta_0 - \langle\omega,\beta'\rangle\rceil, 0) \ \text{ divides } \ (\rho_{T,n}(\gamma')F_1)(\beta'), \tag{15}$$

because the natural number $\mathrm{ord}(\beta')$ is at least $\theta_0 - \langle\omega, \beta'\rangle$. We claim that $\theta_0 \geq j_0$. If $\mathrm{ord}(\beta_0)$ is the bound in its definition, this is clear. Otherwise there is γ_0 such that $\varpi^{\mathrm{ord}(\beta_0)+1}$ does not divide $(\rho_{T,n}(\gamma_0)F_1)(\beta_0)$. On the one hand, Step 1 for F° and $\pi = \varpi^{j_0}$ shows that ϖ^{j_0} divides $\varpi^{\mathrm{d}(\beta_0)}(\rho_{T,n}(\gamma_0)F_1)(\beta_0)$; so $j_0 \leq \mathrm{ord}(\beta_0) + \mathrm{d}(\beta_0)$. On the other hand, Theorem 1 applies to the indices $i_0 \neq i_1$, the letter s_0, the constant labelling 0, the weight ω, the polynomial of the form $\rho_{T,n}(\gamma_0)F_1$, the exponent β_0 and the order $e = \mathrm{ord}(\beta_0)$: its hypothesis on the translates is (15), by Lemma 3.1(c), and the hypothesis on ω holds because of the two root variables of a letter exactly $\mathrm{rt}_{T,s}(i_0, i_1)$ is deep for $\mathfrak{t} = i_1$, so that the difference in question is 1 less half a difference of two excess weights, which lies in $[0.4, 1.6]$ by Lemma 3.3. The theorem gives $\langle \mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot), \beta_0\rangle \leq 0$, that is, $\langle\omega, \beta_0\rangle \geq \mathrm{d}(\beta_0)$; and so $\theta_0 \geq \mathrm{ord}(\beta_0) + \mathrm{d}(\beta_0) \geq j_0$.

Finally, by (15) for $\gamma' = \gamma\gamma_{\mathfrak{e}}$ and β, the coordinate $(\rho_{T,n}(\gamma\gamma_{\mathfrak{e}})F_1)(\beta)$ is divisible by ϖ to a power that is at least $\theta_0 - \langle\omega, \beta\rangle \geq j_0 - \mathrm{d}(\beta) + \frac{1}{2}\langle \mathrm{ex}^{i_0,i_1}_{T,s_0}(\cdot), \beta\rangle > j_0 - \mathrm{d}(\beta) + c$, as the excess of β exceeds $h \geq 2c$. □

Proof of Theorem 5. Notation. Put $\kappa_0 = (k + k^2)\,oL \cdot L$ and $c = 2\kappa_0 + 2$; the seventh size condition reads $6c + 2 \leq y$. Let i_1 be the index $\mathfrak{t}$ and $i_0 = \mathfrak{t} - 1$; they exist because $0 < \mathfrak{t}$ and $2\mathfrak{t} \leq k$. Let j_0 be a bound for the depths $\mathrm{depth}^{k,n}_{T,\mathfrak{t}}(\beta)$. The residue field $\mathcal{O}/\mathfrak{m}$ has characteristic p, as p is not a unit, and $\bar{T}$ satisfies the same size conditions as T; also ϖ is not a unit, and $\varpi \neq 0$. Put $\mathcal{X}' = \mathcal{H} \times \mathcal{X}$, $\mathcal{E}' = \mathcal{H} \times \mathcal{E}$ and $\mathcal{Y} = \mathcal{X}' \times \mathrm{Mon}^L_{k,n}$; then $\#\mathcal{Y} = \#\mathcal{X} \cdot \#\mathcal{I}$, by the bijection $\jmath$. Write $\mathrm{Par} = \mathrm{Par}_{\tau_{k,\mathfrak{t}}(\cdot)}(W)$.

Two factorisations. The map of the hypothesis is an injective map of the finite set $\mathcal{E}$ to itself, hence bijective. So Proposition 9.3 applies, with c, (i_0, i_1), j_0, to the sets $\mathcal{X}'$ and $\mathcal{E}'$ with

$$\mathrm{pt}_1(\mathfrak{h}, \mathfrak{e}) = (\mathfrak{h}, \mathrm{src}(\mathfrak{e})) \ \text{ and the elements } \gamma^{\mathsf{T}}_{\mathfrak{e}}; \qquad \mathrm{pt}_2(\mathfrak{h}, (\mathfrak{x}, \mathfrak{q})) = (\mathfrak{h}, \mathfrak{x}) \ \text{ and the } \tilde{\mathfrak{q}}^{-1}.$$

Let $J_1 = A_1\Delta_1$ and $J_2 = A_2\Delta_2$ be the factorisations, with left inverses A'_1, A'_2.

The projector. Let w and Z be as in Theorem 4 for c, (i_0, i_1), λ and $h = y$; its hypotheses are the fifth and sixth size conditions. On vectors indexed by $\mathcal{E}' \times \mathrm{Mon}^L_{k,n}$ let $\mathbf{u}$ act by $u_{\mathfrak{e}}$ on the coordinate in $\mathcal{H}$, for each $\mathfrak{e}$, let $\mathbf{Z}$ act by Z and $\mathbf{w}$ by $\mathrm{diag}(w(\beta))$ on the coordinate in $\mathrm{Mon}^L_{k,n}$.

The pairing. We apply Proposition 9.2 to the sets $\mathcal{E}'$ (in the place of $\mathcal{X}$) and $\mathcal{Y}$ (in the place of $\mathcal{N}$), the matrices

$$A = A_1, \qquad B = \mathbf{u}^{-1}\mathbf{Z}\,A_2'^{\mathsf{T}}, \qquad A' = A'_1, \qquad C = A_2^{\mathsf{T}}\,\mathbf{u}\,\mathbf{w},$$

the elements $\pi_1 = \varpi^{2\kappa_0} = p^{\kappa_0}$, $\pi_2 = p^e$, $\pi_0 = \varpi$, the labelling $\tau_{k,\mathfrak{t}}(\cdot)$ and the set $\mathcal{B}$ of the families whose excess for (i_0, i_1) exceeds y at some letter; so the module of the conclusion is built from $\mathrm{Ex}^{i_0,i_1}_{\bar{T},n}(0; y)$. Hypotheses (i) and (ii) hold. For (iii): $CB = A_2^{\mathsf{T}}\,\mathbf{w}\mathbf{Z}\,A_2'^{\mathsf{T}}$, so its (y_1, y_2) entry is the sum over $\mathfrak{e}'$ in $\mathcal{E}'$ of $\sum_\beta F'(\beta)w(\beta)(ZF)(\beta)$ for the blocks $F' = (A_2 e_{y_1})(\mathfrak{e}', \cdot)$ and $F = (A_2'^{\mathsf{T}} e_{y_2})(\mathfrak{e}', \cdot)$. By Proposition 9.3(iv), and because $2c \leq y - (4c + 2)$, the block F' lies in

$$\mathrm{Ex}^{i_0,i_1}_{T,n}(\varpi^c\mathcal{O}; y - (4c + 2)).$$

By Theorem 4(ii) the entry is congruent modulo ϖ^{c} to p^{κ_0} times the (y_1, y_2) entry of $A_2^{\mathsf{T}} A_2'^{\mathsf{T}} = 1$; and $\pi_1 \pi_0 = \varpi^{c-1}$. For (iv): if $A_1 F_1 - B F_2 = \varpi^{c-1} F$, then each block of $A_1 F_1$ lies in $\mathrm{Ex}^{i_0,i_1}_{T,n}(\varpi^{c}\mathcal{O}; y)$ by Proposition 9.3(iv), and each block of $B F_2$ is Z applied to a form, so it lies there by Theorem 4(i). Hence, for γ in the Levi subgroup and β in $\mathcal{B}$, ϖ^{c} divides ϖ^{c-1} times the coordinate of the translate of a block of F, and that coordinate lies in $\mathfrak{m}$. The proposition gives a natural number l with

$$\#\mathcal{Y} + l \le \#\mathcal{E}' \cdot \dim_{\mathcal{O}/\mathfrak{m}} \mathrm{Ex}^{i_0,i_1}_{\bar{T},n}(0; y), \qquad [\mathcal{O}^{\mathcal{Y}} : C A_1(\mathcal{O}^{\mathcal{Y}}) + p^{e}\mathcal{O}^{\mathcal{Y}}] \;\big|\; p^{\kappa_0 \#\mathcal{Y} + e l}. \tag{16}$$

The chain. Let $e_0 = \#\mathcal{X}' \cdot \sum_{j<j_0} \dim_{\mathcal{O}/\mathfrak{m}} \mathrm{Dp}^{k,n}_{\bar{T},\mathfrak{t}}(j)$; the determinants of Δ_1 and of Δ_2^{T} divide ϖ^{e_0}. By Input 1(a), $[\mathcal{O}^{\mathcal{Y}} : \Delta_1(\mathcal{O}^{\mathcal{Y}}) + p^{e}\mathcal{O}^{\mathcal{Y}}] \mid \varpi^{e_0}$, and the same for Δ_2^{T}. Input 1(d), used for the endomorphism $C A_1$ with (16) and then for Δ_2^{T}, gives

$$[\mathcal{O}^{\mathcal{Y}} : \Delta_2^{\mathsf{T}} C A_1 \Delta_1(\mathcal{O}^{\mathcal{Y}}) + p^{e}\mathcal{O}^{\mathcal{Y}}] \mid p^{l'}, \qquad l' = e_0 + \kappa_0 \,\#\mathcal{Y} + e\, l,$$

because $\varpi^{2e_0} = p^{e_0}$; and $\Delta_2^{\mathsf{T}} C A_1 \Delta_1 = J_2^{\mathsf{T}}\, \mathbf{u}\, \mathbf{w}\, J_1$.

The exponent. By Theorem 3(b) for $\bar{T}$, $e_0 \le (1+z)\,\#\mathcal{X} \cdot \#\mathcal{J}$. By (16) and Theorem 3(a) for $\bar{T}$, with $h = y$ and the index $\#\mathcal{Q}$ of the parahoric subgroup,

$$l \;\le\; \#\mathcal{H} \cdot \#\mathcal{X} \cdot \left(\#\mathcal{Q} \cdot \dim \mathrm{Ex}^{i_0,i_1}_{\bar{T},n}(0; y) - (\#\mathrm{Mon}_{k,n})^{L}\right) \;\le\; \kappa \cdot \#\mathcal{X} \cdot \#\mathcal{J}.$$

As $1 + \kappa_0 = c/2 \le y$, we get $l' \le (z + \kappa e + y) \cdot \#\mathcal{X} \cdot \#\mathcal{J}$.

The operator. Let r be the isomorphism from $\mathcal{O}^{\mathcal{Y}}$ to $\mathcal{O}^{\mathcal{X}\times\mathcal{J}}$ with

$$(\mathrm{r}G)(\mathfrak{x}, \mathfrak{i}) = G((\mathfrak{h}_{\mathfrak{i}}, \mathfrak{x}), \beta_{\mathfrak{i}}).$$

We claim that, for every G in $\mathcal{O}^{\mathcal{Y}}$,

$$\mathrm{r}\big(J_2^{\mathsf{T}}\, \mathbf{u}\, \mathbf{w}\, J_1\, G\big) = \big(\mathrm{r}(\mathbf{w} G)\big)^{\flat}, \tag{17}$$

with $F \mapsto F^{\flat}$ the operator of the statement. By the definitions of J_1 and J_2, the coordinate of $J_2^{\mathsf{T}}\mathbf{u}\mathbf{w}J_1 G$ at $((\mathfrak{h}, \mathfrak{x}), \beta)$ is

$$\sum_{\mathfrak{q}} \sum_{\mathfrak{h}', \beta', \beta''} \varpi^{2\mathrm{d}(\beta')}\, \rho_{T,n}(\tilde{\mathfrak{q}}^{-1})_{\beta',\beta}\, (u_{(\mathfrak{x},\mathfrak{q})})_{\mathfrak{h},\mathfrak{h}'}\, w(\beta') \cdot \rho_{T,n}(\gamma^{\mathsf{T}}_{(\mathfrak{x},\mathfrak{q})})_{\beta',\beta''}\, G((\mathfrak{h}', \mathrm{src}(\mathfrak{x}, \mathfrak{q})), \beta''),$$

with $\mathrm{d}(\beta')$ the depth. By Theorem 4(iii), $w(\beta')\, \rho_{T,n}(\gamma^{\mathsf{T}})_{\beta',\beta''} = w(\beta'')\, \rho_{T,n}(\gamma)_{\beta'',\beta'}$; with $\varpi^2 = p$ the sum over β' becomes the (β'', β) entry of the matrix $H_{(\mathfrak{x},\mathfrak{q})}$ of the statement, and (17) follows.

Conclusion. By hypothesis $Y(\mathrm{im}\,\Psi) \subseteq \mathrm{im}\,\Psi$, and by (17) the map $\Psi \circ \mathrm{r}$ sends the image of $J_2^{\mathsf{T}}\mathbf{u}\mathbf{w}J_1$ into $Y(\mathrm{im}\,\Psi)$. Input 1(c), for the map $\Psi \circ \mathrm{r}$, carries the index statement of the chain to $[\mathrm{im}\,\Psi : Y(\mathrm{im}\,\Psi) + p^{e}\,\mathrm{im}\,\Psi] \mid p^{l'}$. □

10 Where the results are used

Theorem 5 is used once, in the unit of the columns (unit 145), for the operator attached to a marked prime of the field of the data. There W is the valuation ring of that field at the prime; the letters are the infinite places of a certain class (the tops) that induce the prime or its complex conjugate, with the embeddings of these places, or their composites with complex conjugation, as the maps ι_s; $\mathcal{O}$ is the ring of the complex numbers that are integral for an embedding into a p-adic field; k is the rank of the columns, n the number that the handout calls $a(D)$, and the threshold $\mathfrak{t}$ the least natural number such that p to that power is at least the number of lifts of the data; and the module is that of the integral columns. The size conditions are verified in the same unit. The result enters Theorem A of the write-up through the index statement (b) of that theorem: it is the price, in index, of regaining at some primes the divisibility that the theta lifts lose there. Theorems 1 to 4 and the other results of the unit are used only inside it.

11 Notes on the formal text

1. *The three declarations without a name.* The unit has three instances: that the family $\mathrm{ad}_{\varpi}(\cdot)$ has the three properties of Definition 2.7(a), that $\mathrm{Gs}_{\mathcal{F},\omega}(\cdot)$ has them when $\mathcal{F}$ has, and that a parahoric subgroup has finite index when the residue field is finite. The first two are stated after Definition 2.7; the third is used silently wherever an index of a parahoric subgroup is counted.

2. *Letters.* The formal text writes N for the number of letters (here L, the letter N being kept in this write-up for the level), r for the threshold (here $\mathfrak{t}$), ℓ for $L/2$ (here λ), a, a' for the pair of indices (here i_0, i_1), i for the base letter (here s_0), w for ϖ, o_0 for o, R, O, K for the ring of the data, g, h, u for group elements (here γ), c, x for weights (here ω), P, v, D, Ω for ϱ, par, δ, $\mathcal{C}$ in the statements on cones, ν, β for the points ξ, η there, Q, M, R, β and a, z, w for the matrices A, B, A', C and the elements π_1, π_2, π_0 of Proposition 9.2, Q, d, R, s, g, x for A, Δ, A', pt, γ, j_0 of Proposition 9.3, b, θ for w, h of Theorem 4, κ, P, D, f, x for $\mathcal{M}$, Ω, n_0, e, ω of Proposition 7.3, and f, M, J, m, c for Ψ, V, $\jmath$, e, $\mathfrak{x}$ of Theorem 5.

3. *Arguments that a reading by program adds.* In seventeen declarations of the unit a reading of the text by program lists as an argument a name that the declaration binds itself, because a variable of the same name is declared earlier in the file: the group element in the letter matrices, in the action, in the matrix on forms and in the conditions on forms; the base letter in the excess condition; the letter in the Frobenius operator and in three lemmas on it; the matrices and the exponent in Proposition 9.3; a family in Theorem 4; the point of $\mathcal{X}$ in the formula of Theorem 5; the element ϖ in Theorem 1, where the statement mentions only the component of T; the name under which the degree is passed on in the depth; and the index of the cone of Definition 2.8(d), listed twice. This note states every declaration with the arguments that its uses in the artifact show: the depth has five, the conditions on forms five and six, the Frobenius operator five. Lean was not asked.

4. *An argument that the reading by program misses.* In Proposition 5.2 the formal statement names the determinant by a local definition before the equation, and the reading by program stops there; so it does not see that the statement depends

on k. Lean takes k as the first, implicit, argument: the proof of Theorem 2 applies the proposition with eight arguments, of which k is the first.

5. *Counting an infinite set.* The number of elements of the residue field in Lemma 4.1, Lemma 7.1 and Proposition 7.3 is, in the formal text, a natural number that is 0 for an infinite field. For twisting data the field is finite, by the last condition of Definition 2.1.

6. *Hypotheses that are not used.* Setting 2.2 asks for $L \geq 1$. Some elementary lemmas of the unit do not ask for it (parts of Lemma 3.1, Lemma 8.3); nothing is lost, there being no twisting data for $L = 0$. Lemma 3.4, Lemma 6.2, Lemma 6.3 and Definition 2.8(d) are stated in the formal text for data over a field, which their proofs do not use. Of the ten size conditions, Theorem 3(a) uses the third, fourth, eighth and ninth, Theorem 3(b) the first, second, fourth, fifth, sixth, ninth and tenth, Theorem 4 the fifth and sixth; Theorem 5 uses all.

7. *Arguments with default values.* In Lemma 4.2 the second homomorphism is, by default, the first, and hypotheses (ii) and (iii) are then discharged by Lean; hypothesis (iv) of Lemma 8.2 and the weights of the Hermite form have defaults as well.

8. *Definitions written out.* The formal text defines the cone of Definition 2.8(c) through the step of (a); the two inequalities written there are that definition unfolded. Volumes are taken as real numbers. In Theorem 5 the formal statement takes an enumeration of the cosets as an argument and the chosen representative of a coset from the library; the module on which Ψ is defined is written as a module of functions of two arguments.

9. *The last line of Theorem 5.* It is the index divisibility of Input 1: for every finite family in the image of Ψ a square matrix with determinant dividing p^l moves it into $Y(\operatorname{im}\Psi) + p^e \operatorname{im}\Psi$. Nothing is assumed about torsion in V, and the residue field of $\mathcal{O}$, over which the dimensions of Theorem 3 are taken in the proof, is not the residue field of W.

10. *The constant of Theorem 5.* The proof fixes $c = 2(k + k^2)oL \cdot L + 2$, the number in the seventh size condition; an unrelated variable of the same name is in scope in the file.

11. *Assemblies.* Theorem 5 assembles Theorems 3 and 4 and Propositions 9.2 and 9.3; Theorem 3(a) assembles Theorem 2, Proposition 6.5 and Lemmas 6.1 to 6.4. Their own content is the bookkeeping written out in their proofs.

12. *Sources named by the artifact.* The headers of three files of the unit call parts of the argument known and name related work. This note has not compared any of it; the titles and years are those of the headers. For the root lemma: counts of zeros against degree, after Stepanov, and E. Bombieri, *Counting points on curves over finite fields*, Sém. Bourbaki 430 (1973); Ghate and Jana, *Modular representations of* $\mathrm{GL}_2(\mathbb{F}_q)$ *using calculus* (2025); Imai and Koskivirta, *Automorphic vector bundles on the stack of G-zips* (2021). For the dimension bounds: volumes of interlacing regions, Frobenius amplification and counting by leading terms along flags; Forrester and Zhang, *Corank-1 projections and the randomised Horn problem* (2021), after Dixon (1905) and Anderson (1991); Bombieri, as above; Okounkov, *Brunn–Minkowski inequality for multiplicities* (1996). For the

projector: the Schur algebra as the dual of the polynomials in a generic matrix, and truncation by weights; Benson and Doty, *Schur–Weyl duality over finite fields* (2009); J. A. Green, *Polynomial representations of* GL_n (1980); Donkin, *On Schur algebras and related algebras I* (1986). The file of Input 3 names the two papers cited after the Inputs.

How this note was written. From the dossier of the unit: its 78 statement readings and its structured proofs; the program check of the dossier covered 320 leaf steps of 32 proofs. A second reader compared all readings with the Lean text and sampled every proof; the corrections of that reading are followed here: in Proposition 9.3 the root lemma is applied with the order $\mathrm{ord}(\beta_0)$ and the inequality $j_0 \le \mathrm{ord}(\beta_0) + \mathrm{d}(\beta_0)$ is not strict, the numbers m_y are counts and not valuations, the first factorisation in the proof of Theorem 5 uses the transposed elements, the divisibility in the proof of Theorem 4 rests on the condition on coefficients and not on invariance alone, and Theorem 2 is an identity for every real $\varrho > 1$. I read the eight files of the unit completely, and in the background library the definitions of the conventions and the statements of the Inputs; I did not read the proofs of the Inputs. The places where the dossier's reader was unsure were read in the source: the seventeen declarations of note 3, the statement of Proposition 5.2 with the place where it is applied, and the long proofs of Theorems 1, 4 and 5 and of Propositions 6.5, 7.3, 8.4, 9.2 and 9.3, whose automation was not replayed. Each inequality that the formal text leaves to automation was checked by hand, among them the constants 0.4, 1.6, $\frac{1}{20}$ and 5 of Theorem 1. The proofs follow the formal ones in substance. They differ in form in these places: Lemma 4.2 is proved term by term instead of by induction on the polynomial; the determinant in Proposition 5.2 is computed by an elimination instead of a factorisation and Sylvester's identity; Lemma 7.2(ii) is proved by expanding the product instead of by an adjointness for a pairing of polynomials; in Proposition 6.6 the determinant is seen not to vanish from the shape of the matrix instead of by a specialisation; Lemma 8.5 is proved directly; in Proposition 7.3 the form is a sum over the degrees instead of the result of an induction; and Theorem 3(b) averages over cyclic shifts instead of reflections. The diagram, the remarks after the definitions and the paragraph after Proposition 7.3 are mine. Lean was not run for this note.

An independent referee read the note against the Lean text. In the revision of 26 November 2026, after that report: the threshold and the parity received the letters $\mathfrak{t}$ and par (they were μ and ς); three steps were written out, namely the zero test in the proof of Lemma 7.1, the index of the parahoric subgroup in the proof of Theorem 3(a), and the units in the proof of Lemma 7.2; the references for the Inputs were sorted; and the notation list was completed. For the zero test and for the power of p in a binomial coefficient the formal proofs call lemmas of the library Mathlib (a homogeneous polynomial of degree at most the number of elements of an integral domain that vanishes at every point is zero; the exponent of p in $\binom{l'}{j}$ is at most the logarithm of l' to the base p). The proofs written here are mine and were not compared with the library's.

In these texts `ZMod N` is $\mathbb{Z}/L$, `Fin k` the set of the indices, `levi W τ` and `parahoric W τ` the two subgroups of the conventions, `⊥` the zero ideal, `weight c α` the sum $\langle\omega, \alpha\rangle$, and `volume.real` the volume as a real number; note 2 of §11 gives the letters.

Notation

L, s, s', s_0, s_1, $[s - s_0]$ the number of letters; letters, elements of $\mathbb{Z}/L$; the representative in $\{0, \dots, L-1\}$

k, i, i', l, l', l_1, i_0, i_1 the number of indices; indices $0, \dots, k-1$; a pair of indices (l, l' are also natural numbers)

v, x_v, $x_{i,s}$ a variable (i, s); the variables of the polynomial ring

W, $\mathfrak{m}_W$, $\mathbb{F}_W$ a local ring, its maximal ideal, its residue field

$\mathcal{O}$, $\mathcal{O}'$, $\mathfrak{m}$, $\mathbb{F}$, $\mathbb{F}'$ rings; the maximal ideal of a valuation domain; fields

T, p, o, ι_s, par_T, ϖ twisting data and their components (Definition 2.1)

$\mathrm{TD}_L(W, \mathcal{O})$, P_T, q_T, $\chi_* T$, $\bar{T}$ the set of twisting data; p^o; P_T^L; the image under a ring homomorphism; the reduction

γ, γ', γ_0, γ_1, γ_v, γ_ϵ, γ^{T} elements of $\mathrm{GL}_k(W)$; the transpose

$\gamma_{T,s}$, $[\gamma]_T$, $\rho_{T,n}(\gamma)$ the letter matrix, the action on polynomials, the matrix on forms (Definition 2.3)

τ, $\tau_{k,\mathfrak{t}}(\cdot)$, $\mathrm{Lev}_\tau(W)$, $\mathrm{Par}_\tau(W)$, Lev°, Par° labellings; Levi and parahoric subgroups

n, n', n_0, $\mathfrak{t}$, λ, j, j_0, e, e_0, e_i, c, m, m_y, r natural numbers: degrees, the threshold of the depth, $L/2$, levels and steps, exponents, counts, an index of summation

α, α', α'', α^*, $\alpha_s^\pm$, ν, $\hat{\nu}$, ν_s exponents; values at root variables; exponents on generic variables

β, β', β'', β_0, $\mathrm{Mon}_{k,n}$, $\mathrm{Mon}_{k,n}^L$ families; exponents of degree n; the set of families

F, F', F_1, F_2, F_ν, F°, $F^\flat$ forms and vectors of forms; the Hecke operator applied to F

Φ, Φ', Φ_0, Φ_v, Φ_υ, Φ^*, X polynomials; a further variable (also a matrix, in Input 2)

ω, ω_0, $\omega_s^\pm$, $\langle\omega, \alpha\rangle$ weights; the weighted sum

$\mathrm{dp}_{T,\mathfrak{t}}(v)$, $\mathrm{depth}_{T,\mathfrak{t}}^{k,n}(\beta)$ the indicator of deep variables; the depth

$\mathrm{rt}_{T,s}(i_0, i_1)$, $\mathrm{ex}_{T,s_0}^{i_0,i_1}(v)$ the root variable; the excess weight

$\mathrm{Tr}_{T,n}(\tau; I, \mathcal{B})$, $\mathrm{Ex}_{T,n}^{i_0,i_1}(I; h)$, $\mathrm{Dp}_{T,\mathfrak{t}}^{k,n}(j)$ the modules of forms of Definition 2.6; I an ideal, $\mathcal{B}$ a set of families, h a real number

$\mathcal{F}$, $\mathcal{G}$, $\mathcal{G}_\pm$, θ, θ', θ_0, $\mathrm{ad}_\varpi(\theta)$, $\mathrm{Gs}_{\mathcal{F},\omega}(\theta)$ families of subgroups; real levels; the filtrations of Definition 2.7

χ, χ', χ_0, χ_1, χ_υ, $\mathcal{A}$ ring homomorphisms; an algebra

υ, υ_0, $\upsilon_\mathfrak{s}$, π, π', π_0, π_1, π_2 elements of W and points; elements of $\mathcal{O}$

ϵ, ε_y, ε'_y a real number; diagonal entries of a Smith form

par, ϱ, σ, σ', τ', δ, δ', $\mathcal{C}$ a map from the letters to the signs (for twisting data, the parity par_T), a real number > 1, permutations, levels of a slab, a cone

$\mathrm{St}_{\mathrm{par},\varrho,\sigma}$, $\mathrm{Sl}_k(\delta)$, $\mathrm{Pc}_{\mathrm{par},\varrho}$, $\mathrm{Ec}_T(i_1; h)$ the step, the slab and the cones of Definition 2.8

ξ, η, η', $\xi^\downarrow$, σ°, $\sigma^\bullet$, vol real vectors; a rearrangement; two special vectors; Lebesgue measure

q, Q, P' ϱ^L or q_T; a power of q_T; a power of P_T

κ, y, z, κ_0, $\mathrm{Sz}(P,o,L,k,n,\mathfrak{t};\lambda,\kappa,y,z)$ real numbers; the size conditions (Definition 2.9); P stands for a natural number there

X_s, $x_{s,i,i'}$, $X_T^{\mathrm{Fr}}(s,j)$, $\mathrm{Fr}_{T,\mathfrak{t},\lambda,n}(\psi)$, ψ, Π_s^m, B_s generic matrices and the Frobenius operator (Definition 2.10)

$\mathrm{cj}_{T,\gamma,s}$, $\mathrm{iw}_{T,\lambda}^{i_0,i_1}(i)$, $\mathrm{cs}_\chi(\gamma)$, $G^{(j)}$ conjugation, index weights, the substitution by conjugation; entrywise powers

$E_{ii'}$ the matrix with the entry 1 at (i,i') and 0 elsewhere

G, G_s, S, S_α, N_s, A_s, U, U', U_1, U_2, Δ, J, J_1, J_2, H matrices

A, B, A', C, C_0, C_1, A_1, A_2, Z, w, w_0, w' the matrices of §9; the projector and the diagonal form

$\mathcal{M}$, $\mathcal{M}_j$, $\mathcal{M}_s^\pm$, $\mathcal{L}$, $\mathcal{L}'$, $\mathcal{L}_0$, $\mathcal{L}^\circ$, Ω linear forms on polynomials; a set of real numbers

V, V', V_j, V_j^Ω, M_0, M_1, M_2, M_3, M_1', M_2', Ψ, Y modules and submodules; a linear map; an endomorphism

$[M_1:M_2] \mid \pi$ the index of M_2 in M_1 divides π (Input 1)

$\mathcal{X}$, $\mathcal{X}'$, $\mathcal{E}$, $\mathcal{E}'$, $\mathcal{H}$, $\mathcal{I}$, $\mathcal{Q}$, $\mathcal{N}$, $\mathcal{K}$, $\mathcal{S}$, $\mathcal{V}$, $\mathcal{R}$, $\mathcal{Y}$, $\mathcal{Y}_0$, $\mathcal{U}$, $\mathcal{W}$, $\mathcal{J}$, Γ, Υ, Ξ finite sets, sets of indices and of points, a ring ($\mathcal{R}$), a module (Ξ)

$\mathfrak{x}$, $\mathfrak{q}$, $\tilde{\mathfrak{q}}$, $\mathfrak{e}$, $\mathfrak{e}'$, $\mathfrak{h}$, $\mathfrak{i}$, $\mathfrak{s}$, y, y_1, y_2 elements of $\mathcal{X}$, $\mathcal{Q}$, $\mathcal{E}$, $\mathcal{H}$, $\mathcal{I}$, $\mathcal{S}$, $\mathcal{Y}$ (the letter y is also a real number)

$u_{\mathfrak{e}}$, $\jmath$, $\beta_{\mathfrak{i}}$, $\mathfrak{h}_{\mathfrak{i}}$, $\mathbf{u}$, $\mathbf{Z}$, $\mathbf{w}$, $\mathbf{l}$, $\mathbf{v}$, e_y the data of Theorem 5; operators in its proof; a sequence of indices; a vector; unit vectors

$\mathrm{w}^\pm(\alpha')$, $\mathrm{w}^\pm(\upsilon)$, sg_s, sg, t_υ in the proof of Theorem 1: two weighted degrees of an exponent and their coefficients, a sign (also in Proposition 8.4), the translation $X \mapsto X + \iota_{s_0}(\upsilon)$

$\mathrm{dt}(\sigma')$, σ'^*, S_σ, Sh, N, El in Proposition 5.2: $|\det(1-\varrho^{-L}\sigma'^*)|$, a permutation acting on vectors, the step, the shift, the cyclic operator, the elimination

f_l, df_s, g_i the numbers $(q^{l+1}-1)/(q-1)$; differences of coordinates (Lemma 6.2); the numbers of Lemma 6.3

$\mathrm{cost}(\beta)$, $\varkappa$ the sum of Proposition 6.6; the map of Input 3 that gives the costs

$\mathrm{rw}(\alpha)$, $\mathrm{cw}(\alpha)$, $X^\intercal$, $e_{\mathbf{l}}$, $|\mathbf{l}|_\omega$, $\mathrm{K}(\Phi)$ in Proposition 7.3: the row and column weights of an exponent on the generic variables, the generic matrix of a Levi subgroup, a basis vector and its weight, the vector $(w(\alpha)\Phi_\alpha)_\alpha$

$\mathrm{a}_m(i)$, $\eta_{s,j}(i)$, Fr, $Z(\mathcal{L})$, cf_ν, $\mathrm{bil}(\mathcal{L})$ in §8: real numbers, the generic Frobenius operator, its image under a product of forms, a coefficient, the bilinear expression of property (ii)

res, src, pt, pt_1, pt_2, r the residue map; maps to $\mathcal{X}$ (Theorem 5, Proposition 9.3); an isomorphism in the proof of Theorem 5

$\mathrm{d}(\beta)$, $\mathrm{ord}(\beta')$ in §9: the depth $\mathrm{depth}_{T,i_1}^{k,n}(\beta)$; the order of divisibility defined in the proof of Proposition 9.3

μ, ς; k', a', q', r', c_1, c_2, c_3, ϕ_s letters of the write-up that this note does not use (after Setting 2.2); letters of the note on unit 145 (after Theorem 5)

N, r, ℓ, a, b, d, f, g, x, D, K, O, R, M letters of the formal text, used only in §11 and after Definition 2.9; $a(D)$ is a number of the handout (§10)

READBACK NOTE 15

A crude bound for a class number, and divisibility of indices of submodules

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The unit holds two pieces of bookkeeping that do not depend on each other. The first is an explicit, crude bound for the number of classes in the genus of the standard lattice of a definite hermitian space over a CM field: each class is recorded by two matrices of algebraic integers of bounded size, and such matrices are counted. The second is a way to say, over an arbitrary commutative ring, that the index of one submodule in another divides a given element: every finite family of the first is moved into the second by a square matrix whose determinant divides that element. The unit proves the calculus of this notion and a criterion by determinants over a valuation domain, which rests on the Hermite normal form. Both pieces serve Theorem A of the write-up (short forms), and the first also Theorem C: the class number enters the sizes of the columns and, through two bounds of the unit of the columns, the units of the rows and of the exchange; the index language is the one in which the losses of divisibility at single primes are stated.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, of the Riemann hypothesis and of its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles with Lean v4.35.0 against a pinned version of the library Mathlib and that Lean's kernel accepted the proofs; an independent build is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note treats one unit of the artifact: all 11 of its 11 declarations. Their proofs are given in full, *given* four results of other units, which are stated as Inputs 1 to 4 and not proved here: two lemmas of reduction theory, a count of bounded integral vectors, and the Hermite normal form (its second part, Input 4(b), is stated with its proof of two lines). Every statement of the unit and of the Inputs was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 20 declarations.

1 The statements

The notions are defined in §2. In short: for a CM field E and a finite set $\mathcal{J}$, $\mathrm{Cl}(\mathrm{U}_{\mathcal{J}}(\widehat{\mathcal{O}}_E))$ is the set of classes in the genus of the standard lattice of the hermitian space $E^{\mathcal{J}}$ with the form $\sum_i \bar{v}_i v_i$; $f(E)$ is the number of infinite places of E; and $c_{\mathrm{sb}}(E,\mathcal{J},N') = 6N'(f(E)\cdot\#\mathcal{J})^2$. For submodules A, B of a module and a ring element z, $[A:B] \mid z$ is read *the index of B in A divides z*; it is one symbol, defined in Definition 2.1.

Theorem 1 (a crude bound for the class number). *Let E be a CM field with a CM type, let $N' \geq 1$ be an integer whose image in the ring of integers of E lies in the different of E, and let $\mathcal{J}$ be a finite set. Then*

$$\#\,\mathrm{Cl}(\mathrm{U}_{\mathcal{J}}(\widehat{\mathcal{O}}_E)) \;\leq\; \left(1 + 2\,c_{\mathrm{sb}}(E, \mathcal{J}, N')^3\right)^{4\,f(E)\,(\#\mathcal{J})^2}.$$

Theorem 2 (the determinant criterion). *Let $\mathcal{O}$ be a valuation domain, $\mathcal{J}$ a finite set, z an element of $\mathcal{O}$, and G a square matrix over $\mathcal{O}$ with rows and columns indexed by $\mathcal{J}$; in words, a matrix G in $\mathrm{M}_{\mathcal{J}}(\mathcal{O})$. Let B be a submodule of $\mathcal{O}^{\mathcal{J}}$. If $\det G$ divides z and $G(\mathcal{O}^{\mathcal{J}}) \subseteq B$, then $[\mathcal{O}^{\mathcal{J}} : B] \mid z$.*

LEAN `Space.card_classes_le` · `IndexDvd.of_det_dvd`

In Theorem 1 the number of elements is taken as the formal text takes it, a natural number that would be 0 for an infinite set; the proof shows that the set is finite (§7, note 1). Between the two theorems stands the calculus of §4: inclusion, pull-back, transitivity, push-forward, sums and composition (Lemmas 4.1 to 4.6), and the additivity of the *type* of an endomorphism under composition (Proposition 4.7).

2 The setting

Conventions. The natural numbers are $0, 1, 2, \ldots$. Every ring is a commutative ring with 1. In §4 and §5, $\mathcal{O}$ is a commutative ring, V and V' are $\mathcal{O}$-modules, and a submodule is an $\mathcal{O}$-submodule of a module. For submodules A, B of one module, $A + B$ is their sum; for an element w of $\mathcal{O}$, wA is the submodule of the multiples wv, $v \in A$; for a linear map G, $G(A)$ is the image and $G^{-1}(B)$ the preimage of a submodule. A *valuation domain* is an integral domain in which, of any two elements, one divides the other. A finite set indexes coordinates: for a finite set $\mathcal{J}$, $\mathcal{O}^{\mathcal{J}}$ is the module of families $(v_i)_{i \in \mathcal{J}}$, $\mathrm{M}_{\mathcal{J}}(\mathcal{O})$ is the ring of matrices with rows and columns indexed by $\mathcal{J}$, acting on $\mathcal{O}^{\mathcal{J}}$, and $\mathrm{GL}_{\mathcal{J}}(\mathcal{O})$ is its group of units. The number of elements of a finite set $\mathcal{S}$ is $\#\mathcal{S}$.

In §3, E is a CM field: a totally complex quadratic extension of a totally real number field. Complex conjugation of E is written $v \mapsto \bar{v}$. A *CM type* of E is a family $(\iota_\tau)_\tau$ of field embeddings $\iota_\tau \colon E \to \mathbb{C}$, one for each infinite place τ of E, such that ι_τ induces τ. The ring of integers of E is $\mathcal{O}_E$, its different (over $\mathbb{Z}$) is the ideal whose inverse is the dual of $\mathcal{O}_E$ for the trace form. The ring of finite adeles of E is $\mathbb{A}_{E,f}$, and $\widehat{\mathcal{O}}_E$ is the closure of $\mathcal{O}_E$ in it, the product of the rings of integers of the completions of E at the finite places; E is a subring of $\mathbb{A}_{E,f}$, and $E \cap \widehat{\mathcal{O}}_E = \mathcal{O}_E$. Complex conjugation extends to $\mathbb{A}_{E,f}$ and preserves $\widehat{\mathcal{O}}_E$. For a matrix h over E or over $\mathbb{A}_{E,f}$, h^* is its conjugate transpose.

Letters. Three letters differ from those of the formal text, because the write-up keeps M, K and Φ for a modulus, for the imaginary quadratic field and for a function of Chapter I: the integer in the different of E is N', as in the note on the unit of the columns (unit 145), a level is K, and the embeddings of the CM type are ι_τ, for the infinite places τ, as in the overview.

Definition 2.1 (index divisibility)**.** Let A and B be submodules of the $\mathcal{O}$-module V, and let z be an element of $\mathcal{O}$. We write

$$[A : B] \mid z$$

and say that *the index of B in A divides z*, if for every natural number n and all elements $y_1, \dots, y_n$ of A there is an $n \times n$ matrix $u = (u_{ii'})$ over $\mathcal{O}$ such that $\det u$ divides z and

$$\sum_{i'=1}^{n} u_{ii'}\, y_{i'} \in B \qquad \text{for } i = 1, \dots, n.$$

LEAN `IndexDvd`

The definition does not ask that B lie in A, nor that either module be free or finitely generated. Since the combinations $\sum_{i'} u_{ii'} y_{i'}$ lie in A, the statement $[A : B] \mid z$ depends on B only through $A \cap B$; it holds for $z = 0$ (take $u = 0$), and for every z when $A \subseteq B$ (Lemma 4.1). The bracket alone has no meaning. Remark 5.1 compares the notion with the length of a quotient in the one case where both are defined. The overview of the handout uses the same pattern for the index of a family of rows: there, too, a square matrix u moves a family into the integral forms, and what is bounded is the divisibility of its determinant: at each prime the absolute value of $\det u$ is bounded from below, as here $\det u$ divides z.

Definition 2.2 (type of an endomorphism)**.** Let p be an element of $\mathcal{O}$, A a submodule of the $\mathcal{O}$-module V, ν a natural number, Y an $\mathcal{O}$-linear endomorphism of V, and c a real number. We say that

$$Y \text{ has type at most } c \text{ at } p^{\nu} \text{ on } A$$

if $Y(A) \subseteq A$ and there is a natural number $i \le c$ with $[A : Y(A) + p^{\nu} A] \mid p^{i}$.

LEAN `HasType`

When $\mathcal{O}$ is a discrete valuation ring with uniformiser p and A is free of finite rank, this says that Y preserves A and that the cokernel of Y on $A/p^{\nu}A$ has length at most c (Remark 5.1): the elementary divisors of Y on A, cut off at p^{ν}, have exponents of sum at most c.

Definition 2.3 (the standard definite space and its classes)**.** Let E be a CM field and $\mathcal{J}$ a finite set.

(a) $\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$ is the group of the matrices h in $\mathrm{GL}_{\mathcal{J}}(\mathbb{A}_{E,f})$ with $h^{*}h = 1$: the finite adelic points of the unitary group of the hermitian form $\sum_{i \in \mathcal{J}} \bar{v}_i v_i$ on $E^{\mathcal{J}}$. $\mathrm{U}_{\mathcal{J}}(E)$ is the group of the matrices γ in $\mathrm{GL}_{\mathcal{J}}(E)$ with $\gamma^{*}\gamma = 1$; it is a subgroup of $\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$. The subgroup

$$\mathrm{U}_{\mathcal{J}}(\widehat{\mathcal{O}}_E)$$

of $\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$ consists of the elements h such that h and h^{-1} have all entries in $\widehat{\mathcal{O}}_E$; it is the stabiliser of the standard lattice $\widehat{\mathcal{O}}_E^{\mathcal{J}}$.

(b) For a subgroup K of $\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$, the set of *classes at level* K is the set of double cosets

$$\mathrm{Cl}(\mathsf{K}) = \mathrm{U}_{\mathcal{J}}(E) \backslash \mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f}) / \mathsf{K}.$$

(c) $f(E)$ is the number of infinite places of E; this is defined for every number field.

(d) For a natural number N', $c_{\mathrm{sb}}(E, \mathcal{J}, N') = 6\, N' \, (f(E) \cdot \#\mathcal{J})^{2}$, a natural number.

LEAN `Kf` · `StdClasses` · `numInfPlaces` · `Space.shortBasisConst` · these four definitions belong to the background library (units 122, 102, 10 and 99)

The classes at level $\mathrm{U}_{\mathcal{J}}(\widehat{\mathcal{O}}_E)$ correspond to the isometry classes of the hermitian lattices in $E^{\mathcal{J}}$ that are everywhere locally isometric to $\mathcal{O}_E^{\mathcal{J}}$: the class of h is that of the lattice $E^{\mathcal{J}} \cap h\,\widehat{\mathcal{O}}_E^{\mathcal{J}}$. The number of classes is the class number of the genus.

Inputs from other units. The four results below are taken for granted in this note; only Input 4(b) is proved, in its place.

Input 1 (short bases; unit 99, background). *Let E be a CM field with a CM type, $\mathcal{J}$ a finite set, and $N' \geq 1$ an integer that, as an element of $\mathcal{O}_E$, lies in the different of E. For every h in $\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$ there is a matrix L in $\mathrm{GL}_{\mathcal{J}}(E)$ such that $h^{-1}L$ has all entries in $\widehat{\mathcal{O}}_E$ and $|\varphi(L_{ii'})| \leq c_{\mathrm{sb}}(E, \mathcal{J}, N')$ for every ring homomorphism $\varphi\colon E \to \mathbb{C}$ and all i, i' in $\mathcal{J}$.*

Input 2 (rational approximation of an adele; unit 99, background). *Let E be a CM field with a CM type $(\iota_\tau)_\tau$, and let δ be a nonzero element of the different of E. For every family $(z_\tau)_\tau$ of complex numbers indexed by the infinite places of E and every finite adele η in $\mathbb{A}_{E,f}$ there is α in E with $\eta - \alpha \in \widehat{\mathcal{O}}_E$ and $|z_\tau - \iota_\tau(\alpha)| \leq (2\,f(E))^2\,|\iota_\tau(\delta)|$ for every infinite place τ.*

Input 3 (bounded integral vectors are few; unit 148). *Let E' be a number field with an embedding $\iota_\tau\colon E' \to \mathbb{C}$ inducing τ for each infinite place τ of E'. Let $\mathcal{S}$ be a set, $\mathcal{S}'$ a subset of it, $\mathcal{J}$ a finite set, ω a real number with $0 \leq \omega$, and F a map from $\mathcal{S}$ to $E'^{\mathcal{J}}$. Suppose that for every c in $\mathcal{S}'$ and every i in $\mathcal{J}$ the coordinate $F(c)_i$ is an algebraic integer with $|\iota_\tau(F(c)_i)| \leq \omega$ for every τ, and that F is injective on $\mathcal{S}'$. Then $\mathcal{S}'$ is finite, with at most $(1+2\omega)^{2\,\#\mathcal{J}\,f(E')}$ elements.* (The reading of this lemma by program lists, besides these arguments, variables of its file that the statement does not mention, among them a matrix; by Lean's rules for such variables they are not arguments of the lemma.)

Input 4 (Hermite normal form; unit 120, background). (a) *Let $\mathcal{A}$ be a commutative ring and $\mathcal{R}$ a subring such that $(\mathcal{A}, \mathcal{R})$ is a valuation pair: for any two elements y, y' of $\mathcal{A}$ there is an idempotent ϵ of $\mathcal{R}$ with $\mathcal{R}y + \mathcal{R}y' \subseteq \mathcal{R}\,(y - \epsilon(y - y'))$. Let $\mathcal{K}$ and $\mathcal{N}$ be finite sets, $\jmath\colon \mathcal{K} \to \mathcal{N}$ an injective map, X a matrix over $\mathcal{A}$ with rows indexed by $\mathcal{N}$ and columns by $\mathcal{K}$, and ω a map from $\mathcal{K}$ to the natural numbers (weights). Then there are an invertible matrix T over $\mathcal{A}$, indexed by $\mathcal{N}$, such that T and T^{-1} have their entries in $\mathcal{R}$, and a square matrix Δ over $\mathcal{A}$, indexed by $\mathcal{K}$, with $\Delta_{ll'} = 0$ whenever $\omega(l') < \omega(l)$, such that*

$$X = T_{\cdot,\jmath}\,\Delta \qquad \text{and} \qquad (T^{-1})_{\jmath,\cdot}\,X = \Delta,$$

where $T_{\cdot,\jmath}$ consists of the columns $\jmath(l)$ of T and $(T^{-1})_{\jmath,\cdot}$ of the rows $\jmath(l)$ of T^{-1}, $l \in \mathcal{K}$. (b) *If $\mathcal{A}$ is a valuation domain, then $(\mathcal{A}, \mathcal{A})$ is a valuation pair.* (Proof of (b): take $\epsilon = 0$ if y divides y', so that $\mathcal{A}y + \mathcal{A}y' = \mathcal{A}y$; otherwise y' divides y, and $\epsilon = 1$ gives $y - (y - y') = y'$ and $\mathcal{A}y + \mathcal{A}y' = \mathcal{A}y'$. The reading of (a) by program also lists a ring with involution, from an earlier part of its file; the statement does not involve it.)

LEAN `Space.exists_short_basis_stdSpace` · `exists_rat_near_of_mem_differentIdeal` · `Filling.encard_integral_le` · `IsValuationPair.hermite` · `isValuationPair_top`

Inputs 1 and 2 are lemmas of the reduction theory that the artifact develops for the standard space: Input 1 comes from a transference argument (a basis of short vectors, from the covering radius of a lattice against the first minimum of its dual), Input 2 from a fundamental domain for $\mathcal{O}_E$ scaled by the different. Input 3 is a packing count: distinct algebraic integers are at distance at least 1 at some infinite place. Input 4(a), for a discrete valuation ring and $\mathcal{K} = \mathcal{N}$, is the Hermite form obtained by row operations: $\Delta = T^{-1}X$ is X multiplied on the left by an invertible matrix with entries in $\mathcal{R}$, and Δ is block triangular for the weights ω. The valuation pair is the form in which the artifact proves it once for a valuation domain and for $\widehat{\mathcal{O}}_E$ inside $\mathbb{A}_{E,f}$.

References. The catalogue of quoted results of this write-up lists Inputs 1, 2 and 4(a) as elementary lemmas, with no confirmed place in the literature. For Input 1 it names the theorem behind it, the general short-basis lemma of the same file of the artifact, as a known result, the transference theorem, with the references W. Banaszczyk, *New bounds in some transference theorems in the geometry of numbers*, Math. Ann. 296 (1993), Theorems (2.1) and (2.2), and J. C. Lagarias, H. W. Lenstra Jr. and C. P. Schnorr, *Korkin–Zolotarev bases and successive minima of a lattice and its reciprocal lattice*, Combinatorica 10 (1990), Theorems 2.4–2.5. The relation recorded there is that of a weaker form: those theorems, with a computation of the dual lattice for the trace form, give a smaller radius than the artifact's lemma; Input 1 is the case of the standard space of that lemma. For Input 2: *reference to be confirmed.* Input 3 is a result of the argument (unit 148), not of the literature. Input 4(a) is used in this note only for a valuation domain and the pair $(\mathcal{A}, \mathcal{A})$; there the reduction of a matrix to triangular form by an invertible matrix is classical. A source for rings with such reductions is I. Kaplansky, *Elementary divisors and modules*, Trans. Amer. Math. Soc. 66 (1949), 464–491; the place in it was not confirmed, and for the form with a valuation pair no place is known to us: *reference to be confirmed.*

3 The class number

Proof of Theorem 1. Write Cl for the set $\mathrm{Cl}(\mathrm{U}_{\mathcal{J}}(\widehat{\mathcal{O}}_E))$, and choose for every class $\mathfrak{c}$ in it a representative $h_{\mathfrak{c}}$ in $\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$.

Short bases. By Input 1 there is, for every class $\mathfrak{c}$, a matrix $L_{\mathfrak{c}}$ in $\mathrm{GL}_{\mathcal{J}}(E)$ such that

$$Q_{\mathfrak{c}} = h_{\mathfrak{c}}^{-1} L_{\mathfrak{c}} \quad \text{has its entries in } \widehat{\mathcal{O}}_E$$

and

$$|\varphi((L_{\mathfrak{c}})_{ii'})| \le c_{\mathrm{sb}}(E, \mathcal{J}, N') \quad \text{for every ring homomorphism } \varphi\colon E \to \mathbb{C} \text{ and all } i, i'.$$

Let $H_{\mathfrak{c}} = L_{\mathfrak{c}}^{*} L_{\mathfrak{c}}$, the Gram matrix of the columns of $L_{\mathfrak{c}}$; it lies in $\mathrm{GL}_{\mathcal{J}}(E)$.

An approximate inverse. Apply Input 2 with $\delta = N'$ and $z_\tau = 0$: for every finite adele η there is $\varrho(\eta)$ in E with

$$\eta - \varrho(\eta) \in \widehat{\mathcal{O}}_E, \qquad |\iota_\tau(\varrho(\eta))| \le (2\, f(E))^2 N' \quad \text{for every infinite place } \tau.$$

Let $Z_{\mathfrak{c}}$ be the matrix over E obtained by applying ϱ to each entry of $Q_{\mathfrak{c}}^{-1}$. Then $Q_{\mathfrak{c}}^{-1} - Z_{\mathfrak{c}}$ has its entries in $\widehat{\mathcal{O}}_E$, and so, for all classes $\mathfrak{c}$ and $\mathfrak{c}'$,

$$Q_{\mathfrak{c}'} Q_{\mathfrak{c}}^{-1} - Q_{\mathfrak{c}'} Z_{\mathfrak{c}} = Q_{\mathfrak{c}'}(Q_{\mathfrak{c}}^{-1} - Z_{\mathfrak{c}}) \quad \text{has its entries in } \widehat{\mathcal{O}}_E. \tag{1}$$

The map. Send a class $\mathfrak{c}$ to the pair of matrices $(H_{\mathfrak{c}},\, H_{\mathfrak{c}}Z_{\mathfrak{c}})$, a vector with $2(\#\mathcal{J})^2$ coordinates in E. We show that its coordinates are algebraic integers, that they are bounded by $c_{\mathrm{sb}}(E,\mathcal{J},N')^3$ at every infinite place, and that the map is injective. Input 3, for the field E with its CM type, the set $\mathcal{S}=\mathcal{S}'=\mathrm{Cl}$, an index set of $2(\#\mathcal{J})^2$ elements and $\omega=c_{\mathrm{sb}}(E,\mathcal{J},N')^3$, then shows that Cl is finite with at most $(1+2\,c_{\mathrm{sb}}(E,\mathcal{J},N')^3)^{2\cdot 2(\#\mathcal{J})^2\cdot f(E)}$ elements, which is the bound of the theorem.

Integrality. Since $h_{\mathfrak{c}}^{-1}$ is unitary, $H_{\mathfrak{c}}=(h_{\mathfrak{c}}^{-1}L_{\mathfrak{c}})^*(h_{\mathfrak{c}}^{-1}L_{\mathfrak{c}})=Q_{\mathfrak{c}}^*Q_{\mathfrak{c}}$, and the entries of $Q_{\mathfrak{c}}^*$ lie in $\widehat{\mathcal{O}}_E$ because conjugation preserves $\widehat{\mathcal{O}}_E$. So $H_{\mathfrak{c}}$ has its entries in $E\cap\widehat{\mathcal{O}}_E=\mathcal{O}_E$. In the same way $H_{\mathfrak{c}}Z_{\mathfrak{c}}=Q_{\mathfrak{c}}^*\,(Q_{\mathfrak{c}}Z_{\mathfrak{c}})$, and $Q_{\mathfrak{c}}Z_{\mathfrak{c}}=1-Q_{\mathfrak{c}}(Q_{\mathfrak{c}}^{-1}-Z_{\mathfrak{c}})$ has its entries in $\widehat{\mathcal{O}}_E$ by (1) with $\mathfrak{c}'=\mathfrak{c}$.

Size. Let τ be an infinite place. The composite of ι_τ with complex conjugation of E is again a ring homomorphism from E to $\mathbb{C}$, so every entry of $L_{\mathfrak{c}}$ and of $L_{\mathfrak{c}}^*$ has absolute value at most $c_{\mathrm{sb}}(E,\mathcal{J},N')$ under ι_τ. Hence

$$|\iota_\tau((H_{\mathfrak{c}})_{ii'})|\le \#\mathcal{J}\cdot c_{\mathrm{sb}}(E,\mathcal{J},N')^2,$$
$$|\iota_\tau((H_{\mathfrak{c}}Z_{\mathfrak{c}})_{ii'})|\le (\#\mathcal{J})^2\,c_{\mathrm{sb}}(E,\mathcal{J},N')^2\,(2\,f(E))^2N'.$$

Here $\#\mathcal{J}\ge 1$, as there is an entry, and $N'\ge 1$, $f(E)\ge 1$. So

$$\#\mathcal{J}\le c_{\mathrm{sb}}(E,\mathcal{J},N')\qquad\text{and}\qquad 4N'\,f(E)^2(\#\mathcal{J})^2\le 6N'(f(E)\cdot\#\mathcal{J})^2=c_{\mathrm{sb}}(E,\mathcal{J},N'),$$

and both bounds are at most the cube of $c_{\mathrm{sb}}(E,\mathcal{J},N')$.

Injectivity. Let $\mathfrak{c}$ and $\mathfrak{c}'$ be classes with $H_{\mathfrak{c}}=H_{\mathfrak{c}'}$ and $H_{\mathfrak{c}}Z_{\mathfrak{c}}=H_{\mathfrak{c}'}Z_{\mathfrak{c}'}$. As $H_{\mathfrak{c}}$ is invertible, $Z_{\mathfrak{c}}=Z_{\mathfrak{c}'}$. Put $\gamma=L_{\mathfrak{c}}L_{\mathfrak{c}'}^{-1}$, a matrix in $\mathrm{GL}_{\mathcal{J}}(E)$. Then

$$\gamma^*\gamma=(L_{\mathfrak{c}'}^{-1})^*\,H_{\mathfrak{c}}\,L_{\mathfrak{c}'}^{-1}=(L_{\mathfrak{c}'}^{-1})^*\,H_{\mathfrak{c}'}\,L_{\mathfrak{c}'}^{-1}=1,$$

so γ lies in $\mathrm{U}_{\mathcal{J}}(E)$. Put $\kappa=(\gamma h_{\mathfrak{c}'})^{-1}h_{\mathfrak{c}}$, an element of $\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$. Then

$$\kappa=h_{\mathfrak{c}'}^{-1}L_{\mathfrak{c}'}L_{\mathfrak{c}}^{-1}h_{\mathfrak{c}}=Q_{\mathfrak{c}'}Q_{\mathfrak{c}}^{-1},$$

and by (1), used for the pairs $(\mathfrak{c},\mathfrak{c}')$ and $(\mathfrak{c}',\mathfrak{c}')$, and by $Z_{\mathfrak{c}}=Z_{\mathfrak{c}'}$,

$$\kappa=1+(Q_{\mathfrak{c}'}Q_{\mathfrak{c}}^{-1}-Q_{\mathfrak{c}'}Z_{\mathfrak{c}})-(Q_{\mathfrak{c}'}Q_{\mathfrak{c}'}^{-1}-Q_{\mathfrak{c}'}Z_{\mathfrak{c}'})$$

has its entries in $\widehat{\mathcal{O}}_E$. The inverse of the unitary matrix κ is κ^*, which has its entries in $\widehat{\mathcal{O}}_E$ as well, so κ lies in $\mathrm{U}_{\mathcal{J}}(\widehat{\mathcal{O}}_E)$. From $h_{\mathfrak{c}}=\gamma\,h_{\mathfrak{c}'}\,\kappa$ the two representatives lie in one double coset, and $\mathfrak{c}=\mathfrak{c}'$. □

LEAN `Space.card_classes_le` · the formal proof has these five parts in this order

The bound is crude. (The mass formula of Smith, Minkowski and Siegel gives the sum of the inverses of the orders of the automorphism groups over the classes, hence a lower bound for their number; we make no comparison.) What the argument of the write-up needs is a bound that is explicit and at most exponential in a polynomial of $f(E)$, $\#\mathcal{J}$ and N'.

4 The calculus of index divisibility

In this section $\mathcal{O}$ is a commutative ring and V, V' are $\mathcal{O}$-modules, as in the conventions.

Lemma 4.1 (inclusion)**.** *Let A and B be submodules of V and z an element of $\mathcal{O}$. If $A \subseteq B$, then $[A : B] \mid z$.*

Proof. For $y_1, \dots, y_n$ in A the identity matrix serves: its determinant 1 divides z, and each y_i lies in B. □

LEAN `IndexDvd.of_le`

Lemma 4.2 (pull-back)**.** *Let A, B be submodules of V, let A', B' be submodules of V', let z be an element of $\mathcal{O}$, and let $G : V' \to V$ be an $\mathcal{O}$-linear map. Suppose that $[A : B] \mid z$, that $G(A') \subseteq A$, and that every v in A' with $G(v) \in B$ lies in B'. Then $[A' : B'] \mid z$.*

Proof. Let $y_1, \dots, y_n$ lie in A'. The elements $G(y_i)$ lie in A, so there is a matrix u with $\det u$ dividing z and $\sum_{i'} u_{ii'} G(y_{i'}) \in B$ for all i. The element $v_i = \sum_{i'} u_{ii'} y_{i'}$ lies in A' and $G(v_i) \in B$; hence $v_i \in B'$. □

LEAN `IndexDvd.comap`

Lemma 4.3 (transitivity)**.** *Let A, B, C be submodules of V and let z and w be elements of $\mathcal{O}$. If $[A : B] \mid z$ and $[B : C] \mid w$, then $[A : C] \mid zw$.*

Proof. Let $y_1, \dots, y_n$ lie in A. There is u with $\det u$ dividing z such that the elements $y'_i = \sum_{i'} u_{ii'} y_{i'}$ lie in B; and for these there is u' with $\det u'$ dividing w such that $\sum_i u'_{li} y'_i \in C$ for all l. The matrix $u'u$ has determinant $\det u' \cdot \det u$, which divides zw, and $\sum_{i'} (u'u)_{li'} y_{i'} = \sum_i u'_{li} y'_i$ lies in C. □

LEAN `IndexDvd.trans`

Lemma 4.4 (push-forward)**.** *Let A, B be submodules of V, let A', B' be submodules of V', let z be an element of $\mathcal{O}$, and let $G : V \to V'$ be an $\mathcal{O}$-linear map. Suppose that $[A : B] \mid z$, that $A' \subseteq G(A) + B'$, and that $G(B) \subseteq B'$. Then $[A' : B'] \mid z$.*

Proof. Let $y_1, \dots, y_n$ lie in A', and write $y_i = G(v_i) + b_i$ with v_i in A and b_i in B'. There is u with $\det u$ dividing z and $\sum_{i'} u_{ii'} v_{i'} \in B$ for all i. Then

$$\sum_{i'} u_{ii'} y_{i'} = G\Big(\sum_{i'} u_{ii'} v_{i'}\Big) + \sum_{i'} u_{ii'} b_{i'} \;\in\; G(B) + B' \subseteq B'. \qquad \square$$

LEAN `IndexDvd.map`

Lemma 4.5 (finite sums)**.** *Let $\mathcal{J}$ be a set, let $G_i : V \to V'$, for i in $\mathcal{J}$, be $\mathcal{O}$-linear maps, let A be a submodule of V, B' a submodule of V' and z an element of $\mathcal{O}$. Suppose that $[A : G_i^{-1}(B')] \mid z$ for every i in $\mathcal{J}$. Then for every finite subset $\mathcal{S}$ of $\mathcal{J}$,*

$$\Big[\textstyle\sum_{i \in \mathcal{S}} G_i(A) + B' : B'\Big] \mid z^{\#\mathcal{S}}.$$

Proof. By induction on $\mathcal{S}$. For the empty set the left module is B', and Lemma 4.1 applies. Let $\mathcal{S} = \mathcal{S}_0 \cup \{i\}$ with i not in $\mathcal{S}_0$, and put $A'_0 = \sum_{l \in \mathcal{S}_0} G_l(A) + B'$ and $A' = G_i(A) + A'_0$. Lemma 4.4, for the map G_i and the submodules A, $G_i^{-1}(B')$ of V and A', A'_0 of V', gives $[A' : A'_0] \mid z$: indeed $A' \subseteq G_i(A) + A'_0$ and $G_i(G_i^{-1}(B')) \subseteq B' \subseteq A'_0$. By the induction hypothesis $[A'_0 : B'] \mid z^{\#\mathcal{S}_0}$, and Lemma 4.3 gives the claim with $z \cdot z^{\#\mathcal{S}_0} = z^{\#\mathcal{S}}$. □

LEAN `IndexDvd.sup` · the formal statement writes the left module as the span of the union of the images $G_i(A)$, $i \in \mathcal{S}$, and of B'

Lemma 4.6 (composition)**.** *Let A and B be submodules of V, let z, z' and w be elements of $\mathcal{O}$, and let $G\colon V \to V$ be an $\mathcal{O}$-linear map with $G(A) \subseteq A$. If $[A : G(A) + wA] \mid z$ and $[A : B + wA] \mid z'$, then $[A : G(B) + wA] \mid zz'$.*

Proof. Apply Lemma 4.4 to the second hypothesis and the map G, with the submodules $A' = G(A) + wA$ and $B' = G(B) + wA$. The inclusion $A' \subseteq G(A) + B'$ is clear, and

$$G(B + wA) = G(B) + w\,G(A) \subseteq G(B) + wA$$

because $G(A) \subseteq A$. This gives $[G(A) + wA : G(B) + wA] \mid z'$. Lemma 4.3, with the first hypothesis, gives the claim. □

LEAN `IndexDvd.comp`

Proposition 4.7 (types add under composition)**.** *Let $\mathcal{J}$ be a set, and for every i in $\mathcal{J}$ let Y_i be an $\mathcal{O}$-linear endomorphism of V and c_i a real number. Let p be an element of $\mathcal{O}$ (the formal text calls it z), A a submodule of V and ν a natural number. Let $(i_1, \dots, i_e)$ be a finite list of elements of $\mathcal{J}$, with $e \geq 0$; repetitions are allowed. Suppose that Y_{i_l} has type at most c_{i_l} at p^ν on A for $l = 1, \dots, e$. Then $Y_{i_1} \circ \dots \circ Y_{i_e}$ has type at most $c_{i_1} + \cdots + c_{i_e}$ at p^ν on A; for $e = 0$ the composite is the identity and the sum is 0.*

Proof. By induction on e. For $e = 0$: the identity preserves A, and $[A : A + p^\nu A] \mid p^0$ by Lemma 4.1, with the natural number $0 \leq 0$. For the step put $Y = Y_{i_1}$ and $Y' = Y_{i_2} \circ \dots \circ Y_{i_e}$. By the hypothesis on Y there is a natural number $i \leq c_{i_1}$ with $[A : Y(A) + p^\nu A] \mid p^i$, and $Y(A) \subseteq A$; by the induction hypothesis $Y'(A) \subseteq A$ and there is a natural number $i' \leq c_{i_2} + \cdots + c_{i_e}$ with $[A : Y'(A) + p^\nu A] \mid p^{i'}$. Then $Y(Y'(A)) \subseteq Y(A) \subseteq A$, and Lemma 4.6, with $G = Y$, $B = Y'(A)$ and $w = p^\nu$, gives $[A : Y(Y'(A)) + p^\nu A] \mid p^{i+i'}$, where $i + i' \leq c_{i_1} + \cdots + c_{i_e}$. □

LEAN `HasType.prod`

5 The determinant criterion

Proof of Theorem 2. Let $y_1, \dots, y_n$ be elements of $\mathcal{O}^{\mathcal{J}}$; write $(y_i)_l$ for the coordinates, $l \in \mathcal{J}$, and let $\mathbf{y} = ((y_i)_l)_{i,l}$ be the matrix with rows indexed by $\{1, \dots, n\}$ and columns by $\mathcal{J}$. Let $\mathcal{N}$ be the disjoint union of $\{1, \dots, n\}$ and $\mathcal{J}$, and let X be the square matrix over $\mathcal{O}$, indexed by $\mathcal{N}$, with the blocks

$$X = \begin{pmatrix} 1 & -\mathbf{y} \\ 0 & G^{\mathsf{T}} \end{pmatrix},$$

where 1 is the identity matrix of size n and G^{T} is the transpose of G. By Input 4(b) the pair $(\mathcal{O}, \mathcal{O})$ is a valuation pair. Input 4(a), for $\mathcal{K} = \mathcal{N}$, the identity map $\jmath$, the matrix X and the weights $\omega = 1$ on $\{1, \dots, n\}$ and $\omega = 0$ on $\mathcal{J}$, gives an invertible matrix T over $\mathcal{O}$ whose inverse has entries in $\mathcal{O}$, and a matrix Δ with

$$X = T\Delta, \qquad T^{-1}X = \Delta, \qquad \Delta_{il} = 0 \ \text{ for } i \in \{1, \dots, n\},\ l \in \mathcal{J}.$$

Write $\Delta = \left(\begin{smallmatrix} \Delta_{11} & 0 \\ \Delta_{21} & \Delta_{22} \end{smallmatrix}\right)$ and $T^{-1} = \left(\begin{smallmatrix} T'_{11} & T'_{12} \\ T'_{21} & T'_{22} \end{smallmatrix}\right)$ in blocks. We claim that $u = \Delta_{11}$ is a matrix as Definition 2.1 asks for.

The determinant. As X is block upper triangular, $\det X = \det G^{\mathsf{T}} = \det G$; as Δ is block lower triangular, $\det X = \det T \cdot \det \Delta_{11} \cdot \det \Delta_{22}$. So $\det u$ divides $\det G$, which divides z.

The combinations. The first block row of $T^{-1}X = \Delta$ reads $T'_{11} = \Delta_{11}$ in the first block column and $-T'_{11}\mathbf{y} + T'_{12}\,G^{\mathsf{T}} = 0$ in the second, that is, $u\mathbf{y} = T'_{12}\,G^{\mathsf{T}}$. Hence, for $i = 1, \dots, n$ and $l \in \mathcal{J}$,

$$\sum_{i'=1}^{n} u_{ii'}\,(y_{i'})_l = \sum_{l' \in \mathcal{J}} (T'_{12})_{il'}\,G_{ll'},$$

that is, $\sum_{i'} u_{ii'} y_{i'} = G(t_i)$ for the vector $t_i = ((T'_{12})_{il'})_{l'}$ of $\mathcal{O}^{\mathcal{J}}$. It lies in $G(\mathcal{O}^{\mathcal{J}}) \subseteq B$. □

LEAN `IndexDvd.of_det_dvd` · `IsValuationPair.hermite` · `isValuationPair_top`

Remark 5.1 (comparison with the length of a quotient; not in the formal text)**.** Let $\mathcal{O}$ be a discrete valuation ring with uniformiser p, let A be a free $\mathcal{O}$-module of finite rank n and B a submodule of A with A/B of finite length $\operatorname{len}(A/B)$. Then, for z in $\mathcal{O}$: $[A : B] \mid z$ holds if and only if $p^{\operatorname{len}(A/B)}$ divides z. Indeed, B is free of rank n, so in a basis of A it is the image of a matrix G with $\det G$ a unit times $p^{\operatorname{len}(A/B)}$, and Theorem 2 gives one direction. Conversely, apply Definition 2.1 to a basis $y_1, \dots, y_n$ of A: if $z \neq 0$, the matrix u defines an injective endomorphism of A with image in B and cokernel of length the valuation of $\det u$, so $\operatorname{len}(A/B)$ is at most the valuation of z; and every power of p divides 0.

6 Where the results are used

Theorem 1 is used in one place, in the unit of the columns (unit 145), in a bound for the number of classes of standard definite spaces at the levels that contain a principal level: such a level has finite index in $\mathrm{U}_{\mathcal{J}}(\widehat{\mathcal{O}}_E)$, and the number of classes is at most that index times the bound of Theorem 1. That bound, and its corollary for the levels of the data, are used again in the unit of the columns and in the units of the rows and of the exchange (units 143 and 147), which belong to Theorem C of the write-up.

The index language is used in the units that prove Theorem A of the write-up. The determinant criterion is applied there with diagonal matrices (units 150 and 141); pull-back and push-forward transport index statements along the maps between spaces of forms (units 141 and 145); the lemma on finite sums is the step, in the unit of the endgame (unit 151), from one translate of a Poincaré series to finitely many, which is where the number of translates enters the index bound of Theorem A(b); and Proposition 4.7 adds the types of the operators attached to the marked primes (unit 145). Unit 144, on the elementary divisors of a Frobenius-twisted Hecke operator, uses Theorem 2, transitivity, push-forward and composition, and states its result with Definition 2.2.

7 Notes on the formal text

1. *The number of classes.* The formal statement of Theorem 1 bounds the cardinality of the set of classes as a natural number, which the library defines to be 0 for an infinite set. The formal proof bounds the cardinality as an extended natural number, through Input 3, and so proves that the set is finite; the statement does not say it.

2. *Letters.* The formal text calls the integer of Theorem 1 N and the index set n; here they are N' and $\mathcal{J}$, the letter N being kept in this write-up for the level. It writes K for a level and Φ for the places and their embeddings (here K, τ and ι_τ). The submodules that the formal text calls M, N, P, M' and (its own) N' are A, B, C, A', B' here; its modules V and U are V and V'; its scalar a is w; its linear maps f are G. In Proposition 4.7 the formal text writes z, s, T, t, L for what is here p, ν, (Y_i), (c_i) and the list.

3. *The arguments of the index relation.* The file declares M, N, z as implicit variables and then makes them explicit for this one definition. A reading of the text by program therefore lists each of the three twice. Lean takes each once, as an explicit argument: every use in the artifact gives exactly three arguments. This was not confirmed by asking Lean.

4. *Inferred types.* In the definition of the type the formal text does not write the types of p, of the submodule and of the exponent; Lean infers them. The uses (Proposition 4.7, where p is an element of the ring) show that p is a ring element and the exponent a natural number.

5. *Families of length zero.* Definition 2.1 quantifies over all n, including $n = 0$, where there is nothing to check. The families are indexed by $\{0, \dots, n-1\}$ in the formal text.

6. *Lemma 4.5.* Its hypothesis is asked for every i in $\mathcal{J}$, not only for those in $\mathcal{S}$, and $\mathcal{J}$ is an arbitrary set. The formal proof is one line of induction that calls push-forward and transitivity, as here.

7. *The injectivity step of Theorem 1.* The formal proof gives the rational unitary matrix and the integral adelic matrix as terms and leaves it to Lean to see that they relate the two representatives. The arrangement written above, $h_{\mathfrak{c}} = \gamma h_{\mathfrak{c}'} \kappa$ with $\gamma = L_{\mathfrak{c}} L_{\mathfrak{c}'}^{-1}$ and $\kappa = Q_{\mathfrak{c}'} Q_{\mathfrak{c}}^{-1}$, is read off these terms: the unitarity is proved for the product $L_{\mathfrak{c}} L_{\mathfrak{c}'}^{-1}$, and the integrality for the combination of the two instances of (1) displayed in the proof, which is $Q_{\mathfrak{c}'} Q_{\mathfrak{c}}^{-1}$. The library's lemma on double cosets, which fixes the order, was not opened: the library is not on the machine where this note was written.

8. *The size estimates.* The formal proof closes the two inequalities of the paragraph *Size* by automation. The intermediate bounds written there are ours; they were checked by hand.

9. *What an assembly assembles.* Lemma 4.6 is push-forward followed by transitivity, and Lemma 4.5 is an induction on these two; their content lies in Lemmas 4.3 and 4.4.

10. *The place of Theorem 1.* The header of its file counts it with the reduction theory of the background (Mahler and Godement compactness, finite covolume, adelic

Minkowski theorems), a known subject; it stands in this unit because its proof needs the count of Input 3, which belongs to the argument.

How this note was written. From the dossier of the unit: its eleven statement readings, its five structured proofs and the reader's list of doubts. The program check of the dossier covered 22 leaf steps of 5 proofs. A second reader compared the eleven readings with the Lean text and sampled the proofs; the remarks of that reading are taken up in the paragraph after Definition 2.1 and in the hypotheses of Theorem 2. I read both files of the unit completely, and in the background library the statements and definitions that the unit rests on: the unitary groups, the level subgroup, the rational points and the classes, the constant and the two lemmas of Inputs 1 and 2, the count of Input 3 with the variables of its file, the valuation pairs and the Hermite form. I did not read the proofs of the Inputs. The three lemmas without a structured proof (pull-back, inclusion, composition) and Lemma 4.5 were read in the source. The proofs above follow the formal ones; the proof of Theorem 2 writes out in blocks what the formal proof obtains by simplification, and Remark 5.1 is mine. Lean was not run for this note. An independent referee read the note against the Lean text; in the revision of 26 November 2026, after that report, three letters were changed (see the conventions), Input 4(b) received its proof, the comment on the Hermite form was corrected (row operations), the references for the Inputs were sorted, and the account of where Theorem 1 is used was completed.

In these texts `⊤` is the whole module, `⊔` the sum of submodules, `M.map y` the image and `p ^ n • M` the multiples; `Fin n` is the set $\{0, \dots, n-1\}$.

Notation

$\mathcal{O}$ a commutative ring; in Theorem 2 a valuation domain; $\mathcal{O}$ with a subscript is a ring of integers

V, V' $\mathcal{O}$-modules

A, B, C, A', B', A'_0 submodules

z, z', w; v elements of $\mathcal{O}$; an element of a module or of E

$[A : B] \mid z$ the index of B in A divides z (Definition 2.1)

n; $y_1, \dots, y_n$; y'_i, v_i, b_i, t_i the length of a family; a family of elements of a module; further elements

u, u', $u_{ii'}$ square matrices over $\mathcal{O}$ and their entries

i, i', l, l' indices; also natural numbers bounding exponents

G, G_i, G^{T} a linear map, also a square matrix; a family of linear maps; the transpose

p, ν, Y, c a ring element, a natural number, an endomorphism, a real number (Definition 2.2)

Y_i, c_i, Y', e, $\mathrm{len}(A/B)$ endomorphisms, real numbers; a composite; the length of a list; the length of a module of finite length

$\mathcal{J}$, $\mathcal{S}$, $\mathcal{S}'$, $\mathcal{S}_0$, $\#\mathcal{S}$ finite sets or sets of indices; the number of elements

$\mathcal{O}^{\mathcal{J}}$, $\mathrm{M}_{\mathcal{J}}(\mathcal{O})$, $\mathrm{GL}_{\mathcal{J}}(\mathcal{O})$ families, matrices and invertible matrices indexed by $\mathcal{J}$

E, $\mathcal{O}_E$, $\mathbb{A}_{E,f}$, $\widehat{\mathcal{O}}_E$ a CM field, its integers, its finite adeles, the integral adeles

τ, ι_τ, φ an infinite place; the embeddings of a CM type (in Input 3, chosen embeddings of a number field); a ring homomorphism to $\mathbb{C}$

N' an integer ≥ 1 in the different of E

$\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$, $\mathrm{U}_{\mathcal{J}}(E)$, $\mathrm{U}_{\mathcal{J}}(\widehat{\mathcal{O}_E})$ the unitary group of the standard form: adelic points, rational points, the stabiliser of the standard lattice

$\mathrm{Cl}(\mathsf{K})$, K the classes at level K; a subgroup of $\mathrm{U}_{\mathcal{J}}(\mathbb{A}_{E,f})$

$f(E)$ the number of infinite places of E

$c_{\mathrm{sb}}(E, \mathcal{J}, N')$ the constant $6N'(f(E) \cdot \#\mathcal{J})^2$

$\mathfrak{c}$, $\mathfrak{c}'$, $h_{\mathfrak{c}}$, h, h^* classes; a representative; an adelic matrix; the conjugate transpose

$L_{\mathfrak{c}}$, L, $Q_{\mathfrak{c}}$, $H_{\mathfrak{c}}$, $Z_{\mathfrak{c}}$ a short basis; $h_{\mathfrak{c}}^{-1} L_{\mathfrak{c}}$; the Gram matrix; the approximate inverse

ϱ, η, α, δ, z_τ the approximation map; an adele; an element of E; an element of the different; complex numbers

γ, κ a rational unitary matrix; an element of the level subgroup

E', F, ω in Input 3: a number field, a map, a bound; in Input 4, ω are weights

$\mathcal{A}$, $\mathcal{R}$, $\mathcal{K}$, $\mathcal{N}$, $\jmath$, ϵ in Input 4: a ring, a subring, finite sets, an injection, an idempotent

X, T, Δ, T'_{11}, Δ_{11}, $\mathbf{y}$ the matrix to be reduced, the transformation, the triangular form, their blocks; the matrix of the coordinates of a family

y, y', $\bar{v}$ in Input 4 two ring elements; the complex conjugate

N, M, K, Φ, P, U, a, f, s, t, L letters of the formal text, used only in the conventions and in §7, note 2

READBACK NOTE 35

Translates of Poincaré series fill the rows: the second moment over the level group and the filling theorem

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The rows of the proof are cusp forms on an indefinite unitary group; the columns are algebraic forms on a definite one, and a column gives a row by forming its Poincaré series along a Bessel subgroup. This note proves that the translates of these Poincaré series by the finite group of the chosen primes are *spread*: every subspace F of the rows is avoided, by some translate, on a share of the columns of nearly $\frac{1}{2}(1 - \dim F / \dim \text{rows})$. The proof is a second moment of Petersson type. The mean over the group of the squared Hilbert–Schmidt norm of the Gram operators of two translates is unfolded into sums of amplitudes over rational elements; its main term is bounded with constant 1 by a positive kernel of local Bessel integrals at finitely many primes and a sieve; a variance inequality turns the moment into the spreading statement. Theorem B of the handout follows from it by a greedy choice of translates.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, of the Riemann hypothesis and of its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles and that Lean's kernel accepted the proofs; an independent replay is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note (Note F of its unit) treats 18 of the 497 declarations of the unit *Translates of Poincaré series fill the rows*: the modules on fixed lines, on the finite system, on the moments, on the dimension of the rows and the filling theorem itself. Proved here from the inputs: Theorems A to D and the lemmas of §§4–9; two limiting arguments (in Proposition 4.5 and in Step 2 of the proof of Theorem D) are described and not written out. Taken for granted and stated as Inputs 1 to 10: the set-up of the unit with its amplitude sums and its crude estimate, the unfolding at finitely many places (Note G), the local theory at a finite place (Note T, with the facts on standard levels and on the tower method that it rests on), the sieve, a variance inequality of the unit on heights, the Petersson unfolding of Poincaré series, and classical facts from the artifact's background library (Siegel's formula in Weil's form, uniqueness of Haar measure, Harish-Chandra's formal degree). Every statement of this note was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 18 declarations.

1 The statements

The objects are defined or recalled in §2. In brief: D is admissible data for the parameters (Setting 2.5); $\mathrm{Col}(D)$ is the space of columns and $\mathrm{Row}(D)$ the space of rows; $\mathsf{G}(D)$ is the finite group of the chosen primes; $\mathcal{P}_D^\circ(\cdot)$ is the Poincaré series map from columns to forms of principal level (Definition 2.6); $\Pi_D(s)$ translates such a form by $s \in \mathsf{G}(D)$ and projects it to the rows; and $\mathrm{Ram}_D(\mathrm{Div}_N(D))$ is the operator on columns whose image is the space of ramified columns.

Theorem A (the filling theorem). *In Setting 2.5, let $c \in \mathbb{C}^\times$. For $s \in \mathsf{G}(D)$ let $B_s \colon \mathrm{Col}(D) \to \mathrm{Row}(D)$ be the linear map*

$$B_s(\psi) = \Pi_D(s)\Big(\mathcal{P}_D^\circ(c \cdot \mathrm{Ram}_D(\mathrm{Div}_N(D))\,\psi)\Big).$$

Then $\mathrm{Spread}((B_s)_{s\in\mathsf{G}(D)}; b(D)^{-2})$: for every complex subspace F of $\mathrm{Row}(D)$, with $\phi = \dim F / \dim \mathrm{Row}(D)$ (and $\phi = 0$ if $\dim \mathrm{Row}(D) = 0$), there is $s \in \mathsf{G}(D)$ such that

$$\dim B_s^{-1}(F) \;\le\; \Big(\frac{1+\phi}{2} + b(D)^{-2}\Big) \cdot \dim \mathrm{Col}(D).$$

LEAN `Data.ramifiedColumns_fill_rows`

Corollary 1.1 (rows exist)**.** *In Setting 2.5:* $\dim_{\mathbb{C}} \mathrm{Row}(D) \neq 0$.

LEAN `Data.finrank_rows_ne_zero`

Relation to the overview of the handout. The map $\mathcal{P}_D^\circ(\cdot)$ of this note is defined on all columns and involves no translation, no projection and no constant. The map that the overview writes $\mathcal{P}_D(\gamma)$, for $\gamma \in \mathsf{G}(D)$, from the ramified columns to the rows, is $\psi \mapsto \Pi_D(\gamma)(\mathcal{P}_D^\circ(c_0 \cdot \psi))$, where $c_0 \in \mathbb{C}^\times$ is the constant of the seesaw identity (unit on the seesaw). The ramified columns are the image of $\mathrm{Ram}_D(\mathrm{Div}_N(D))$; so the map B_s of Theorem A for $c = c_0$ is the overview's map $\mathcal{P}_D(s)$ composed with $\mathrm{Ram}_D(\mathrm{Div}_N(D))$, and Theorem A for $c = c_0$ gives Theorem B of the overview (§10).

Theorem A is the case, for the filling data $S(D)$ of the admissible data and the representation of $\mathsf{G}(D)$ on the forms of principal level, of the following statement about any unitary representation whose matrix coefficients on a family of vectors are amplitude sums.

Theorem B (filling, abstract form). *In Setting 2.1, suppose that E carries Weil data and that S is admissible. Let V be a finite-dimensional complex inner product space, ρ a representation of $\mathsf{G}(S)$ on V, let $Q\colon \ell^2(\mathrm{Cl}(S)\times \mathrm{Bc}(S)) \to V$ be a linear map, $g=(g_0,g_1)$ with $g_i \in \mathbb{C}[\mathsf{G}_i(S)]$, and c a real number. Suppose that*

(i) *ρ is unitary: $\langle \rho(s)x, \rho(s)y\rangle = \langle x, y\rangle$ for all s, x, y;*

(ii) *for all $s \in \mathsf{G}(S)$ and all pairs $x=(x_1,x_2)$, $y=(y_1,y_2)$ in $\mathrm{Cl}(S)\times \mathrm{Bc}(S)$,*

$$\big\langle \rho(s)\, Q(e_y),\, Q(e_x)\big\rangle = c\cdot A_S^{\mathrm{full}}(G_S(E); x_1, s, y_1)_{(x_2,y_2)},$$

where e_x is the vector of the standard basis at x;

(iii) *each g_i is a central idempotent, and $\mathrm{Re}\,(1-g_i)(1) \le b(S)^{-8}/2$ for $i=0,1$;*

(iv) *$0<c$; and $\dim \rho(g_0\otimes g_1)V \le \#\mathsf{G}(S)\cdot \deg(S)\cdot \mathrm{mass}(E, r(\mathfrak{s}))$.*

For $s\in\mathsf{G}(S)$ let $R_s\colon \ell^2(\mathrm{Cl}(S)\times\mathrm{Bc}(S)) \to \rho(g_0\otimes g_1)V$ be $R_s = \rho(g_0\otimes g_1)\circ\rho(s)\circ Q$. Then $\mathrm{Spread}((R_s)_{s\in\mathsf{G}(S)}; \frac{19}{2}\,b(S)^{-4})$: for every subspace F of $\rho(g_0\otimes g_1)V$, with $\phi = \dim F/\dim \rho(g_0\otimes g_1)V$, there is s with

$$\dim R_s^{-1}(F) \;\le\; \Big(\frac{1+\phi}{2} + \frac{19}{2}\,b(S)^{-4}\Big)\cdot \mathrm{cd}(S).$$

LEAN `Filling.Fits.exists_translate_finrank_comap_le`

Its proof rests on a second moment in which the constant of the main term is 1 up to $O(b(S)^{-4})$.

Theorem C (second moment with constant one). *In Setting 2.1, suppose that E carries Weil data and that S is admissible. Let V be a complex inner product space, $\Theta\colon \mathsf{G}(S)\to\mathbb{R}$ a function with $\Theta(s)\ge 0$ for all s, and $u\colon \mathsf{G}(S)\to V$ a family of vectors with $\langle u(a), u(b)\rangle = \Theta(a^{-1}b)$ for all a, b. Let $\Sigma \subseteq \mathrm{Ch}_0(S)$ be a set of chosen places above $q_0(S)$ and $\mathbf{d}$ frame-vector data for S (Definition 2.2). Suppose that*

$$\sum_{s\in\Omega}\Theta(s) \;\le\; \mathrm{En}_S(A_S^{\mathrm{full}}(G_S(E);\cdot,\cdot,\cdot);\Omega) \qquad \text{for every subset } \Omega\subseteq\mathsf{G}(S),$$

and that $\Theta(s)\neq 0$ implies $s\in \mathrm{Fix}_{S,w}(\mathbf{d}_w)$ for every $w\in\Sigma$. Then

$$\sum_{s\in\mathsf{G}(S)}\Theta(s) \;\le\; (1+9\,b(S)^{-4})\cdot \mathsf{d}(S)\cdot b(S)^{-6k(\mathfrak{s})\cdot\#\Sigma}.$$

LEAN `Filling.sum_le_of_positive_type`

Theorem D (the main-term estimate). *In Setting 2.1, suppose that E carries Weil data and that S is admissible. For every set $\Sigma\subseteq\mathrm{Ch}_0(S)$ of chosen places above $q_0(S)$ and all frame-vector data $\mathbf{d}$ for S,*

$$\begin{aligned}&\mathrm{En}_S(A_S^{\mathrm{full}}(G_S(E);\cdot,\cdot,\cdot);\mathrm{Fix}_S(\Sigma,\mathbf{d}))\\ &\quad\le\; (1-b(S)^{-4})(1+9\,b(S)^{-4})\cdot \mathsf{d}(S)\cdot b(S)^{-6k(\mathfrak{s})\cdot\#\Sigma}.\end{aligned}$$

LEAN `Filling.energy_fixingSet_le`

Here $\mathsf{d}(S) = \mathrm{cd}(S)^2/(\deg(S)\,\mathrm{mass}(E, r(\mathfrak{s})))$ is the expected value: the square of the number of columns divided by the expected number of rows per element of the group. For $\Sigma = \emptyset$ Theorem C says that the sum over the whole group of the squared Hilbert–Schmidt norms of the amplitude sums exceeds this by a factor $1 + 9\,b(S)^{-4}$ at most; each chosen place at which the summand is forced to fix a line gains a further factor $b(S)^{-6k(\mathfrak{s})}$. The chain of the proof is

$$\text{Theorem D} \implies \text{Theorem C} \implies \text{Theorem B} \implies \text{Theorem A},$$

and Theorem D itself combines the crude estimate of the unit (Input 3), the unfolding of the main terms into local correlations (Input 4), a one-sided form of Siegel's formula at finitely many places (Proposition 4.5), the domination by the top kernel (Proposition 4.6) and the sieve (Input 6) applied to a finite sieve system (Proposition 4.7).

2 The setting

Conventions. The natural numbers are $0, 1, 2, \ldots$. E is a CM field with its CM type: a number field that is a CM field, with complex conjugation $x \mapsto \bar{x}$, together with the choice of one embedding at each infinite place τ; $x_\tau \in \mathbb{C}$ is the image of $x \in E$ under it, and $f(E)$ is the number of infinite places. A *finite place* w of E is a non-zero prime ideal; $\mathbb{F}_w$ is its residue field, E_w the completion, $\bar{w}$ the conjugate place. $\mathbb{A}_{E,f}$ is the ring of finite adeles and $\hat{O}_E$ its subring of integral adeles. The field E is *stably unramified* if it contains a primitive root of unity of order 5040, and E *carries Weil data* if it is stably unramified and a splitting character in the sense of Chapter III of the handout is given. A *shape* is a triple $\mathfrak{s} = (\varrho, \kappa, k_0)$ of a natural number, a finite set and an element of it; we write $\varrho(\mathfrak{s})$, $k(\mathfrak{s}) = \#\kappa$, $n(\mathfrak{s}) = \varrho(\mathfrak{s}) + 1$ and $r(\mathfrak{s}) = 2\varrho(\mathfrak{s}) + k(\mathfrak{s}) + 1$. For a commutative ring with involution, X^* is the conjugate transpose of a matrix X. A *semilocal field* A is a commutative topological ring with a Haar measure vol in the sense of the background library (here always a finite product of completions of E); with an involution, an *integral place structure* on it provides a ring of integers O_A of volume 1, with unit group $O_A^\times$, a unitary additive character ψ_A and a modulus mod_A; the place structure is never called P. Index sets written n, j, ι are finite sets or arbitrary sets as stated. For a finite group G, $\mathbb{C}[G]$ is the complex group algebra and $x(s)$ the coefficient of $x \in \mathbb{C}[G]$ at $s \in G$; x is a *central idempotent* if $x^2 = x$ and $s \mapsto x(s)$ is a class function. A complex *inner product space* V has the inner product $\langle \cdot, \cdot \rangle$, conjugate-linear in the first variable, and is *finite-dimensional* where this is said. Integrals of functions with values in $[0, \infty]$ are Lebesgue integrals. P denotes the parameters of the proof (Chapter III), and the letters T, T_0 of the formal text for sets of places are written T, T_0; F, a level in the formal text, is written $\mathcal{L}$, and Z is an intermediate group of it. A *side* is one of the two words full, cut. Four letters have in this note a meaning other than in the handout's overview, and each use says which: c, c' are classes of the filling data, and c is also the scalar of Theorem A and the constant of Theorem B; s, t are elements of the finite group of the chosen places (the complex variable does not occur); μ is a measure (the exponent of the data does not occur); and $\zeta_{\hat{O}_E}$ is the ideal zeta function of the integral adeles (Riemann's zeta function does not occur).

Setting 2.1 (filling data)**.** E is a CM field with its CM type, $\mathfrak{s}$ is a shape, and S is filling data over E of shape $\mathfrak{s}$, in the sense of the set-up of this unit. Its components and the facts about them that this note uses are:

(i) a real number $b(S) \geq 1000$; a prime number $N(S) \geq 5$ and a finite idele $\bar{\pi}(S) \in \hat{O}_E$ with $\bar{\pi}(S)\,\overline{\bar{\pi}(S)} = N(S)$ (the bar in $\bar{\pi}(S)$ is part of the name of this idele, as in the formal text, and not a conjugation; its conjugate is $\overline{\bar{\pi}(S)}$); two primes $q_0(S)$, $q_1(S)$ different from $N(S)$ with $b(S)^{10} \leq q_i(S) \leq b(S)^{11}$, and $g(S) = q_0(S)q_1(S)$, with $b(S)^{19} \leq g(S) \leq b(S)^{23}$ (two further conditions of the formal record; they follow from the bounds for the primes, which give $b(S)^{20} \leq g(S) \leq b(S)^{22}$);

(ii) for $i = 0, 1$ a set $\mathrm{Ch}_i(S)$ of $f(E)$ finite places above $q_i(S)$, the *chosen places*, with residue fields of $q_i(S)$ elements, such that the conjugate of a chosen place is never chosen, and an integral finite adele r is divisible by $g(S)$ exactly if r and $\bar{r}$ vanish modulo every chosen place;

(iii) a generator $\varpi(S)$ of the different of E with $\overline{\varpi(S)} = -\varpi(S)$; an open compact subgroup $K^{\mathrm{col}}(S)$ of the finite adelic unitary group of the standard hermitian form on κ (the *column level*), with trivial class automorphism groups; for every infinite place τ a Bessel system $\mathfrak{B}_\tau(S)$ on the real group, with a finite index set, a full and a cut Bessel function, a representation and a positive number, its degree;

(iv) the inequalities $10^5 \leq \varrho(\mathfrak{s})$, $2^{-\varrho(\mathfrak{s})} \leq b(S)^{-6}$, $n(\mathfrak{s})\,[E:\mathbb{Q}] \leq 2^{2\varrho(\mathfrak{s})}$, $1000\,(2\varrho(\mathfrak{s}) + 2) \leq k(\mathfrak{s}) \leq f(E) \leq b(S)/1000$, $k(\mathfrak{s}) \leq b(S)$, and the chain $10^{10} n(\mathfrak{s})^4 \leq n(\mathfrak{s})^6$, $3\,n(\mathfrak{s})^6 + 12 \leq n(\mathfrak{s})^7 \leq k(\mathfrak{s})$.

Forms and groups. These notions belong to the background library and to the set-up of this unit; they are recalled with their arguments. The index set $I(\mathfrak{s})$ consists of $e_0, \dots, e_{\varrho(\mathfrak{s})-1}$, of the elements of κ, of z, and of $e_0^*, \dots, e_{\varrho(\mathfrak{s})-1}^*$; $M(\mathfrak{s}) = \kappa \sqcup \{z\}$. The *frame* is $\mathfrak{f}_a = e_a$ for $a < \varrho(\mathfrak{s})$ and $\mathfrak{f}_{\varrho(\mathfrak{s})} = z$. For a commutative ring R with involution, an $\mathfrak{s}$*-form* over R is a hermitian matrix T indexed by $M(\mathfrak{s})$; its *split Gram matrix* $J(T)$, indexed by $I(\mathfrak{s})$, pairs e_a with e_a^* to 1 and is T on the middle; $G(T)$ is the unitary group of $J(T)$ over R and $h_T(v, v') = v^* J(T) v'$. For $g \in G(T)$, $Z_T(g) = (h_T(\mathfrak{f}_a, g\,\mathfrak{f}_{a'}))_{a,a' \leq \varrho(\mathfrak{s})}$ is its frame Gram matrix. In $G(T)$: $\mathcal{H}(T)$ is the subgroup of the elements that fix all e_a, all e_a^* and z; $\mathcal{H}_\varrho(T)$ the subgroup of those that fix all e_a and e_a^*; $\mathcal{U}(T)$ is the Bessel unipotent subgroup of the library and $\mathcal{S}(T) = \mathcal{U}(T)\,\mathcal{H}(T)$ the *Bessel subgroup*: an element s lies in $\mathcal{S}(T)$ exactly if, for every a, $s\,\mathfrak{f}_a - \mathfrak{f}_a$ lies in the span of the $\mathfrak{f}_{a'}$ with $a' < a$. For $u \in \mathcal{U}(T)$, $\mathrm{sd}(u)$ is the sum of the entries of u just above the diagonal of its frame block. For a family $p = (p_0, p_1, \dots)$ of units of R, $w_\varrho(p) \in G(T)$ is the Weyl element of length $\varrho(\mathfrak{s})$: it sends e_a to $p_a e_a^*$ and e_a^* to $\bar{p}_a^{-1} e_a$ for $a < \varrho(\mathfrak{s})$, and fixes the middle; for $p\colon \{0, \dots, \varrho(\mathfrak{s}) - 1\} \to R^\times$ and a unit t, $(p \,|\, t)$ is the sequence $p_0, \dots, p_{\varrho(\mathfrak{s})-1}, t, 1, 1, \dots$.

In Setting 2.1: $T_S^{\mathrm{rat}}(R)$ is the $\mathfrak{s}$-form over R that is the identity on κ and $-N(S)$ at z, and $G_S(R) = G(T_S^{\mathrm{rat}}(R))$; $T_S^{\mathrm{lat}}(R)$ is the Gram matrix of the same hermitian form in the *lattice basis*, in which the basis vector x_{k_0} of k_0 is replaced by $\overline{\bar{\pi}(S)}^{-1} x_{k_0} + N(S)^{-1} z$ (for a unit π of another ring in the place of $\bar{\pi}(S)$: by $\bar{\pi}^{-1} x_{k_0} + (\pi\bar{\pi})^{-1} z$); $\Lambda(S)$ is the matrix of this change of basis over $\mathbb{A}_{E,f}$, and $G_S^{\mathrm{lat}} = G(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$. The homomorphism $\mathrm{r}_S^f\colon G_S(E) \to G_S^{\mathrm{lat}}$ is the diagonal em-

bedding followed by the change of basis, $\mathrm{r}_S^\infty \colon G_S(E) \to \prod_\tau G_1(\mathfrak{s})$ is the family of the images at the infinite places, rescaled to the real form $G_1(\mathfrak{s})$ of the library, and inc_S embeds the finite adelic points of the unitary group of the standard form on κ into G_S^{lat} as $\mathcal{H}$. For $\gamma \in G_S(E)$, $Z_S(\gamma) = Z_{T_S^{\mathrm{rat}}(E)}(\gamma)$ and $\mathsf{g}_S(\gamma)$ is the *term discriminant*, formed from the last two leading minors of $Z_S(\gamma)$.

$K(S) \subseteq G_S^{\mathrm{lat}}$ is the subgroup of the elements that are integral with integral inverse; the finite group of the chosen places is

$$\mathsf{G}(S) = \mathsf{G}_0(S) \times \mathsf{G}_1(S), \qquad \mathsf{G}_i(S) = \prod_{w \in \mathrm{Ch}_i(S)} \mathrm{GL}_{I(\mathfrak{s})}(\mathbb{F}_w),$$

with $\iota_i \colon \mathsf{G}_i(S) \to \mathsf{G}(S)$ the inclusion of the i-th factor; $\mathrm{red}_S \colon K(S) \to \mathsf{G}(S)$ reduces the entries modulo the chosen places, $K_g(S)$ is its kernel, and for a subgroup B of G_S^{lat}, $\overline{B}^{S} = \mathrm{red}_S(B \cap K(S))$. $\hat{g}(S)$ is the integer $g(S)$ as a finite idele, and $\psi_S^{\mathcal{U}}(u) = \psi_f(-\mathrm{sd}(u)/(g(S)\varpi(S)))$ for $u \in G_S^{\mathrm{lat}}$, with ψ_f the standard additive character of $\mathbb{A}_{E,f}$. $\mathrm{Cl}(S)$ is the finite set of double cosets of the finite adelic unitary group of κ by its rational points and $K^{\mathrm{col}}(S)$; each class c has a chosen representative, and $h_S(c)$ is its image under inc_S. For classes c, c' and $\gamma \in G_S(E)$,

$$\mathrm{pos}_S(c, c'; \gamma) = h_S(c)^{-1}\, \mathrm{r}_S^f(\gamma)\, h_S(c') \in G_S^{\mathrm{lat}},$$

and for $s \in \mathsf{G}(S)$ the set of *terms over* (c, s, c') is $\mathrm{Tm}_S(c, s, c') = \{\gamma \in G_S(E) : \mathrm{pos}_S(c, c'; \gamma) \in K(S),\ \mathrm{red}_S(\mathrm{pos}_S(c, c'; \gamma)) = s\}$. A set $\Xi \subseteq G_S(E)$ is *stable* if $u^{-1}\gamma u' \in \Xi \iff \gamma \in \Xi$ for all rational $u, u' \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$. $\mathcal{U}_{S,c}$ is the group of the rational $u \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$ with $\mathrm{pos}_S(c, c; u) \in K_g(S)$.

Amplitudes, energies, constants. $\mathrm{Bc}(S)$ is the set of the families $(i_\tau)_\tau$ of indices of the Bessel systems. For a side σ, a point y of $\prod_\tau G_1(\mathfrak{s})$ and $i \in \mathrm{Bc}(S)$, $W_S^\sigma(y)_i$ is the product over τ of the i_τ-th coordinates at y_τ of the full or the cut Bessel function of $\mathfrak{B}_\tau(S)$. With the cutoffs $\beta_{S,c}$ of the set-up, the *amplitude* of $\gamma \in G_S(E)$ over c, c' is the vector of $\ell^2(\mathrm{Bc}(S) \times \mathrm{Bc}(S))$

$$a_S^\sigma(c, c'; \gamma)_{(i,i')} = \int \beta_{S,c}(y)\, \beta_{S,c'}(\mathrm{r}_S^\infty(\gamma)^{-1} y)\, W_S^\sigma(y)_i\, \overline{W_S^\sigma(\mathrm{r}_S^\infty(\gamma)^{-1} y)_{i'}}\, dy,$$

and for $\Xi \subseteq G_S(E)$ the *amplitude sum* is

$$A_S^\sigma(\Xi; c, s, c') = \sum_{\gamma \in \Xi \cap \mathrm{Tm}_S(c,s,c')} a_S^\sigma(c, c'; \gamma).$$

For a family $A(c, s, c')$ of vectors of a normed space and $\Omega \subseteq \mathsf{G}(S)$, its *energy* is

$$\mathrm{En}_S(A; \Omega) = \nu(S)^{-2} \sum_{c, c' \in \mathrm{Cl}(S)} \sum_{s \in \Omega} \|A(c, s, c')\|^2.$$

The constants of the set-up are: the covolume $\nu(S) > 0$; $\mathrm{cd}(S) = \#\mathrm{Cl}(S) \cdot \#\mathrm{Bc}(S)$; $\deg(S)$, the product of the degrees of the Bessel systems; the mass $\mathrm{mass}(E, r(\mathfrak{s}))$ of the genus of the standard hermitian lattice of rank $r(\mathfrak{s})$ over E; and

$$\mathsf{d}(S) = \frac{\mathrm{cd}(S)^2}{\deg(S)\ \mathrm{mass}(E, r(\mathfrak{s}))}, \qquad \mathsf{d}_1(S) = \#\overline{\mathcal{S}}^{S} \cdot \mathrm{cd}(S), \qquad \mathrm{tl}(S) = b(S)^{k(\mathfrak{s}) f(E)/4},$$

where $\overline{\mathcal{S}}^{S}$ is formed with $\mathcal{S} = \mathcal{S}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$; further the codimension factor and the order

$$\mathrm{cf}(S) = (b(S)/g(S))^{k(\mathfrak{s})f(E)} \cdot 2\,\mathrm{tl}(S)^2, \qquad \mathrm{uo}(S) = g(S)^{f(E)\varrho(\mathfrak{s})(2k(\mathfrak{s})+2\varrho(\mathfrak{s})+1)},$$

Siegel's constant

$$c_*(S) = \Big(\frac{\pi^{k(\mathfrak{s})}}{(k(\mathfrak{s})-1)!\,N(S)^{k(\mathfrak{s})}}\Big)^{f(E)} |d_E|^{1/4}\ \mathrm{vol}(\hat{O}_E)^{k(\mathfrak{s})}$$

(with d_E the discriminant of E and $\mathrm{vol}(\hat{O}_E)$ the volume of the integral adeles for the self-dual measure), the packet constant $a_*(S) = \#\overline{\mathcal{S}}^{S} \cdot \mathrm{uo}(S) \cdot \#\mathrm{Cl}(S) \cdot c_*(S)$, the frame scales $\mathrm{fs}_S(\tau, a) = \kappa_\tau(S)^{2(\varrho(\mathfrak{s})-a)}/N(S) > 0$ for $a \le \varrho(\mathfrak{s})$, where $\kappa_\tau(S)$ is the real part of $g(S)\,\varpi(S)_\tau/(2\pi i)$ (in particular $\mathrm{fs}_S(\tau, \varrho(\mathfrak{s})) = N(S)^{-1}$), with their product $\mathrm{fs}(S)$, and the constant $\mathrm{oc}(\mathfrak{s}) > 0$ of the open cell.

S is *admissible* if the standing hypotheses of the set-up hold. This note uses these of them: $K^{\mathrm{col}}(S) = \mathrm{inc}_S^{-1}(K_g(S))$; red_S is surjective; and

$$\mathrm{tl}(S)^{44}\,\mathsf{d}_1(S) \le \mathsf{d}(S), \qquad \mathrm{tl}(S)^{18}\,\mathrm{cf}(S)\,\mathsf{d}(S) \le \mathsf{d}_1(S),$$
$$a_*(S) \ \le\ (1 + b(S)^{-9})\,\mathsf{d}(S)\ \deg(S)\ \frac{\mathrm{oc}(\mathfrak{s})^{f(E)}}{\mathrm{vol}(\hat{O}_E)^{n(\mathfrak{s})}}\Big(\frac{\nu(S)\,\mathrm{fs}(S)}{\#\mathrm{Bc}(S)}\Big)^2.$$

Definition 2.2 (fixing sets; recalled from the set-up)**.** In Setting 2.1. *Frame-vector data* $\mathbf{d}$ for S assign to every $w \in \mathrm{Ch}_0(S)$ a pair $\mathbf{d}_w = (\epsilon_w, v_w)$ of a Boolean and a non-zero vector $v_w \in \mathbb{F}_w^{\{0,\dots,\varrho(\mathfrak{s})\}}$; the same word is used for a single pair at a place of $\mathrm{Ch}_i(S)$. For $w \in \mathrm{Ch}_i(S)$ and such a pair (ϵ, v), $\mathrm{Fix}_{S,w}((\epsilon, v))$ is the subgroup of the $s \in \mathsf{G}(S)$ for which $s_w^{(\epsilon)}$ fixes the vector $\sum_a v_a \mathfrak{f}_a$ of $\mathbb{F}_w^{I(\mathfrak{s})}$, where $s_w^{(\epsilon)} = s_w$ if ϵ is false and $s_w^{(\epsilon)} = J^{-1}(s_w^{-1})^t J$ if ϵ is true, J being the split Gram matrix of $T_S^{\mathrm{lat}}(\mathbb{F}_w)$. For a natural number X, s *fixes norm at least* X if there is a finite set of triples (i, w, ϵ), $w \in \mathrm{Ch}_i(S)$, with $X \le \prod q_i(S)$ over the set, such that for each of them $s \in \mathrm{Fix}_{S,w}((\epsilon, v))$ for some $v \ne 0$. For $\Sigma \subseteq \mathrm{Ch}_0(S)$ and frame-vector data $\mathbf{d}$, $\mathrm{Fix}_S(\Sigma, \mathbf{d})$ is the set of the $s \in \mathsf{G}(S)$ such that $s \in \mathrm{Fix}_{S,w}(\mathbf{d}_w)$ for every $w \in \Sigma$, and such that $\Sigma = \mathrm{Ch}_0(S)$ or, for some $w \in \mathrm{Ch}_0(S)$, all leading minors of the frame Gram matrix $Z_{T_S^{\mathrm{lat}}(\mathbb{F}_w)}(s_w)$ are non-zero.

Levels at finitely many places. For a finite set T of finite places, $E_{\mathsf{T}} = \prod_{w \in \mathsf{T}} E_w$; $x_{\mathsf{T}} \in E_{\mathsf{T}}$ is the family of the components at T of a finite adele x, or of an element of E; x is *integral off* T if its components at the places outside T are integral, and an element of G_S^{lat} is integral off T if its entries and those of its inverse are. The homomorphism $\mathrm{loc}_{S,\mathsf{T}} \colon G_S^{\mathrm{lat}} \to G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ takes components at T. When E_{T} carries an integral place structure, O_{T} is its ring of integers and, for a unit u of E_{T}, $K_{S,\mathsf{T}}(u)$ is the group of the $y \in G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ that are integral with integral inverse and congruent to 1 modulo u; so $K_{S,\mathsf{T}}(1)$ is the integral unitary group.

A *level* $\mathcal{L}$ of $T_S^{\mathrm{lat}}(E_{\mathsf{T}})$, in the sense of the unit on the real place, consists of a hyperbolic basis of the middle form with an orthonormal part, a unit $g_{\mathcal{L}}$ and measures on the floors of the tower $\mathcal{H}_0 \supseteq \cdots \supseteq \mathcal{H}_\varrho \supseteq \mathcal{H}$; of these this note uses the measure $\mathsf{M}(\mathcal{L})$ on $G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$, which for a standard level is a Haar measure (Input 10(a)), the measure $\theta_n(\mathcal{L})$ on $\mathcal{H}$, the measure $\mu_{\varrho,2}^{\mathcal{L}}$ on $\mathcal{H}_\varrho$ and the measure *quadric measure* $\delta^{(\varrho)}(\mathcal{L})$ (written so in Note T and in the set-up) on the vectors e of $E_{\mathsf{T}}^{I(\mathfrak{s})}$ in the orbit

of z (the quadric $h(e,e) = -N(S)$). Following Note G, $\mathcal{L} \in \mathrm{FL}(S, \mathsf{T})$ ($\mathcal{L}$ *is a filling level for* S *at* T) means: $\mathcal{L}$ is a standard level with $3\varrho(\mathfrak{s}) + 6$ further hyperbolic pairs and an orthonormal part of size $k(\mathfrak{s}) - 6\varrho(\mathfrak{s}) - 13$; the character of the place structure is $\psi_{S,\mathsf{T}}(x) = \psi_f(-\tilde{x}/\varpi(S))$, $\tilde{x}$ the extension of x by zero; and $g_{\mathcal{L}} = \hat{g}(S)_{\mathsf{T}}$. Then the congruence group of $\mathcal{L}$ is $K_{S,\mathsf{T}}(g_{\mathcal{L}})$.

Setting 2.3 (a filling level)**.** In Setting 2.1, with E, $\mathfrak{s}$ and S as there: T is a finite set of finite places of E that is stable under complex conjugation; E_{T} carries an integral place structure; and $\mathcal{L}$ is a level of $T^{\mathrm{lat}}_S(E_{\mathsf{T}})$ with $\mathcal{L} \in \mathrm{FL}(S, \mathsf{T})$, a filling level.

In Setting 2.3 the following objects of Note T are used; y, x, l are elements of $G(T^{\mathrm{lat}}_S(E_{\mathsf{T}}))$.

(a) The *finite Bessel function*: for a unit g, $\chi_g(y) = \psi_{\mathsf{T}}(g^{-1}\,\mathrm{sd}(u))$ if $y \in u\,K_{S,\mathsf{T}}(g)$ with $u \in \mathcal{U}$, and $\chi_g(y) = 0$ if there is no such u.

(b) $\mathrm{Int}(\mathcal{L})$ is the set of the subgroups Z with $K_{S,\mathsf{T}}(g_{\mathcal{L}}) \le Z \le K_{S,\mathsf{T}}(1)$, the *intermediate groups*; $\mathrm{Cos}(Z)$ is the set of the cosets of $K_{S,\mathsf{T}}(g_{\mathcal{L}})$ in Z, each with a representative a_c; $\mathsf{v}(\mathcal{L})$ is the product of the floor moduli of $\mathcal{L}$ below ϱ, and

$$\mathrm{mr}(Z) = \mathsf{M}(\mathcal{L})(Z) \cdot \mathsf{M}(\mathcal{L})(K_{S,\mathsf{T}}(g_{\mathcal{L}})) \cdot \mathsf{v}(\mathcal{L})^{-2},$$
$$\mathcal{J}_0(\mathcal{L}; Z) = \int \Big| \int_Z \chi_{g_{\mathcal{L}}}(yxy^{-1})\, d\mathsf{M}(\mathcal{L})(y) \Big|^2 d\mathsf{M}(\mathcal{L})(x).$$

(c) The *finite Bessel vector* $W_Z(y) \in \ell^2(\mathrm{Cos}(Z))$ has the coordinate $\chi_{g_{\mathcal{L}}}(y\,a_c^{-1})$ at the coset c.

(d) For measures and vector-valued functions, $\mathrm{J}(\mu, W; \gamma)$ is the tensor with coordinates $\int W(y)_i\, \overline{W(\gamma^{-1}y)_{i'}}\, d\mu(y)$. For a sequence p of units of E_{T}, the *correlation* is $\mathcal{J}(Z; p, l) = \mathsf{h}_{\varrho}(\mathcal{L}; p, 1) \cdot \mathrm{J}(\mathsf{M}(\mathcal{L}), W_Z(\cdot); w_{\varrho}(p)\, l^{-1})$, where $\mathsf{h}_{\varrho}(\mathcal{L}; p, 1)$ is the head density of the unit on the real place; for $L \subseteq E_{\mathsf{T}}$ and sequences p, q the *top kernel* is

$$\mathcal{K}(L; Z; p, q) = \int_{\{l \in \mathcal{H}_{\varrho}:\ h(z, l^{-1}z) - p_{\varrho} \in L\}} \big\langle \mathcal{J}(Z; p, l), \mathcal{J}(Z; q, l) \big\rangle\, d\mu^{\mathcal{L}}_{\varrho,2}(l);$$

and for a complex matrix R and a family ω of sequences of units, both indexed by a finite set, and a vector e, the *energy* $\mathcal{E}(Z; R, \omega, e)$ is the infimum over the $l \in \mathcal{H}_{\varrho}$ with $l^{-1}z = e$ of $\int \sum_x (\mathrm{Re}\ v^* R v)^+\, d\theta_n(\mathcal{L})(h)$, where $v_p = \mathcal{J}(Z; \omega_p, hl)_x$ and x runs over $\mathrm{Cos}(Z) \times \mathrm{Cos}(Z)$.

(e) For $j \le \varrho(\mathfrak{s})$, sequences p, q, a vector-valued function W and a function ω, $\mathcal{I}_j(\mathcal{L}; p, q; W, \omega) \in \mathbb{C}$ is the floor form of the unit on the real place, and for a natural number K, $\Lambda_K(j; p) = \prod_{l<j} [p_0 \cdots p_l\,]^{K/2}$ if all the partial products are integral, and 0 otherwise, where $[\xi]$ is the generalised index of ξ, equal to the index of ξO_{T} in O_{T} for integral ξ; $\mathrm{den}(\xi)$ is the index of $O_{\mathsf{T}} \cap \xi^{-1} O_{\mathsf{T}}$ in O_{T}.

The *coset amplitude* of Note G, for a side σ, classes c, c', $s \in \mathsf{G}(S)$ and $\gamma \in G_S(E)$, is

$$a^{\sigma}_{S,\mathsf{T}}(c, s, c'; \gamma) = \sum_{(u,u')} a^{\sigma}_S(c, c'; u\gamma u'^{-1}),$$

the sum over the pairs of rational elements of $\mathcal{U}(T^{\mathrm{rat}}_S(E))$ with $\mathrm{pos}_S(c, c; u)$ integral off T and $u\gamma u'^{-1} \in \mathrm{Tm}_S(c, s, c')$. The *frequency gain* of the set-up is $\beta_{S,\mathsf{T}}(\xi) = [\xi]^{(k(\mathfrak{s}) - n(\mathfrak{s})^7)/2}\, \mathrm{den}(\xi)^{-6}\, b(S)^{n(\mathfrak{s})^9 f(E)}$ for $\xi \in E_{\mathsf{T}}$.

Definition 2.4 (sieve systems; recalled from the set-up)**.** Let C be a commutative ring with a measure, U a topological space, $u\colon C \to U$ and $\iota_U\colon U \to C$ maps, n a natural number, $J(i,p,q) \in \mathbb{C}$ a function of a natural number and two sequences in U, $\psi\colon C \to \mathbb{C}$, $\mathcal{E}_0$ a real number, $\Lambda(i,p)$ and $\beta(\xi)$ real functions. These data form a *sieve system* of depth n if: $\psi(0) = 1$; for $i \le n$, all p, q and $\xi \in C$, the function $f(c) = \psi(\xi c)\, J(i+1, p[i \mapsto u(c)], q[i \mapsto u(c)])$ is integrable, $\int f = J(i,p,q)$ if $\xi = 0$, and $|\int f| \le \beta(\xi)\Lambda(i,p)\Lambda(i,q)$ if ξ is a unit; for every finite family of sequences with a common n-th term the matrix of the values of $J(n+1,\cdot,\cdot)$ is positive semidefinite; $J(n+1,\cdot,\cdot)$ is continuous; $|J(0,p,q)| \le \mathcal{E}_0$; and for $i < n$, if $\xi = \iota_U(p_i) - \iota_U(q_i)$ is a unit, then $|J(i+1,p,q)| \le \beta(\xi)\Lambda(i+1,p)\Lambda(i+1,q)$.

Setting 2.5 (the admissible data)**.** $P = (N_0, d)$ are the parameters of the proof and D is admissible data for P (Chapter III of the handout; Setting 1 of its overview). Attached to D are, as in the note *Good forms and rows*: the CM field $E(D)$, the ranks $m(D)$, $r(D)$, $k(D)$, the third scale $b(D)$, the level $N(D)$, a prime, with an integer $\pi_N(D)$ of $E(D)$ such that $\pi_N(D)\overline{\pi_N(D)} = N(D)$; the finite group $\mathsf{G}(D)$ of the chosen primes; the space $Y_0(D)$; the space $\mathrm{Prin}(D, Y_0(D))$ of the forms of principal level with the representation $\mathrm{rep}_{D,Y_0(D)}$ of $\mathsf{G}(D)$; the good idempotent $e_0(D) \in \mathbb{C}[\mathsf{G}(D)]$; and the rows $\mathrm{Row}(D)$, the image of $e_0(D)$ on $\mathrm{Prin}(D, Y_0(D))$. From the same note and from the units on the rows and on the exchange, for §9: the hermitian space $W_{m(D)}(D)$ of rank $r(D)$ that carries the good forms; the finite set $I(D)$ of the row indices, of $r(D)$ elements, with its numbering $\mathrm{num}_D\colon I(D) \to \{0, \dots, r(D)-1\}$; for every infinite place τ the row parameter $\varkappa_D(\tau,\cdot)$, a real function on $\{0,\dots,r(D)-1\}$; the gap $h(D)$ of the doubled row parameters; and, in the finite adelic unitary group of $W_{m(D)}(D)$, the maximal level K_0 and inside it the principal level $K_g(D)$ at the chosen primes. From the units on the columns and on the seesaw: the space $\mathrm{Col}(D)$ of columns; the set $\mathrm{Div}_N(D)$ of the primes of $E(D)$ that divide $\pi_N(D)$; for $w \in \mathrm{Div}_N(D)$ a central element $\epsilon_D(w)$, a norm-one integral finite idele that is 1 away from w and $\bar{w}$; for $\mathcal{W} \subseteq \mathrm{Div}_N(D)$ the operator

$$\mathrm{Ram}_D(\mathcal{W}) = \prod_{w \in \mathcal{W}} (1 - \text{translation by } \epsilon_D(w)) \quad \text{on } \mathrm{Col}(D);$$

for $s \in \mathsf{G}(D)$ the map $\Pi_D(s)\colon \mathrm{Prin}(D, Y_0(D)) \to \mathrm{Row}(D)$,

$$\Pi_D(s)(y) = \#\mathsf{G}(D) \cdot e_0(D)(\mathrm{rep}_{D,Y_0(D)}(s)\, y);$$

the filling data $S(D)$ of D (Note G), which are filling data over $E(D)$ whose group $\mathsf{G}(S(D))$ is identified with $\mathsf{G}(D)$; and the linear isomorphism $\mathrm{cc}_D\colon \mathrm{Col}(D) \to \ell^2(\mathrm{Cl}(S(D)) \times \mathrm{Bc}(S(D)))$ of column coordinates.

For a family $(B_s)_{s\in\mathcal{G}}$ of linear maps from a finite-dimensional complex space X to a complex space Y and a real number η, the unit on heights writes $\mathrm{Spread}((B_s)_{s\in\mathcal{G}}; \eta)$ (*the family is spread with defect* η) if for every subspace F of Y, with $\phi = \dim F / \dim Y$ (read as 0 when $\dim Y = 0$), there is s with $\dim B_s^{-1}(F) \le ((1+\phi)/2 + \eta)\dim X$.

Definition 2.6 (the Poincaré series map)**.** In Setting 2.5, for a column $\psi \in \mathrm{Col}(D)$,

$$\mathcal{P}^\circ_D(\psi) = \mathcal{P}^{\mathrm{fit}}_{S(D)}(\mathrm{cc}_D(\psi)) \;\in\; \mathrm{Prin}(D, Y_0(D)),$$

where $\mathcal{P}^{\mathrm{fit}}_{S(D)}$ is the Poincaré series map of the set-up for the filling data $S(D)$, which fit the space $Y_0(D)$: it sends the basis vector at $(c,i) \in \mathrm{Cl}(S(D)) \times \mathrm{Bc}(S(D))$ to the

form $\sum_\gamma \beta_{c,i}(\gamma\,\cdot)$, the sum over the rational points of the unitary group of $Y_0(D)$, of the cut Bessel function $\beta_{c,i}$ attached to the class c and the coordinate i. The map $\psi \mapsto \mathcal{P}_D^\circ(\psi)$ is $\mathbb{C}$-linear.

LEAN `Data.poincare`

3 What is taken for granted

The following statements are used and not proved here. Each was compared with its Lean statement. Inputs 1 to 3 and 6 belong to the set-up of this unit (chunks a and b of its dossier, the subject of other notes of the unit), Input 4 to Note G of this unit (*From amplitude sums to local correlations*), Input 5 to Note T of this unit (*The top floor at a finite place*); Inputs 7 to 9 come from other units and from the background library; Input 10 collects what the local theory needs of standard levels (set-up of this unit) and of the tower method (unit on the real place), facts that Note T recalls and does not prove.

Input 1 (terms and the Bessel subgroup; set-up of this unit). In Setting 2.1, with $\mathcal{U} = \mathcal{U}(T_S^{\mathrm{rat}}(E))$, $\mathcal{S} = \mathcal{S}(T_S^{\mathrm{rat}}(E))$:

(a) *(Size facts.)* $2 \le g(S)$, $2 \le \mathrm{tl}(S)$, $0 \le \mathsf{d}_1(S)$, $0 \le \mathsf{d}(S)$, $0 < \nu(S)$, $0 < \#\overline{\mathcal{S}}^S$; and $\mathrm{tl}(S)^4 = b(S)^{k(\mathfrak{s})f(E)}$.

(b) The set of the rational points of the Bessel subgroup is stable, and so is its complement.

(c) Suppose S is admissible. If $\gamma \in \mathcal{S}$ and $\mathrm{pos}_S(c,d;\gamma) \in K_g(S)$, then $c = d$ and $\gamma \in \mathcal{U}_{S,c}$. If $t \in \overline{\mathcal{S}}^S$ and c is a class, there are a class d and $\gamma \in \mathcal{S}$ with $\gamma \in \mathrm{Tm}_S(c,t,d)$.

(d) *(Freeness.)* Suppose E is stably unramified. Let n be a finite set with $\#n \le k(\mathfrak{s})$, $i \in \{0,1\}$, γ a rational element of the unitary group of the standard form on n and y a finite adelic element of it such that $y^{-1}\gamma y$ is integral and reduces to 1 at every place of $\mathrm{Ch}_i(S)$. Then $\gamma = 1$.

(e) For $\gamma \in G_S(E)$ and classes c, c': the frame vectors satisfy $\mathrm{pos}_S(c,c';\gamma)\,\mathfrak{f}_a = h_S(c)^{-1} \cdot (\gamma \mathfrak{f}_a)$; the frame Gram matrix of $\mathrm{pos}_S(c,c';\gamma)$ for $T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})$ is the image of $Z_S(\gamma)$; and if $\gamma \in \mathcal{U}$, then $\mathrm{pos}_S(c,c;\gamma) \in \mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$.

(f) For an integral finite adele r: $\hat{g}(S)^{-1}r$ is integral exactly if r and $\bar{r}$ vanish modulo every chosen place. For y in the finite adelic unitary group of κ with $\mathrm{inc}_S(y) \in K(S)$: y is integral with integral inverse, and for a chosen place w the reduction of $\mathrm{inc}_S(y)$ at w is 1 exactly if that of y is.

(g) *($\mathcal{U}$ times $\mathcal{H}$.)* Let $u \in \mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and let h be in the image of inc_S. Every entry of h is the corresponding entry of uh or of the identity matrix. If $uh \in K(S)$, then $h \in K(S)$ and $u \in K(S)$; and if moreover the reduction of uh at a chosen place is 1, so is that of h. For a rational element δ of the unitary group of the standard form on κ, read as an element of $\mathcal{H}(T_S^{\mathrm{rat}}(E))$: $\mathrm{r}_S^f(\delta) = \mathrm{inc}_S(\delta)$, so that $\mathrm{pos}_S(c,c;\delta) = \mathrm{inc}_S(y_c^{-1}\delta\, y_c)$ for a class c with representative y_c.

Input 2 (amplitude sums; set-up of this unit). In Setting 2.1, suppose that E is stably unramified and S admissible; let σ be a side and $\Xi, \Xi' \subseteq G_S(E)$.

(a) *(Splitting.)* $A_S^\sigma(\Xi; c, s, c') = A_S^\sigma(\Xi \setminus \Xi'; c, s, c') + A_S^\sigma(\Xi \cap \Xi'; c, s, c')$ for all c, s, c'; the families of amplitudes are summable.

(b) *(The identity term.)* For classes c, c' and $i, j \in \mathrm{Bc}(S)$: $A_S^{\mathrm{full}}(\mathcal{S}(T_S^{\mathrm{rat}}(E)); c, 1, c')_{(i,j)}$ equals $\nu(S)$ if $c = c'$ and $i = j$, and 0 otherwise.

(c) *(Equivariance under $\mathcal{U}$.)* If Ξ is stable and $u, u' \in K(S)$ lie in $\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, then $A_S^\sigma(\Xi; c, \mathrm{red}_S(u)\, s\, \mathrm{red}_S(u')^{-1}, c') = \psi_S^{\mathcal{U}}(u)^{-1}\psi_S^{\mathcal{U}}(u') \cdot A_S^\sigma(\Xi; c, s, c')$.

(d) *(Moves.)* Let Ξ be stable, let $\gamma_0 \in \mathcal{S}(T_S^{\mathrm{rat}}(E)) \cap \mathrm{Tm}_S(c, t, c_1)$ and $\gamma_0' \in \mathcal{S}(T_S^{\mathrm{rat}}(E)) \cap \mathrm{Tm}_S(c', t', c_1')$ be such that $\gamma \in \Xi \iff \gamma_0\gamma\gamma_0'^{-1} \in \Xi$ for all γ, and let L be a continuous linear map of $\ell^2(\mathrm{Bc}(S) \times \mathrm{Bc}(S))$ that takes the tensor $W(y) \otimes \overline{W(\mathrm{r}_S^\infty(\gamma)^{-1}y)}$ of the Bessel functions of the side σ to the same tensor formed for $\gamma_0\gamma\gamma_0'^{-1}$ at the point $\mathrm{r}_S^\infty(\gamma_0)y$, for all γ and y. Then $A_S^\sigma(\Xi; c, t\, s\, t'^{-1}, c') = L\big(A_S^\sigma(\Xi; c_1, s, c_1')\big)$ for all s.

(e) *(The Bessel functions under the Bessel subgroup.)* For rational $u \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$ and $\eta \in \mathcal{H}(T_S^{\mathrm{rat}}(E))$ and every point y,

$$W_S^{\mathrm{full}}(\mathrm{r}_S^\infty(u\eta)\, y)_\cdot = \psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u))^{-1} \cdot A_\eta\, W_S^{\mathrm{full}}(y)_\cdot,$$

where $|\psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u))| = 1$ and A_η is a unitary operator of $\ell^2(\mathrm{Bc}(S))$: the tensor product over τ of the values at the image of η of the unitary representations of the Bessel systems $\mathfrak{B}_\tau(S)$.

Input 3 (the crude estimate; set-up of this unit). In Setting 2.1, suppose that E is stably unramified and S admissible. Let $C \geq 0$ and $\omega_0 \geq 0$ be real numbers, $\Omega \subseteq \mathsf{G}(S)$, $\Xi \subseteq G_S(E)$ a stable set, and $X \neq 0$ a natural number such that every $s \in \Omega$ fixes norm at least X. Suppose that $\mathsf{d}_1(S) \leq C$; that $\mathrm{tl}(S)^{20}\mathsf{d}_1(S) \leq C$ if some $\gamma \in \Xi$ that is a term over some (c, s, c') with $s \in \Omega$ is in normal form of index 0; let $\mathcal{R}$ be a set of links such that $\mathrm{tl}(S)^{12}X^{-k(s)}\mathsf{d}(S) \leq C$ if some link is not in $\mathcal{R}$; and suppose that the link energy of the cut side satisfies

$$\sum_{c,c'} \sum_{s \in \Omega} \sum_{\Lambda \in \mathcal{R}} \big\| A_S^{\mathrm{cut}}(\{\gamma \in \Xi :\ \mathsf{g}_S(\gamma) \neq 0,\ \mathrm{link}(\gamma) = \Lambda\}; c, s, c') \big\|^2 \ \leq\ \omega_0\, \nu(S)^2.$$

Then $\mathrm{En}_S(A_S^{\mathrm{full}}(\Xi; \cdot, \cdot, \cdot); \Omega) \leq (1 + b(S)^{-4})^2\, \omega_0 + b(S)^{-12}\, C$. Here $\mathrm{link}(\gamma)$ is the link of γ, a subspace attached to γ in the set-up; and γ is *in normal form of index* 0 if there is $v \in E$ with $v\bar{v} = 1$ such that for every frame index a there are coefficient vectors x, y, supported on the indices $\leq a$, with $x_a = v$, $y_a = 1$ and $\sum_{a'} x_{a'}\mathsf{f}_{a'} = \gamma \sum_{a'} y_{a'}\mathsf{f}_{a'}$.

Input 4 (levels at finitely many places and the unfolding; Note G). In Setting 2.1:

(a) If E carries Weil data, then for every finite set T of finite places that is stable under complex conjugation, E_{T} carries an integral place structure and a level $\mathcal{L}$ with $\mathcal{L} \in \mathrm{FL}(S, \mathsf{T})$. For every finite set T_0 of units of E there are arbitrarily large such T off which all $t^{\pm 1}$ ($t \in \mathsf{T}_0$), $\hat{g}(S)^{-1}$, $N(S)^{-1}$, $\Lambda(S)$ and $\Lambda(S)^{-1}$ are integral; and every element of G_S^{lat} is integral off all sufficiently large T.

(b) In Setting 2.3: every $y \in G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ is $\mathrm{loc}_{S,\mathsf{T}}(x)$ for some x integral off T, with $x \in \mathcal{U}$ if $y \in \mathcal{U}$ and $x \in \mathcal{H}$ if $y \in \mathcal{H}$; an x lies in $K(S)$ exactly if it is integral off T and $\mathrm{loc}_{S,\mathsf{T}}(x) \in K_{S,\mathsf{T}}(1)$. If moreover $\hat{g}(S)^{-1}$ is integral off T: x lies in $K_g(S)$ exactly if it is integral off T and $\mathrm{loc}_{S,\mathsf{T}}(x) \in K_{S,\mathsf{T}}(g_{\mathcal{L}})$; for $k, l \in K(S)$, $\mathrm{red}_S(k) = \mathrm{red}_S(l) \iff \mathrm{loc}_{S,\mathsf{T}}(k)^{-1}\,\mathrm{loc}_{S,\mathsf{T}}(l) \in K_{S,\mathsf{T}}(g_{\mathcal{L}})$; for x integral off T, $\psi_{\mathsf{T}}(g_{\mathcal{L}}^{-1}\,\mathrm{sd}(\mathrm{loc}_{S,\mathsf{T}}(x))) = \psi_S^{\mathcal{U}}(x)$; $\mathrm{uo}(S) \cdot \mathsf{v}(\mathcal{L}) = 1$; $\mathrm{mod}_{\mathsf{T}}(g_{\mathcal{L}}) = g(S)^{-2f(E)}$; and for a unit x of E with x, x^{-1} integral off T, $\mathrm{mod}_{\mathsf{T}}(x_{\mathsf{T}})^{1/2} = \prod_\tau |x_\tau|^{-1}$.

(c) In Setting 2.3 with $\hat{g}(S)^{-1}$ integral off T: if B is a subgroup of G_S^{lat} and μ an s-finite measure on $G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ such that μ-almost every point is $\mathrm{loc}_{S,\mathsf{T}}(x)$ for some $x \in B$ that is integral off T, and such that μ is invariant under right translation by $\mathrm{loc}_{S,\mathsf{T}}(x)$ for *every* $x \in B$, then $\#\overline{B}^{S} \cdot \mu(K_{S,\mathsf{T}}(g_{\mathcal{L}})) = \mu(K_{S,\mathsf{T}}(1))$. If E carries Weil data, $\#\overline{\mathcal{S}}^{S} = \#\overline{\mathcal{H}}^{S} \cdot \mathrm{uo}(S)$.

(d) *(The floor group.)* For $\gamma \in \mathcal{H}_{\varrho}(T_S^{\mathrm{rat}}(E))$ and classes c, c', put $l = \mathrm{pos}_S(c, c'; \gamma)$, $t = Z_S(\gamma)_{\varrho\varrho}$ and let $\omega \in E^{\kappa}$ be the κ-part of γz. Then $l \in \mathcal{H}_{\varrho}$, $l\,z = \mathrm{tv}(\bar{\pi}(S), t, y_c^{-1}\omega)$ with y_c the representative of c, $N(S)\,\omega^*\omega = t\bar{t} - N(S)^2$, and $\mathrm{pos}_S(c, c'; w_{\varrho}(p)\gamma) = w_{\varrho}(p)\,l$ for every family p of units of E; at an infinite place τ, $\mathrm{r}_S^{\infty}(w_{\varrho}(p)\gamma)_\tau = w_{\varrho}(p^{(\tau)}) \cdot \mathrm{r}_S^{\infty}(\gamma)_\tau$ with $p_a^{(\tau)} = u(\mathrm{fs}_S(\tau, a) \cdot (p_a)_\tau)$. Here $\mathrm{tv}(\pi, t, x)$, for a unit π, an element t and a vector x indexed by κ, is the vector $x - (\pi\bar{\pi})^{-1} t\,z$ written in the lattice basis formed with π. Taking components commutes with it: for T stable under conjugation, a finite adele t and $x \in \mathbb{A}_{E,f}^{\kappa}$, $\mathrm{tv}(\bar{\pi}(S), t, x)_{\mathsf{T}} = \mathrm{tv}(\bar{\pi}(S)_{\mathsf{T}}, t_{\mathsf{T}}, x_{\mathsf{T}})$.

Input 4, continued (Note G). In Setting 2.1:

(e) *(Blocks as limits of coset amplitudes.)* Suppose E carries Weil data and S is admissible; let σ be a side, c, c' classes, $s \in \mathsf{G}(S)$ and Λ a link. If $A^{\sigma}_{S}(\{\gamma : \mathfrak{g}_S(\gamma) \neq 0,\ \mathrm{link}(\gamma) = \Lambda\}; c, s, c') \neq 0$ and all leading minors of $Z_S(\gamma)$ are non-zero for every $\gamma \in \mathrm{Tm}_S(c, s, c')$, then there are a unit t of E, an element $\gamma_1 \in \mathcal{H}_{\varrho}(T^{\mathrm{rat}}_S(E))$ and $k \in K(S)$ with $Z_S(\gamma_1)_{\varrho\varrho} = t$, $N(S)^2 < |t_\tau|^2$ for all τ, $\mathrm{red}_S(k) = s$, $\Lambda = \mathrm{link}(w_{\varrho}(1)\gamma_1)$, and a family (L_p) of vectors, indexed by the maps p from $\{0, \dots, \varrho(\mathfrak{s}) - 1\}$ to $E^{\times}$, which is summable with sum the amplitude sum above, such that for every p, $a^{\sigma}_{S,\mathsf{T}}(c, s, c'; w_{\varrho}((p \,|\, t))\gamma_1) \to L_p$ as T grows.

(f) *(Unfolding.)* In Setting 2.3 with $\hat{g}(S)^{-1}$ integral off T, suppose E carries Weil data and S is admissible; let σ be a side, $\gamma_1 \in \mathcal{H}_{\varrho}(T^{\mathrm{rat}}_S(E))$, p a family of units of E with $\mathrm{pos}_S(c, c'; w_{\varrho}(p)\gamma_1)$ integral off T, $Z \in \mathrm{Int}(\mathcal{L})$, $k \in K(S)$ and cosets $a, b \in \mathrm{Cos}(Z)$ with $\mathrm{loc}_{S,\mathsf{T}}(k)^{-1} a_a a_b^{-1} \in K_{S,\mathsf{T}}(g_{\mathcal{L}})$. Then, with $\gamma = w_{\varrho}(p)\gamma_1$ and $W^{\sigma} = W^{\sigma}_S(\cdot)$,,

$$\begin{aligned}\mathcal{J}(Z; p_{\mathsf{T}}, \mathrm{loc}_{S,\mathsf{T}}(\mathrm{pos}_S(c, c'; \gamma_1))^{-1})_{(a,b)} \cdot \mathrm{J}(dy, W^{\sigma}; \mathrm{r}^{\infty}_S(\gamma)) \\ = \mathsf{h}_{\varrho}(\mathcal{L}; p_{\mathsf{T}}, 1) \cdot \mathsf{M}(\mathcal{L})(K_{S,\mathsf{T}}(g_{\mathcal{L}})) \cdot a^{\sigma}_{S,\mathsf{T}}(c, \mathrm{red}_S(k), c'; \gamma).\end{aligned}$$

Input 5 (the local theory at T; Note T). In Setting 2.3, with $K_g = K_{S,\mathsf{T}}(g_{\mathcal{L}})$, $K_1 = K_{S,\mathsf{T}}(1)$ and $Z \in \mathrm{Int}(\mathcal{L})$:

(a) If $\chi_g(y) \neq 0$ then $u^{-1} y \in K_{S,\mathsf{T}}(g)$ for some $u \in \mathcal{U}$, and then $\chi_g(y) = \psi_{\mathsf{T}}(g^{-1}\,\mathrm{sd}(u))$ for every such u; $\chi_g(yk) = \chi_g(y)$ for $k \in K_{S,\mathsf{T}}(g)$; and $y\, a_c^{-1} \in K_g$ holds for exactly one coset $c \in \mathrm{Cos}(Z)$ when $y \in Z$.

(b) *(The bottom value.)* For every natural number t with $t + 10^{10} n(\mathfrak{s})^4 \leq k(\mathfrak{s})$,

$$\mathcal{I}_0(\mathcal{L}; Z) \ \leq\ \mathsf{M}(\mathcal{L})(Z)\, \mathsf{M}(\mathcal{L})(K_g) \Big(\mathsf{M}(\mathcal{L})(Z) + \mathrm{vol}(O_{\mathsf{T}} \setminus O_{\mathsf{T}}^{\times})^{t+1}\, 2^{-n(\mathfrak{s})} \Big);$$

and $\int_{K_g} \big| \int_Z \chi_{g_{\mathcal{L}}}(yxy^{-1}) d\mathsf{M}(\mathcal{L})(y) \big|^2 d\mathsf{M}(\mathcal{L})(x) = \mathsf{M}(\mathcal{L})(Z)^2 \mathsf{M}(\mathcal{L})(K_g)$.

(c) If $B \geq 2$ and $\mathrm{vol}(O_{\mathsf{T}} \setminus O_{\mathsf{T}}^{\times}) \leq B^{-1}$, then $2^{-n(\mathfrak{s})} \leq \mathsf{M}(\mathcal{L})(K_1)$. Always $0 < \mathrm{mr}(Z) < \infty$.

(d) *(Frequency bound.)* Let $j \leq \varrho(\mathfrak{s})$, K and t natural numbers with $10^{10} n(\mathfrak{s})^4 \leq K$ and $t + 10^{10} n(\mathfrak{s})^4 \leq k(\mathfrak{s})$, ξ a unit of E_{T}, p, q sequences of units, and ω a function such that either $\omega(x) = \psi_{\mathsf{T}}(\xi \cdot Z(x)_{jj})$, or $j = i + 1$, $\omega = 1$ and $\xi = g_{\mathcal{L}}^{-1}(p_i^{-1} - q_i^{-1})$ for some i. Then

$$\begin{aligned}&\big| \mathcal{J}_j(\mathcal{L}; p, q; W_Z(\cdot), \omega) \big| \\ &\qquad \leq\ \mathrm{mr}(Z) \cdot [\xi]^{t/2}\, \mathrm{den}(\xi)^{-6} \Big(\frac{2}{\mathrm{mod}_{\mathsf{T}}(g_{\mathcal{L}})} \Big)^{K} \Lambda_K(j; p)\, \Lambda_K(j; q).\end{aligned}$$

Input 5, continued (Note T). In Setting 2.3, with K_g, K_1 and $Z \in \mathrm{Int}(\mathcal{L})$ as before:

(e) *(The top floor.)* For every $\xi \in E_{\mathsf{T}}$ and sequences p, q, the function $l \mapsto \psi_{\mathsf{T}}(\xi\, h(z, l^{-1}z))\langle \mathcal{J}(Z;p,l), \mathcal{J}(Z;q,l)\rangle$ is integrable for $\mu^{\mathcal{L}}_{\varrho,2}$, with integral $\mathcal{I}_{\varrho}(\mathcal{L};p,q;W_Z(\cdot),\omega_\xi)$, $\omega_\xi(x) = \psi_{\mathsf{T}}(\xi\, h(z,xz))$. For an open additive subgroup L, $(p,q) \mapsto \mathcal{K}(L;Z;p,q)$ is continuous.

(f) *(Energy and the top kernel.)* Let L be open, R a positive semidefinite matrix and ω a family of sequences of units, indexed by the same finite set, with $(\omega_p)_{\varrho} = t$ for all p. Then $\mathcal{Q} = \sum_{p,q} R_{pq}\, \mathcal{K}(L;Z;\omega_p,\omega_q)$ is real and ≥ 0, and

$$\int \mathbf{1}\big[(Je)_z - t \in L\big]\ \mathcal{E}(Z;R,\omega,e)\ d\delta^{(\varrho)}(\mathcal{L})(e)\ \leq\ \mathcal{Q},$$

J the split Gram matrix of $T^{\mathrm{lat}}_S(E_{\mathsf{T}})$.

(g) *(Packets.)* Let e be a vector and $(l_\theta, n_\theta)_{\theta\in\Theta_0}$ a non-empty finite family with $l_\theta \in \mathcal{H}_\varrho$, $l_\theta^{-1}z = e$ and $n_\theta \in \mathrm{Cos}(Z) \times \mathrm{Cos}(Z)$, such that $l_\theta l_{\theta'}^{-1} \in K_g$ and $n_\theta = n_{\theta'}$ imply $\theta = \theta'$; let R be a complex matrix and ω a family of sequences of units, indexed by the same finite set. Then for all x in a neighbourhood of e, all $k \in \mathcal{H} \cap K_g$ and all y with $ky = x$,

$$\theta_n(\mathcal{L})(K_g) \cdot \sum_\theta \big(\mathrm{Re}\ v_\theta^* R v_\theta\big)^+\ \leq\ \mathcal{E}(Z;R,\omega,y), \qquad v_\theta(p) = \mathcal{J}(Z;\omega_p,l_\theta)_{n_\theta}.$$

(Note T assumes here that the units of the ring form an open set and that inversion is continuous at 1; both hold in E_{T}, a finite product of local fields.)

(h) *(What the tower method needs of the finite Bessel vector.)* The function $W = W_Z(\cdot)$ is a cut Bessel function for $\mathcal{L}$ in the sense of the unit on the real place: it is measurable and bounded, $W(uy) = \psi_{\mathsf{T}}(g_{\mathcal{L}}^{-1}\,\mathrm{sd}(u))\, W(y)$ for $u \in \mathcal{U}$, and $W(y) \neq 0$ only if $uy \in K_1$ for some $u \in \mathcal{U}$ (Note T, Lemma 4.5). For $j \leq \varrho(\mathfrak{s})$ and sequences p, q of units, the majorant of the floor form $\mathcal{J}_j(\mathcal{L};p,q;W,\cdot)$, a function on $G(T^{\mathrm{lat}}_S(E_{\mathsf{T}}))$ with values in $[0,\infty]$ that the unit on the real place defines, has a finite integral for $\mathsf{M}(\mathcal{L})$ (Note T, Corollary 5.5 for the number 0, which is admissible because $10^8 n(\mathfrak{s})^4 \leq k(\mathfrak{s})$). And for every x,

$$\Big|\int_Z \chi_{g_{\mathcal{L}}}(yxy^{-1})\, d\mathsf{M}(\mathcal{L})(y)\Big| = \mathsf{v}(\mathcal{L}) \cdot \big|\mathsf{A}(\mathcal{L};W,x)\big|$$

(Note T, Lemma 4.8), with the average $\mathsf{A}(\mathcal{L};W,x)$ of Input 10(d).

Input 6 (the sieve, and slabs near a quadric; set-up of this unit). (a) In Setting 2.1, suppose E carries Weil data and S is admissible. Let T be a finite set of finite places, stable under complex conjugation, with $\hat{g}(S)^{-1}$ integral off T; let T_0 be a finite set of units of E with t, t^{-1} integral off T for $t \in \mathsf{T}_0$, and $U \subseteq \mathsf{T}_0$. Let J' and $\mathcal{E}_0$ be such that the maps $c \mapsto u(c)$, $x \mapsto g(S)_{\mathsf{T}}^{-1} x^{-1}$, the depth $\varrho(\mathfrak{s})$, J', the character $\psi_{S,\mathsf{T}}$, the number $\mathcal{E}_0$, the weights $\Lambda_{n(\mathfrak{s})^6}(\cdot;\cdot)$ and the frequency gain $\beta_{S,\mathsf{T}}(\cdot)$ form a sieve system on E_{T}. Then

$$\begin{aligned} &\operatorname{Re} \sum_{t \in U} \sum_{p,q} \Big(\prod_{\tau} \mathrm{bl}_\tau(x_\tau(p,t), x_\tau(q,t)) \Big) J'\big(n(\mathfrak{s}), (p \,|\, t)_{\mathsf{T}}, (q \,|\, t)_{\mathsf{T}}\big) \\ &\leq \prod_{a < n(\mathfrak{s})} \frac{\mathrm{vol}(\hat{O}_E)}{\prod_\tau \mathrm{fs}_S(\tau, a)^2} \cdot \Big(\prod_\tau \frac{1 + b(S)^{-10}}{\deg \mathfrak{B}_\tau(S)} \cdot \mathcal{E}_0 + \frac{\deg(S)^{-1}}{b(S)^{\,6k(\mathfrak{s})f(E)+10}} \Big), \end{aligned}$$

where p, q run over the maps from $\{0, \dots, \varrho(\mathfrak{s}) - 1\}$ to T_0, bl_τ is the band limit of the Bessel system $\mathfrak{B}_\tau(S)$ at level $n(\mathfrak{s})$, and $x_\tau(p,t)$ is the sequence $a \mapsto u\big(\mathrm{fs}_S(\tau, a) \cdot ((p \,|\, t)_a)_\tau\big)$. The band limit of a Bessel system with index set I_τ and cut Bessel function W_τ^{cut} satisfies: for $\gamma \in \mathcal{H}_\varrho$ in the real group $G_1(\mathfrak{s})$ and sequences p, q of non-zero complex numbers with $p_\varrho = q_\varrho = Z(\gamma)_{\varrho\varrho}$, $\mathrm{bl}_\tau(p,q) = \langle \mathrm{nc}_\tau(\gamma, p), \mathrm{nc}_\tau(\gamma, q) \rangle$, where

$$\begin{aligned} \mathrm{nc}_\tau(\gamma, p) = \frac{\sqrt{\mathrm{oc}(\mathfrak{s})}\,(|p_\varrho|^2 - 1)^{(k(\mathfrak{s})-1)/2}}{\#I_\tau} \prod_{a < \varrho(\mathfrak{s})} |p_a|^{k(\mathfrak{s})+1+2(\varrho(\mathfrak{s})-a-1)} \\ \cdot \mathrm{J}(dy, W_\tau^{\mathrm{cut}}; w_\varrho(p)\gamma). \end{aligned}$$

Input 6, continued (slabs near a quadric; set-up of this unit). (b) Let A be a semilocal field with involution and an integral place structure, π a unit with $\pi\bar{\pi} = N$, $\mathcal{B}$ a hyperbolic basis of the lattice form of the shape $\mathfrak{s}$ for N, with its quadric measure $\delta^{(\varrho)}(\mathcal{B})$, $\Phi \geq 0$ a continuous function with compact support on $A^{I(\mathfrak{s})}$ and $c > \int \Phi \, d\delta^{(\varrho)}(\mathcal{B})$. Then for all sufficiently small measurable sets $M \subseteq A$,

$$\begin{aligned} \int \int_{\{y:\ y^* y - ((\pi\bar{\pi})^{-1}\tau\bar{\tau} - N) \in M\}} \Phi\big(\mathrm{tv}(\pi, \tau, y)\big)\, dy\, d\tau \\ \leq\ \mathrm{mod}_A(\pi) \cdot \nu_A(\delta_A M) \cdot c, \end{aligned}$$

with ν_A the measure on the skew elements and δ_A the skew unit of the place structure. Further, for a unit π with $\pi\bar{\pi} = N$ and $e = \mathrm{tv}(\pi, t, x)$: $(Je)_z = t$ for the split Gram matrix J of the lattice form.

Input 7 (positive type and variance; unit on heights). Let G be a finite group, H a complex inner product space.

(a) If $u, v\colon G \to H$ satisfy $\langle u(a), v(b)\rangle = f(a^{-1}b)$, then $\langle \sum_a u(a), \sum_a v(a)\rangle = \#G \cdot \sum_s f(s)$.

(b) Let k be a finite field, n, m finite sets, $\pi\colon G \to \mathrm{GL}_n(k)$ a homomorphism, A_0, A_1 matrices over k with rows indexed by n and columns by m, $\Theta\colon G \to \mathbb{R}$ with $\Theta \geq 0$ and $\langle u(a), u(b)\rangle = \Theta(a^{-1}b)$ for a family $u\colon G \to H$, and $Y \geq 0$ such that for every $v \neq 0$ in k^m the sum of Θ over the s with $\pi(s)A_0 v = A_0 v$, and the sum over the s with $(\pi(s)^{-1})^t A_1 v = A_1 v$, are at most Y. Then

$$\#k \cdot \sum_{s\colon \det(A_1^t \pi(s) A_0)=0} \Theta(s) \;\leq\; 2\sum_s \Theta(s) + \#k^{\#m}\sqrt{\#k^{\#n}} \cdot Y.$$

(c) For an orthonormal basis $\mathbf{b}$ of H (finite-dimensional) and a finite family $v = (v_x)$ in H, let $\mathrm{dy}_{\mathbf{b}}(v) = \sum_x \bar{v}_x \otimes v_x$, the conjugates taken in the coordinates of $\mathbf{b}$; then $\langle \mathrm{dy}_{\mathbf{b}}(v), \mathrm{dy}_{\mathbf{b}}(v')\rangle = \sum_{x,y} |\langle v'_y, v_x\rangle|^2$. Let $\mathsf{P}\colon \mathbb{C}^n \to H$ and $\mathsf{R}\colon H \to H$ be linear, U a subspace of $\mathbb{C}^n$ and A one of H, with $\mathsf{P}v - \mathsf{RP}v \in A$ for $v \in U$, and $\sum_x \|(\mathsf{P}^*\mathsf{P} - 1)e_x\| \leq \varepsilon$. Then

$$\dim U - \varepsilon - \sum_x \|\mathsf{RP}e_x\|^2 \;\leq\; \mathrm{Re}\langle \mathrm{dy}_{\mathbf{b}}((\mathsf{P}e_x)_x), \mathrm{dy}_{\mathbf{b}}(\mathbf{a})\rangle$$

for an orthonormal basis $\mathbf{a}$ of A that the library chooses.

Input 8 (background library).

(a) *(Central idempotents.)* If x_i are central idempotents of the group algebras of finite groups G_i, so are $1 - x_i$ and the tensor $\otimes_i x_i \in \mathbb{C}[\prod_i G_i]$. For a central idempotent x and a unitary representation, the operator of x is self-adjoint. If x is a central idempotent of $\mathbb{C}[G]$, then $\#G \cdot x(\cdot)$ is the character of a representation of G; in particular $x(s^{-1}) = \overline{x(s)}$ and $\sum_s |x(s)|^2 = (x \cdot x)(1) = x(1)$. For a homomorphism $\varphi\colon G \to G'$ of finite groups, a central idempotent x of $\mathbb{C}[G]$ and a family f of vectors indexed by G': $\sum_s \| \sum_t x(t) f(\varphi(t)^{-1} s) \|^2 \le \sum_s \|f(s)\|^2$. Elementary; reference to be confirmed.

(b) *(Siegel's formula for one vector.)* Let E carry Weil data, κ be a finite set with $\#\kappa \ge 3$, K an open compact subgroup of the finite adelic unitary group of the standard form on κ, Φ_0 a locally constant function with compact support on $\mathbb{A}_{E,f}^{\kappa}$, invariant under K, with values ≥ 0, and $\alpha \in E$ with $\bar{\alpha} = \alpha$ and $\operatorname{Re} \alpha_\tau > 0$ for all τ. Then, with the sum over the classes h of K, weighted by the inverses of the orders of their automorphism groups,

$$\sum_h \sum_{x \in E^\kappa,\ x^* x = \alpha} \Phi_0(h^{-1} x) = \Big(\sum_h 1 \Big) \cdot |d_E|^{1/4} \prod_\tau \frac{\pi^{\#\kappa}}{(\#\kappa - 1)!} (\operatorname{Re} \alpha_\tau)^{\#\kappa - 1} \cdot \int \int \psi_f(\tfrac{1}{2} z (x^* x - \alpha)) \Phi_0(x) \, dx \, dz,$$

z over the self-adjoint finite adeles. This is a special case of Weil's mean-value identity on a non-zero index fibre (A. Weil, *Sur la formule de Siegel dans la théorie des groupes classiques*, §52, Theorem 5, equation (41)), with the constants of one vector worked out in the formal text; the comparison is the second reader's.

Input 8, continued (background library).

(c) *(Local densities off* T*.)* Let E carry Weil data and κ be a finite set. Let $M \geq 1$ be an integer, $m \in \mathbb{A}_{E,f}$ with $Mm = 1$, and $\mathfrak{c}_M$ the *codifferent scaled by* M: the group of the self-adjoint finite adeles z with Mz in the inverse different of E, a compact open subgroup of the self-adjoint finite adeles. Let $\beta \in \mathbb{A}_{E,f}$ with $\bar{\beta} = \beta$, let T be stable under conjugation with an integral place structure on E_{T}, and let a_0 be a natural number with $\zeta_{\hat{O}_E}(a_0) \leq 2$ and $2(a_0+1) \leq \#\kappa$, where $\zeta_{\hat{O}_E}$ is the ideal zeta function of $\hat{O}_E$.
(i) For every finite measure μ on $\mathbb{A}_{E,f}^{\kappa}$,

$$\Big| \int_{\mathfrak{c}_M} \int \psi_f(\tfrac{1}{2} z(x^*x - \beta))\, d\mu(x)\, dz \Big| = \mathrm{vol}(\mathfrak{c}_M) \cdot \mu\{x : \ m(x^*x - \beta) \in \hat{O}_E\}.$$

(ii) There is a finite number $v_0 \geq 0$ with

$$\mathrm{vol}(\mathfrak{c}_M) \cdot \nu_{\mathsf{T}}\{\Gamma : \ m_{\mathsf{T}} \delta_{\mathsf{T}}^{-1} \Gamma \in O_{\mathsf{T}}\} \cdot v_0 \ \leq \ \zeta_{\hat{O}_E}(a_0) \cdot \mathrm{vol}(\hat{O}_E)^{\#\kappa}$$

such that for all $a \in E_{\mathsf{T}}$, with extension by zero $\tilde{a}$, and all measurable $f \geq 0$ on E_{T}^{κ},

$$\int_{\{x:\ m(x^*x - \beta - \tilde{a}) \in \hat{O}_E\}} \mathbf{1}[x \text{ integral off } \mathsf{T}]\, f(x_{\mathsf{T}})\, dx$$
$$= v_0 \int_{\{y:\ m_{\mathsf{T}}(y^*y - \beta_{\mathsf{T}} - a) \in O_{\mathsf{T}}\}} f(y)\, dy.$$

Here ν_{T} is the measure on the skew elements and δ_{T} the skew unit of the place structure.
(iii) $\zeta_{\hat{O}_E}(u+v+4)^{n'} \leq 1 + 2^{-u}$ for natural numbers u, v, n' with $n'[E:\mathbb{Q}] \leq 2^v$; and for a unit u of a semilocal field A with an integral place structure, $\mathrm{vol}\{x : ux \in O_A\} = \mathrm{mod}_A(u)^{-1}$. Reference to be confirmed.

Input 8, continued (background library).

(d) *(Haar measure.)* On a locally compact second countable group with a right-invariant Haar measure μ, every s-finite right-invariant measure is $d \cdot \mu$ for some $d \in [0, \infty]$. The regular case is classical (compare F. van Doorn, *Formalized Haar measure*, §6, Theorem 12); the relation of the s-finite form with an infinite multiplier to the literature is recorded as unresolved by the second reader.

(e) *(Finite groups.)* The stabiliser of a non-zero vector of k^n in $\mathrm{GL}_n(k)$, k a finite field, has index $\#k^{\#n} - 1$. Elementary.

(f) *(Forms, classes, mass.)* For a level K with trivial class automorphism groups, the space of forms of level K of an algebraic type has dimension the number of classes times the dimension of the weight representation; the number of classes of $K' \leq K$ is the index times that of K when counted with weights; the weighted number of classes of the maximal level of rank r is $\mathrm{mass}(E, r)$; right translation is unitary for the Petersson product; a level has positive finite volume. Reference to be confirmed.

(g) *(Formal degree.)* For a Harish-Chandra parameter with a large gap, the formal degree of the discrete series is given by Weyl's dimension polynomial (Harish-Chandra, *Discrete series for semisimple Lie groups II*, Acta Math. 116 (1966), §41, Theorem 16; the exact comparison of measures and coefficients with the formal statement is recorded as open by the second reader).

(h) *(Place structures.)* In a semilocal field A with a place structure almost every element, for the Haar measure, is a unit, and $\mathrm{mod}_A(\bar{x}) = \mathrm{mod}_A(x)$. Both are among the conditions that the library puts on a place structure; they hold for a finite product of local fields.

Input 9 (the data). In Setting 2.5:

(a) *(Note G.)* $S(D)$ is admissible, $E(D)$ carries Weil data, $b(S(D)) = b(D)$, $N(S(D)) = N(D)$, $r(\mathfrak{s}) = r(D)$ for the shape of $S(D)$, and $\deg(S(D))$ is the product over the infinite places of the degrees of Bessel systems that fit the type of the rows.

(b) *(Petersson unfolding; set-up of this unit and unit on the seesaw.)* For $s \in \mathsf{G}(D)$ and $a = (c, i)$, $a' = (c', i')$ in $\mathrm{Cl}(S(D)) \times \mathrm{Bc}(S(D))$,

$$\begin{aligned}&\langle \mathrm{rep}_{D, Y_0(D)}(s)\, \mathcal{P}^{\mathrm{fit}}_{S(D)}(e_{a'}),\ \mathcal{P}^{\mathrm{fit}}_{S(D)}(e_a)\rangle \\ &\qquad = \mathrm{vol}(K_g) \cdot A^{\mathrm{full}}_{S(D)}(G_{S(D)}(E(D)); c, s, c')_{(i,i')},\end{aligned}$$

with $\mathrm{vol}(K_g) > 0$ the volume of the principal level at the chosen primes.

(c) *(Good idempotent; units on labels and good forms.)* $e_0(D) = g_0 \otimes g_1$, where g_i is the sum of the label idempotents over the good tuples at the chosen primes above $g_i(D)$; each g_i is a central idempotent, and $\mathrm{Re}\,(1 - g_i)(1) \le b(D)^{-8}/2$. (The first is a restricted form of Green's classification, J. A. Green, *The characters of the finite general linear groups*, Trans. Amer. Math. Soc. 80 (1955), §8, Theorems 13–14, in the second reader's comparison; the second is the bound for the bad share of the note *Primitive labels*, with the sizes of the data.)

(d) *(Ramified columns; unit on the columns.)* For $\mathcal{W} \subseteq \mathrm{Div}_N(D)$ and a subspace X of $\mathrm{Col}(D)$: $\dim \mathrm{Ram}_D(\mathcal{W})^{-1}(X) \le \dim X + \#\mathcal{W}\,(N(D) - 1)^{-1} \dim \mathrm{Col}(D)$. Moreover $\#\mathrm{Div}_N(D) = f(E(D))$.

(e) *(Sizes; Chapter III.)* $b(D)^9 \le N(D) - 1$; $b(D)^{-2} < 1/2$; and $\frac{19}{2}\, b(D)^{-4} + f(E(D))\,(N(D) - 1)^{-1} \le b(D)^{-2}$, a comparison of the logarithmic sizes of the data.

(f) *(Rows; note Good forms and rows, units on the rows and on the exchange.)* $\dim \mathrm{Row}(D)$ equals the dimension of the good forms on the space $W_{m(D)}(D)$, which is standard, hence definite; the row parameter $\varkappa_D(\tau, \cdot)$ is strictly decreasing, num_D is a bijection from the row index set $I(D)$ to $\{0, \dots, r(D) - 1\}$, and the doubled row parameters have the gap $h(D)$; a parameter with a gap is a Harish-Chandra parameter, through which the forms of the type of the data on a standard space are algebraic forms; the class automorphism groups of the principal level $K_g(D)$ at the chosen primes are trivial; and its index in the maximal level K_0 is $\#\mathsf{G}(D)$.

Input 10 (standard levels and the tower method). In Setting 2.3; a filling level is a standard level in the sense of the note *Poincaré series of cut Bessel functions* of this unit. Write $K_1 = K_{S,\mathsf{T}}(1)$.

(a) *(Standard levels; note Poincaré series of cut Bessel functions, set-up of this unit.)* $\mathsf{M}(\mathcal{L})$ is a Haar measure of $G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$, invariant under left and right translations (its corollary on the group measure); $\mathsf{M}(\mathcal{L})(K_1) \le 1 + 2^{-n(\mathfrak{s})}$ (its proposition on the mass of the integral group, from above); $\theta_n(\mathcal{L})(K_1) = 1$ (condition (LL2) of a lattice level); and $\mathcal{L}$ has a gauge in the sense of the unit on the real place (the gauge of depth 1 of a standard level).

(b) *(Levels; unit on the real place, note The tower method at a place.)* The measure $\theta_n(\mathcal{L})$ is carried by $\mathcal{H}$, and it is invariant under right translation by every element of $\mathcal{H}$. Both are conditions in the definition of a level.

(c) *(Descent; unit on the real place, note The local theorem for floor forms, Theorem B.)* Let W be a cut Bessel function for $\mathcal{L}$, $j < \varrho(\mathfrak{s})$, $\xi \in E_{\mathsf{T}}$ and p, q sequences of units such that the majorant of the floor form $\mathcal{J}_j(\mathcal{L}; p, q; W, \cdot)$ has a finite integral for $\mathsf{M}(\mathcal{L})$. Then the function $c \mapsto \psi_{\mathsf{T}}(\xi c)\, \mathcal{J}_{j+1}(\mathcal{L}; p[j \mapsto u(c)], q[j \mapsto u(c)]; W, 1)$ on E_{T} is integrable, with integral $\mathcal{J}_j(\mathcal{L}; p, q; W, \omega_\xi)$, $\omega_\xi(x) = \psi_{\mathsf{T}}(\xi\, Z(x)_{jj})$; here $u(c) = c$ if c is a unit and $u(c) = 1$ otherwise, and $p[j \mapsto u]$ is the sequence p with its entry j replaced by u.

(d) *(The floor 0; unit on the real place, the same note.)* Let W be a cut Bessel function for $\mathcal{L}$ and p, q sequences of units. For a point x put

$$\mathsf{A}(\mathcal{L}; W, x) = \int \big\langle W(\sigma), W(\sigma x) \big\rangle \, d\mathsf{M}_{\ge 0}(\mathcal{L})(\sigma),$$

where $\mathsf{M}_{\ge 0}(\mathcal{L})$ is the convolution of all the floor measures of $\mathcal{L}$, from the measure $\theta_n(\mathcal{L})$ down to that of the floor 0. The unit on the real place bounds every floor form by its head density times the integral for $\mathsf{M}(\mathcal{L})$ of its modulus (lemma on form, modulus and majorant). At the floor 0 the head density $\mathsf{h}_0(\mathcal{L}; p, q)$ is an empty product, equal to 1, and the modulus of $\mathcal{J}_0(\mathcal{L}; p, q; W, 1)$ at x is $|\mathsf{A}(\mathcal{L}; W, x)|^2$, by its definition, in which no floor lies below the floor 0, and by the lemma on the integrand at weight 1. Hence

$$\big|\mathcal{J}_0(\mathcal{L}; p, q; W, 1)\big| \;\le\; \int \big|\mathsf{A}(\mathcal{L}; W, x)\big|^2 \, d\mathsf{M}(\mathcal{L})(x).$$

This last inequality is not a formal statement of its own: the formal proof of Proposition 4.7 assembles it from the three facts just named.

4 At finitely many places: fixed lines, Siegel's formula, the finite system

Throughout this section $K_1 = K_{S,\mathsf{T}}(1)$ and $K_g = K_{S,\mathsf{T}}(g_{\mathcal{L}})$ in Setting 2.3.

Intermediate groups that fix lines.

Lemma 4.1 (non-units are rare)**.** *In Setting 2.1, let T be a finite set of finite places of E, stable under complex conjugation, and let E_{T} carry an integral place structure. Suppose that every place of T is a chosen place of S, in $\mathrm{Ch}_0(S) \cup \mathrm{Ch}_1(S)$, or the conjugate of one. Then $2 \le b(S)^9$ and*

$$\mathrm{vol}(O_{\mathsf{T}} \setminus O_{\mathsf{T}}^{\times}) \;\le\; b(S)^{-9}.$$

Proof. The first assertion holds because $b(S) \ge 1000$. Almost every element of E_{T} is a unit of E_{T} (Input 8(h)). Such an element of O_{T} that is not a unit of O_{T} has a component, at some $w \in \mathsf{T}$, of absolute value less than 1; so it lies in $\{x : \varpi_w^{-1} x \in O_{\mathsf{T}}\}$, where ϖ_w is the unit of E_{T} that is a uniformiser at w and 1 elsewhere. This set has volume $\mathrm{mod}_{\mathsf{T}}(\varpi_w^{-1})^{-1} = \#\mathbb{F}_w^{-1}$ (Input 8(c)), and $\#\mathbb{F}_w = q_i(S) \ge b(S)^{10}$ for the index i of the chosen place that is w or $\bar{w}$. As $\#\mathsf{T} \le 2\,(\#\mathrm{Ch}_0(S) + \#\mathrm{Ch}_1(S)) = 4f(E)$ and $4f(E) \le b(S)$,

$$\mathrm{vol}(O_{\mathsf{T}} \setminus O_{\mathsf{T}}^{\times}) \le 4f(E)\, b(S)^{-10} \le b(S)^{-9}. \qquad \square$$

LEAN `Filling.volume_nonunits_le`

Lemma 4.2 (one prime)**.** *In Setting 2.3, suppose that S is admissible. Let $\Sigma \subseteq \mathrm{Ch}_0(S)$, let o be either the word* none *or a place $w_o \in \Sigma$, let $\mathbf{d}$ be frame-vector data for S, and T_0 a finite set of finite places of E such that $\hat{g}(S)^{-1}$ is integral off T_0. Suppose that, if o is a place w_o, then T consists of the places $j \in \mathsf{T}_0$ with $j = w_o$ or $\bar{j} = w_o$. Then there is $Z \in \mathrm{Int}(\mathcal{L})$ such that*

(i) $\mathrm{loc}_{S,\mathsf{T}}(k) \in Z$ *for every $k \in K(S)$ with $\mathrm{red}_S(k) \in \mathrm{Fix}_S(\Sigma, \mathbf{d})$, and*

(ii) $\mathcal{J}_0(\mathcal{L}; Z) \cdot \mathsf{M}(\mathcal{L})(K_1) \cdot c_o \le \mathcal{J}_0(\mathcal{L}; K_1) \cdot \mathsf{M}(\mathcal{L})(Z)$, *where $c_o = 1$ if o is* none *and $c_o = b(S)^{6k(\mathfrak{s})}$ if o is a place.*

Proof. Let $\mathsf{p} \colon K(S) \to G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ be the restriction of $\mathrm{loc}_{S,\mathsf{T}}$. Its image is K_1 (Input 4(b)). If o is *none*, take $Z = K_1$: then (i) holds for every $k \in K(S)$ and (ii) is an equality.

Let o be a place $w = w_o \in \Sigma$, and write $b = b(S)$, $k = k(\mathfrak{s})$, $n = n(\mathfrak{s})$, $\varrho = \varrho(\mathfrak{s})$. By the hypothesis every place of T is w or $\bar{w}$, so Lemma 4.1 gives $2 \le b^9$ and $\mathrm{vol}(O_{\mathsf{T}} \setminus O_{\mathsf{T}}^{\times}) \le b^{-9}$. Let

$$H = \mathrm{red}_S^{-1}(\mathrm{Fix}_{S,w}(\mathbf{d}_w)) \subseteq K(S), \qquad Z = \mathsf{p}(H).$$

Z is an intermediate group. We show $\mathsf{p}^{-1}(K_g) \subseteq H$. Let $x \in K(S)$ with $\mathsf{p}(x) \in K_g$, so that the entries of $g_{\mathcal{L}}^{-1}(\mathsf{p}(x) - 1)$ are integral, where $g_{\mathcal{L}} = \hat{g}(S)_{\mathsf{T}}$. The place w lies in T: otherwise $w \notin \mathsf{T}_0$, and $\hat{g}(S)^{-1}$ would be integral at w, which is false because w lies above $q_0(S)$ (formally, by Input 1(f) for the idempotent of w). Hence the entries of $\hat{g}(S)^{-1}(x - 1)$ are integral at w, so by Input 1(f) the entries of $x - 1$ vanish modulo w: the component at w of $\mathrm{red}_S(x)$ is 1, which fixes every vector, and $x \in H$. Therefore $K_g = \mathsf{p}(\mathsf{p}^{-1}(K_g)) \subseteq Z \subseteq K_1$, using $K_g \subseteq K_1 = \mathsf{p}(K(S))$.

(i). If $\mathrm{red}_S(x) \in \mathrm{Fix}_S(\Sigma, \mathbf{d})$ then, as $w \in \Sigma$, $\mathrm{red}_S(x) \in \mathrm{Fix}_{S,w}(\mathbf{d}_w)$, so $x \in H$ and $\mathsf{p}(x) \in Z$.

The index of Z. Since $\ker \mathsf{p} \subseteq \mathsf{p}^{-1}(K_g) \subseteq H$, we have $\mathsf{p}^{-1}(Z) = H$ and $[K_1 : Z] = [K(S) : H]$. As red_S is surjective (admissibility), this is the index of $\mathrm{Fix}_{S,w}(\mathbf{d}_w)$ in $\mathsf{G}(S)$; and since $s \mapsto s_w^{(\epsilon_w)}$ maps $\mathsf{G}(S)$ onto $\mathrm{GL}_{I(\mathfrak{s})}(\mathbb{F}_w)$, it is the index of the stabiliser of the non-zero vector $\sum_a (v_w)_a \mathsf{f}_a$ in that group, which is $\#\mathbb{F}_w^{2\varrho+k+1} - 1 = q_0(S)^{2\varrho+k+1} - 1$ (Input 8(e)). Put $t = k - 10^{10} n^4$. Then $t + 1 < 2\varrho + k + 1$, hence $q_0(S)^{t+1} \le q_0(S)^{2\varrho+k+1} - 1$; with $b^9 \le b^{10} \le q_0(S)$ and $\mathsf{M}(\mathcal{L})(K_1) = [K_1 : Z]\, \mathsf{M}(\mathcal{L})(Z)$ (the measure is a Haar measure, Input 10(a), and Z is open in the compact group K_1),

$$\mathsf{M}(\mathcal{L})(Z) \cdot b^{9(t+1)} \;\le\; \mathsf{M}(\mathcal{L})(K_1). \tag{1}$$

(ii). From $10^{10} n^4 \le n^6$ and $3n^6 + 12 \le n^7 \le k$ we get $3 \cdot 10^{10} n^4 \le k$, that is $6k \le 9t$, so $b^{6k} \le b^{9t}$. The bottom value (Input 5(b), with this t), the bound for the non-units and $2^{-n} \le \mathsf{M}(\mathcal{L})(K_1)$ (Input 5(c) with $B = b^9$) give

$$\mathcal{J}_0(\mathcal{L}; Z) \;\le\; \mathsf{M}(\mathcal{L})(Z)\, \mathsf{M}(\mathcal{L})(K_g)\, \big(\mathsf{M}(\mathcal{L})(Z) + b^{-9(t+1)} \mathsf{M}(\mathcal{L})(K_1)\big).$$

By (1) and $2 \le b^9$, $2\,(\mathsf{M}(\mathcal{L})(Z) + b^{-9(t+1)}\mathsf{M}(\mathcal{L})(K_1))\, b^{9t} \le \mathsf{M}(\mathcal{L})(Z)\, b^{9(t+1)} + \mathsf{M}(\mathcal{L})(K_1) \le 2\, \mathsf{M}(\mathcal{L})(K_1)$. Hence

$$\mathcal{J}_0(\mathcal{L}; Z) \cdot \mathsf{M}(\mathcal{L})(K_1) \cdot b^{6k} \;\le\; \mathsf{M}(\mathcal{L})(Z)\, \mathsf{M}(\mathcal{L})(K_g)\, \mathsf{M}(\mathcal{L})(K_1)^2.$$

On the other side, restricting the outer integral of $\mathcal{J}_0(\mathcal{L}; K_1)$ to K_g and using the second statement of Input 5(b) for the intermediate group K_1, we get $\mathcal{J}_0(\mathcal{L}; K_1) \ge \mathsf{M}(\mathcal{L})(K_1)^2\, \mathsf{M}(\mathcal{L})(K_g)$. Multiplying by $\mathsf{M}(\mathcal{L})(Z)$ gives (ii). □

LEAN `Filling.IsFillingLevel.exists_intermediateGroup_one_prime`

Proposition 4.3 (lines at several primes)**.** *In Setting 2.3, suppose that S is admissible, that E carries Weil data and that $\hat{g}(S)^{-1}$ is integral off T. Let $\Sigma \subseteq \mathrm{Ch}_0(S)$ and let $\mathbf{d}$ be frame-vector data for S. Then there is $Z \in \mathrm{Int}(\mathcal{L})$ such that*

(i) $\mathrm{loc}_{S,\mathsf{T}}(k) \in Z$ *for every* $k \in K(S)$ *with* $\mathrm{red}_S(k) \in \mathrm{Fix}_S(\Sigma, \mathbf{d})$, *and*
(ii) $\mathcal{J}_0(\mathcal{L}; Z) \cdot \mathsf{M}(\mathcal{L})(K_1) \cdot b(S)^{6k(\mathfrak{s}) \cdot \#\Sigma} \le \mathcal{J}_0(\mathcal{L}; K_1) \cdot \mathsf{M}(\mathcal{L})(Z)$.

Proof. A place of E equals, or is conjugate to, at most one place of Σ, because the conjugate of a chosen place is never chosen. For o in $\Sigma \cup \{\text{none}\}$ let T_o be the set of the $w \in \mathsf{T}$ that are equal or conjugate to o (for $o = $ none: to no place of Σ). The sets T_o partition T and are stable under conjugation. By Input 4(a) each E_{T_o} carries an integral place structure and a filling level $\mathcal{L}_o \in \mathrm{FL}(S, \mathsf{T}_o)$, and Lemma 4.2, applied to T_o, $\mathcal{L}_o$, o and $\mathsf{T}_0 = \mathsf{T}$, gives intermediate groups Z_o of $\mathcal{L}_o$ with (i) and with

$$\mathcal{J}_0(\mathcal{L}_o; Z_o)\, \mathsf{M}(\mathcal{L}_o)(K_1^o)\, c_o \;\le\; \mathcal{J}_0(\mathcal{L}_o; K_1^o)\, \mathsf{M}(\mathcal{L}_o)(Z_o), \tag{2}$$

where $K_1^o = K_{S,\mathsf{T}_o}(1)$. The projections $E_{\mathsf{T}} \to E_{\mathsf{T}_o}$ induce a homomorphism

$$\varphi \colon G(T_S^{\mathrm{lat}}(E_{\mathsf{T}})) \longrightarrow \prod_o G(T_S^{\mathrm{lat}}(E_{\mathsf{T}_o})),$$

which is bijective, continuous and a measurable embedding, since a matrix over E_{T} is a family of matrices over the E_{T_o} and the unitarity condition holds componentwise. Under φ:

(a) for every unit u of E_{T}, $K_{S,\mathsf{T}}(u)$ is the preimage of the product of the groups $K_{S,\mathsf{T}_o}(u_o)$, integrality and congruences being conditions at each place; an element lies in $\mathcal{U}$ exactly if all its components do;

(b) $\psi_{S,\mathsf{T}}(x) = \prod_o \psi_{S,\mathsf{T}_o}(x_o)$, the extension by zero of x being the sum of those of its parts; hence, with Input 5(a), $\chi_g(y) = \prod_o \chi_{g_o}(\varphi(y)_o)$: if one side is non-zero, y lies in $u\,K_{S,\mathsf{T}}(g)$ with $u \in \mathcal{U}$, and then both sides are the value of the character at $g^{-1}\,\mathrm{sd}(u)$, which is additive over the parts;

(c) the measures $\mathsf{M}(\mathcal{L})$ and $\mathsf{M}(\mathcal{L}_o)$ are Haar measures (Input 10(a)); the image of $\mathsf{M}(\mathcal{L})$ under φ is right-invariant, so by the uniqueness of Haar measure (Input 8(d)) it is $\lambda \cdot \prod_o \mathsf{M}(\mathcal{L}_o)$ for some $\lambda \in [0,\infty]$. As both measures give the compact open group K_1, which corresponds to $\prod_o K_1^o$ by (a), a positive finite mass, $0 < \lambda < \infty$.

For a family (Z_o') of subgroups put $Q(Z') = \varphi^{-1}(\prod_o Z_o')$. By (b), (c) and Fubini's theorem,

$$\mathsf{M}(\mathcal{L})(Q(Z')) = \lambda \prod_o \mathsf{M}(\mathcal{L}_o)(Z_o'), \qquad \mathcal{J}_0(\mathcal{L}; Q(Z')) = \lambda^3 \prod_o \mathcal{J}_0(\mathcal{L}_o; Z_o'),$$

the inner integral contributing λ inside the square and the outer one λ once more. Take $Z = Q((Z_o)_o)$. By (a), $K_g = Q((K_g^o)_o) \subseteq Z \subseteq Q((K_1^o)_o) = K_1$, so $Z \in \mathrm{Int}(\mathcal{L})$; (i) holds because it holds on every part; and the product of the inequalities (2) over o, multiplied by λ^4, is (ii), since $\prod_o c_o = b(S)^{6k(\mathfrak{s})\#\Sigma}$. □

LEAN `Filling.IsFillingLevel.exists_intermediateGroup_lines`

A one-sided form of Siegel's formula at T.

Lemma 4.4 (step functions)**.** *Let A be a semilocal field with involution and an integral place structure, n a finite set, $\mathcal{G}$ a subgroup of $\mathrm{GL}_n(A)$ and $\mathcal{G}_0$ a subgroup of $\mathcal{G}$ all of whose elements are integral with integral inverse. Let ι be an index set, $p\colon \iota \to A^n$ a family of points, $f\colon A^n \to [0,\infty]$ a function, $s \subseteq \iota$ a finite set and $\mathrm{wt}\colon \iota \to \mathbb{R}_{\geq 0}$. Suppose that for every $z \in s$ there is a neighbourhood of $p(z)$ such that $\mathrm{wt}(z) \leq f(y)$ for every x in it, every $k \in \mathcal{G}_0$ and every y with $ky = x$. Then there is a function $\Phi\colon A^n \to \mathbb{R}_{\geq 0}$ with compact support such that $\Phi(x+v) = \Phi(x)$ for all x and all v in a neighbourhood of 0, $\Phi(kx) = \Phi(x)$ for all $k \in \mathcal{G}_0$, $\Phi \leq f$, and $\mathrm{wt}(z) \leq \Phi(p(z))$ for every $z \in s$.*

Proof. Almost every element of A is a unit (Input 8(h)), so the units are dense and 0 is a limit of units. As O_A^n is compact and s finite, there is a unit u so small that for every $z \in s$ all points $p(z) + ur$, $r \in O_A^n$, lie in the neighbourhood of the hypothesis. Put

$$\Phi(x) = \max\bigl\{\mathrm{wt}(z) :\ z \in s,\ \exists k \in \mathcal{G}_0,\ u^{-1}(kx - p(z)) \in O_A^n\bigr\},$$

the maximum of the empty set being 0. If z occurs for x, then $kx = p(z) + ur$, so $\mathrm{wt}(z) \leq f(x)$: thus $\Phi \leq f$. The elements of $\mathcal{G}_0$ preserve O_A^n and commute with the scalar u; therefore Φ is invariant under translation by uO_A^n (an open neighbourhood of 0), invariant under $\mathcal{G}_0$ (replace k by kk'), and supported in the union over $z \in s$ of the sets $\mathcal{G}_0^{-1}(p(z) + uO_A^n)$, which is relatively compact because $\mathcal{G}_0$ lies in a compact group of integral matrices. Finally $k = 1$ shows $\Phi(p(z)) \geq \mathrm{wt}(z)$. □

LEAN `Filling.exists_step_function`

Proposition 4.5 (Siegel's formula at T, one-sided)**.** *In Setting 2.3, suppose that E carries Weil data, that S is admissible, that $\hat{g}(S)^{-1}$ is integral off T, and that $\Lambda(S)$, $\Lambda(S)^{-1}$ and $N(S)^{-1}$ are integral off T. Let $f\colon E_{\mathsf{T}}^{I(\mathfrak{s})} \to [0,\infty]$ be a function, $\mathcal{Y}$ a finite set of pairs (c,y) of a class $c \in \mathrm{Cl}(S)$ and a vector $y \in E^{\kappa}$, $t \in E$ with $N(S)^2 < |t_\tau|^2$ for every τ, and $\mathrm{wt}\colon \mathrm{Cl}(S) \times E^{\kappa} \to \mathbb{R}_{\geq 0}$. For a pair (c,y) let $x(c,y) = y_c^{-1} y \in \mathbb{A}_{E,f}^{\kappa}$, y_c the representative of c. Suppose that for every $(c,y) \in \mathcal{Y}$: $N(S)\, y^* y = t\bar{t} - N(S)^2$; every coordinate of $x(c,y)$ is integral off T; and there is a neighbourhood of $\mathrm{tv}(\bar{\pi}(S), t, x(c,y))_{\mathsf{T}}$ such that $\mathrm{wt}(c,y) \leq f(e')$ for every e in it, every $k \in \mathcal{H} \cap K_g$ and every e' with $ke' = e$. Then there is a neighbourhood of 0 in E_{T} such that for every closed and open set L contained in it,*

$$\begin{aligned}\Big(\sum_{(c,y)\in\mathcal{Y}} \mathrm{wt}(c,y)\Big)\cdot \mathrm{vol}(L) \\ \leq\ (1+b(S)^{-6})\,\#\mathrm{Cl}(S)\cdot c_*(S)\cdot\Big(\prod_{\tau}(|t_\tau|^2 - N(S)^2)\Big)^{k(\mathfrak{s})-1} \\ \cdot\ \int \mathbf{1}\big[(Je)_z - t_{\mathsf{T}} \in L\big]\, f(e)\, d\delta^{(\varrho)}(\mathcal{L})(e),\end{aligned}$$

where J is the split Gram matrix of $T_S^{\mathrm{lat}}(E_{\mathsf{T}})$.

Proof. Write $N = N(S)$, $k = k(\mathfrak{s})$, $n = n(\mathfrak{s})$, $\pi_{\mathsf{T}} = \bar{\pi}(S)_{\mathsf{T}}$ (a unit of E_{T}; the letter π alone is the number) and $w_0 = \sum_y \mathrm{wt}$. If $w_0 = 0$ there is nothing to prove. Let $\beta = (t\bar{t} - N^2)/N \in E$; then $\bar{\beta} = \beta$ and $\beta_\tau = (|t_\tau|^2 - N^2)/N > 0$.

The test function. Lemma 4.4, for $A = E_{\mathsf{T}}$, the points $\mathrm{tv}(\bar{\pi}(S), t, x(c,y))_{\mathsf{T}}$, the weights, f and the group $\mathcal{H} \cap K_g$, gives Ψ with compact support, invariant under small translations and under $\mathcal{H} \cap K_g$, with $\Psi \leq f$ and $\mathrm{wt}(c,y) \leq \Psi(\mathrm{tv}(\bar{\pi}(S), t, x(c,y))_{\mathsf{T}})$ on $\mathcal{Y}$. Define Φ_0 on $\mathbb{A}_{E,f}^{\kappa}$ by $\Phi_0(x) = \Psi(\mathrm{tv}(\pi_{\mathsf{T}}, t_{\mathsf{T}}, x_{\mathsf{T}}))$ if x is integral off T, and $\Phi_0(x) = 0$ otherwise. It is locally constant with compact support. It is invariant under $K^{\mathrm{col}}(S)$: an element κ_0 of this group is integral, and the tail vector of $\kappa_0 x$ at T is $\mathrm{loc}_{S,\mathsf{T}}(\mathrm{inc}_S(\kappa_0))$ applied to that of x (Input 4(d), and the definition of inc_S through the lattice basis), where $\mathrm{loc}_{S,\mathsf{T}}(\mathrm{inc}_S(\kappa_0)) \in \mathcal{H} \cap K_g$ because $K^{\mathrm{col}}(S) = \mathrm{inc}_S^{-1}(K_g(S))$ (admissibility and Input 4(b)).

Siegel's formula. Input 8(b), for $K = K^{\mathrm{col}}(S)$, Φ_0 and $\alpha = \beta$ (note $k \geq 3$), in which the weighted sum over the classes is the sum over $\mathrm{Cl}(S)$ because the class automorphism groups are trivial, reads

$$\sum_{c\in\mathrm{Cl}(S)}\ \sum_{x\in E^{\kappa},\ x^*x=\beta} \Phi_0(y_c^{-1}x) = C\cdot\mathfrak{F}, \qquad C = \#\mathrm{Cl}(S)\,|d_E|^{1/4}\prod_{\tau}\frac{\pi^k}{(k-1)!}\beta_\tau^{k-1},$$

with $\mathfrak{F} = \iint \psi_f(\tfrac{1}{2}z(x^*x-\beta))\Phi_0(x)\,dx\,dz$. The pairs of $\mathcal{Y}$ contribute distinct terms on the left, each at least $\mathrm{wt}(c,y)$: indeed $y^*y = \beta$, $x(c,y)$ is integral off T, and $\Phi_0(y_c^{-1}y) = \Psi(\mathrm{tv}(\pi_{\mathsf{T}}, t_{\mathsf{T}}, x(c,y)_{\mathsf{T}})) = \Psi(\mathrm{tv}(\bar{\pi}(S), t, x(c,y))_{\mathsf{T}})$ by the last assertion of Input 4(d). Hence $w_0 \leq C\,|\mathfrak{F}|$, and with $r_0 = (1+b(S)^{-6})/(1+2^{-n}) > 1$ (recall $2^{-n} < 2^{-\varrho(\mathfrak{s})} \leq b(S)^{-6}$) we get the strict inequality $w_0 < r_0\, C\,|\mathfrak{F}|$.

Localising. For $\tau' \in E_{\mathsf{T}}$ put $\mathsf{b}(\tau') = (\pi_{\mathsf{T}}\bar{\pi}_{\mathsf{T}})^{-1}\tau'\bar{\tau}' - N - \beta_{\mathsf{T}}$; as $\pi_{\mathsf{T}}\bar{\pi}_{\mathsf{T}} = N$ in E_{T} and $t\bar{t} = N(\beta+N)$, $\mathsf{b}(t_{\mathsf{T}}) = 0$. For a natural number $M \geq 1$ let $\mathfrak{F}(M,\tau')$ be the integral $\mathfrak{F}$ with z restricted to the codifferent scaled by M and β replaced by $\beta + \widetilde{\mathsf{b}(\tau')}$. By dominated convergence $\mathfrak{F}(M,\tau') \to \mathfrak{F}$ as the scaled codifferents exhaust the self-

adjoint adeles and $\tau' \to t_{\mathsf T}$; so there are a neighbourhood B_0 of $t_{\mathsf T}$ and an integer $M_0 \ge 1$ such that for every multiple M of M_0

$$w_0 < r_0\, C\, |\mathfrak F(M,\tau')| \qquad (\tau' \in B_0). \tag{3}$$

Fix such an M; it will be enlarged once, in the next step. Let m be the finite adele with $Mm = 1$ and $\mathfrak c_M$ the codifferent scaled by M. The measure $\Phi_0(x)\,dx$ is finite, and $\beta + \widetilde{\mathsf b(\tau')}$ is self-adjoint; so by Input 8(c)(i)

$$|\mathfrak F(M,\tau')| = \mathrm{vol}(\mathfrak c_M) \cdot \int \mathbf 1\big[m(x^*x - \beta - \widetilde{\mathsf b(\tau')}) \in \hat O_E\big]\, \Phi_0(x)\,dx.$$

Now, by the definitions of Φ_0 and of $\mathsf b$,

$$\Phi_0(x) = \mathbf 1[x \text{ integral off } \mathsf T] \cdot \Psi(\mathrm{tv}(\pi_{\mathsf T}, t_{\mathsf T}, x_{\mathsf T})),$$
$$y^*y - \beta_{\mathsf T} - \mathsf b(\tau') = y^*y - (\pi_{\mathsf T}\bar\pi_{\mathsf T})^{-1}\tau'\bar\tau' + N.$$

So Input 8(c)(ii), for $a = \mathsf b(\tau')$, for the function f with $f(y) = \Psi(\mathrm{tv}(\pi_{\mathsf T}, t_{\mathsf T}, y))$ and for $a_0 = 3\varrho(\mathfrak s) + 5$, gives a finite constant v_0, which does not depend on τ', with

$$|\mathfrak F(M,\tau')| = \mathrm{vol}(\mathfrak c_M) \cdot v_0 \cdot \int_{\mathcal D(\tau')} \Psi(\mathrm{tv}(\pi_{\mathsf T}, t_{\mathsf T}, y))\,dy,$$

where $\mathcal D(\tau')$ is the set of the $y \in E_{\mathsf T}^{\kappa}$ with $M^{-1}(y^*y - (\pi_{\mathsf T}\bar\pi_{\mathsf T})^{-1}\tau'\bar\tau' + N) \in O_{\mathsf T}$, and with

$$\mathrm{vol}(\mathfrak c_M) \cdot \nu_{\mathsf T}(\delta_{\mathsf T} M O_{\mathsf T}) \cdot v_0 \;\le\; \zeta_{\hat O_E}(3\varrho(\mathfrak s) + 5)\ \mathrm{vol}(\hat O_E)^k \;\le\; (1 + 2^{-n})\ \mathrm{vol}(\hat O_E)^k.$$

The hypotheses of Input 8(c)(ii) hold. First $2(a_0 + 1) = 6\varrho(\mathfrak s) + 12 \le k$, because $1000(2\varrho(\mathfrak s) + 2) \le k$. Secondly, Input 8(c)(iii) for $(u, v, n') = (n(\mathfrak s), 2\varrho(\mathfrak s), 1)$, where $u + v + 4 = 3\varrho(\mathfrak s) + 5$ and $[E : \mathbb Q] \le n(\mathfrak s)[E : \mathbb Q] \le 2^{2\varrho(\mathfrak s)}$, gives $\zeta_{\hat O_E}(3\varrho(\mathfrak s) + 5) \le 1 + 2^{-n} \le 2$; this is also the last inequality of the display.

Averaging over L. Let L be closed and open, so small that $t_{\mathsf T} + L \subseteq B_0$ and that $\Psi(e + \mathrm{tv}(\pi_{\mathsf T}, l, 0)) = \Psi(e)$ for $l \in L$; then $\Psi(\mathrm{tv}(\pi_{\mathsf T}, t_{\mathsf T}, y)) = \Psi(\mathrm{tv}(\pi_{\mathsf T}, t_{\mathsf T} + l, y))$, the tail vector being additive. Let $a < w_0$. Integrating (3) over $\tau' \in t_{\mathsf T} + L$ and inserting the evaluation,

$$a \cdot \mathrm{vol}(L) \;\le\; r_0\, C\, \mathrm{vol}(\mathfrak c_M)\, v_0 \int\!\!\int_{y \in \mathcal D(\tau')} \mathbf 1_L(\tau' - t_{\mathsf T})\, \Psi(\mathrm{tv}(\pi_{\mathsf T}, \tau', y))\,dy\,d\tau'.$$

The function $\Phi(e) = \mathbf 1_L((Je)_z - t_{\mathsf T})\Psi(e)$ is continuous with compact support, and $(J\,\mathrm{tv}(\pi_{\mathsf T}, \tau', y))_z = \tau'$; so by Input 6(b), if the scaled set $MO_{\mathsf T}$ is small enough (replace M by a multiple), the double integral is at most $\mathrm{mod}_{\mathsf T}(\pi_{\mathsf T})\,\nu_{\mathsf T}(\delta_{\mathsf T} M O_{\mathsf T})\,c'$ for every $c' > \int \Phi\, d\delta^{(\varrho)}(\mathcal L)$. Letting $a \to w_0$ and $c' \to \int \Phi\, d\delta^{(\varrho)}(\mathcal L)$, and using $\Psi \le f$,

$$w_0 \cdot \mathrm{vol}(L) \;\le\; r_0\, C\, (1 + 2^{-n})\ \mathrm{vol}(\hat O_E)^k\, \mathrm{mod}_{\mathsf T}(\pi_{\mathsf T}) \int \mathbf 1[(Je)_z - t_{\mathsf T} \in L] f(e)\, d\delta^{(\varrho)}(\mathcal L)(e).$$

The constant. The modulus is multiplicative and takes the same value at $\bar\pi_{\mathsf T}$ and at $\pi_{\mathsf T}$ (Input 8(h)); so

$$\mathrm{mod}_{\mathsf T}(\pi_{\mathsf T})^2 = \mathrm{mod}_{\mathsf T}(\pi_{\mathsf T}\bar\pi_{\mathsf T}) = \mathrm{mod}_{\mathsf T}(N_{\mathsf T}) = N^{-2f(E)}$$

(Input 4(b); N and N^{-1} are integral off $\mathsf T$), and $\mathrm{mod}_{\mathsf T}(\pi_{\mathsf T}) = N^{-f(E)}$. Further $\prod_\tau \beta_\tau^{k-1} = (\prod_\tau (|t_\tau|^2 - N^2))^{k-1} N^{-(k-1)f(E)}$. Hence the constant is $(1 + b(S)^{-6})\,\#\mathrm{Cl}(S)\,c_*(S)\,(\prod_\tau (|t_\tau|^2 - N^2))^{k-1}$. □

LEAN `Filling.IsFillingLevel.siegel_sum_le_lintegral_quadric`

The top kernel dominates the phase sums.

Proposition 4.6 (blocks and the top kernel)**.** *In Setting 2.3, suppose that E carries Weil data, that S is admissible, that $\hat{g}(S)^{-1}$ is integral off T, and that $\Lambda(S)$, $\Lambda(S)^{-1}$ and $N(S)^{-1}$ are integral off T. Let σ be a side, $Z \in \mathrm{Int}(\mathcal{L})$, T_0 a finite set of units of E, $\mathcal{J}$ a finite index set, and for $j \in \mathcal{J}$ let c_j, c_j' be classes, $\gamma_j \in G_S(E)$ and $k_j \in K(S)$; let t be a unit of E. Suppose that*

(a) *the tuples $(c_j, c_j', \mathrm{red}_S(k_j), \gamma_j)$ are pairwise distinct;*
(b) *$\gamma_j \in \mathcal{H}_\varrho(T_S^{\mathrm{rat}}(E))$ and $Z_S(\gamma_j)_{\varrho\varrho} = t$ for all j, and $N(S)^2 < |t_\tau|^2$ for all τ;*
(c) *$\mathrm{loc}_{S,\mathsf{T}}(k_j) \in Z$ and $\mathrm{pos}_S(c_j, c_j'; \gamma_j)$ is integral off T, for all j.*

Let $j_0 \in \mathcal{J}$, let R be a complex matrix and ρ a real function, both indexed by the maps p from $\{0, \dots, \varrho(\mathfrak{s}) - 1\}$ to T_0, and r a real number. Put $\omega_p = (p \,|\, t)_{\mathsf{T}}$,

$$y_j = r^2 \Big\| \sum_p a^\sigma_{S,\mathsf{T}}(c_j, \mathrm{red}_S(k_j), c_j'; w_\varrho((p \,|\, t))\gamma_j) \Big\|^2,$$
$$G = \Big(\prod_\tau (|t_\tau|^2 - N(S)^2) \Big)^{k(\mathfrak{s})-1},$$

and suppose further that

(d) *for every j, R is the Gram matrix of the vectors $\rho(p) \cdot \mathrm{J}(dy, W_S^\sigma(\cdot).; \gamma_{j,p})$, where $\gamma_{j,p} = \mathrm{r}_S^\infty(w_\varrho((p \,|\, t))\gamma_j)$;*
(e) *$\rho(p) \cdot \mathsf{h}_\varrho(\mathcal{L}; \omega_p, 1) = r\sqrt{G}$ for all p;*
(f) *$\mathrm{pos}_S(c_j, c_j'; w_\varrho((p \,|\, t))\gamma_j)$ is integral off T for all j and p.*

Then there is a neighbourhood of 0 in E_{T} such that for every open and compact set L contained in it with $0 \in L$,

$$\sum_{j \in \mathcal{J}} y_j \;\le\; (1 + b(S)^{-6}) \cdot a_*(S) \cdot \mathrm{Re} \sum_{p,q} R_{pq} \, \frac{\mathcal{K}(L; Z; \omega_p, \omega_q)}{\mathrm{vol}(L) \cdot \mathrm{mr}(Z)}.$$

Proof. Write $l_j = \mathrm{pos}_S(c_j, c_j'; \gamma_j)$ and let $\omega^{(j)} \in E^\kappa$ be the κ-part of $\gamma_j z$. By Input 4(d), $l_j \in \mathcal{H}_\varrho$, $l_j z = \mathrm{tv}(\bar{\pi}(S), t, y_{c_j}^{-1}\omega^{(j)})$ and $N(S)\,\omega^{(j)*}\omega^{(j)} = t\bar{t} - N(S)^2$.

Step 1: the constant. Let $D_0 = \#\overline{\mathcal{S}}^S \cdot \mathrm{uo}(S)$, so that $a_*(S) = D_0 \cdot \#\mathrm{Cl}(S) \cdot c_*(S)$. We claim

$$\mathrm{mr}(Z) \;\le\; \theta_n(\mathcal{L})(K_g) \cdot \mathsf{M}(\mathcal{L})(K_g)^2 \cdot \#\,\mathrm{Cos}(Z) \cdot D_0. \tag{4}$$

Indeed Z is the union of $\#\,\mathrm{Cos}(Z)$ translates of K_g, so its measure $\mathsf{M}(\mathcal{L})(Z)$ is at most $\#\,\mathrm{Cos}(Z)$ times $\mathsf{M}(\mathcal{L})(K_g)$; and $\mathsf{v}(\mathcal{L})^{-2} = \mathrm{uo}(S)^2$ by Input 4(b). We apply Input 4(c) to the subgroup $B = \mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ of G_S^{lat}, written $\mathcal{H}$, and to the measure $\mu = \theta_n(\mathcal{L})$. Its two hypotheses hold: $\theta_n(\mathcal{L})$ is carried by $\mathcal{H}$ at T (Input 10(b)), and every element of $\mathcal{H}$ at T is the image of an element of $\mathcal{H}$ that is integral off T (Input 4(b)); and $\theta_n(\mathcal{L})$ is invariant under right translation by every element of $\mathcal{H}$ at T (Input 10(b)), in particular by the image of every element of B, which is the formal hypothesis. Hence $\#\overline{\mathcal{H}}^S \cdot \theta_n(\mathcal{L})(K_g) = \theta_n(\mathcal{L})(K_1) = 1$, the last by Input 10(a); with $\#\overline{\mathcal{S}}^S = \#\overline{\mathcal{H}}^S\,\mathrm{uo}(S)$ this gives $\theta_n(\mathcal{L})(K_g)\,D_0 = \mathrm{uo}(S)^2$, whence (4).

Step 2: packets. Group the indices by $\mathsf{g}(j) = (c_j, \omega^{(j)})$. Fix a value z_0 of g and let Θ_0 be the set of the pairs $\theta = (j, b)$ with $\mathsf{g}(j) = z_0$ and $b \in \mathrm{Cos}(Z)$. For such θ put

$l_\theta = \mathrm{loc}_{S,\mathsf{T}}(l_j)^{-1} \in \mathcal{H}_\varrho$; then $l_\theta^{-1} z = e_0$, the tail vector of z_0 at T, the same for all θ. As $\mathrm{loc}_{S,\mathsf{T}}(k_j) \in Z$, there is exactly one coset $A(j,b)$ with $\mathrm{loc}_{S,\mathsf{T}}(k_j)^{-1} a_b a_{A(j,b)}^{-1} \in K_g$ (Input 5(a)); put $n_\theta = (b, A(j,b))$.

The pairs $(K_g l_\theta, n_\theta)$ are distinct. Let $\theta = (j,b)$, $\theta' = (j',b')$ with $l_\theta l_{\theta'}^{-1} \in K_g$ and $n_\theta = n_{\theta'}$. Then $b = b'$ and $A(j,b) = A(j',b)$, so $\mathrm{loc}_{S,\mathsf{T}}(k_j)^{-1} \mathrm{loc}_{S,\mathsf{T}}(k_{j'}) \in K_g$ and $\mathrm{red}_S(k_j) = \mathrm{red}_S(k_{j'})$ (Input 4(b)); also $c_j = c_{j'}$. The vectors $\gamma_j z$ and $\gamma_{j'} z$ lie in the span of κ and z, have the same κ-part and, as $h(z, \gamma_j z) = t = h(z, \gamma_{j'} z)$, the same coefficient at z; so the element $\gamma_j^{-1}\gamma_{j'} \in \mathcal{H}_\varrho$ fixes z, and it lies in $\mathcal{H}$, hence in the Bessel subgroup. Its position $\mathrm{pos}_S(c'_j, c'_{j'}; \gamma_j^{-1}\gamma_{j'}) = l_j^{-1} l_{j'}$ is integral off T and lies in K_g at T, hence in $K_g(S)$ (Input 4(b)); so $c'_j = c'_{j'}$ and $\gamma_j^{-1}\gamma_{j'}$ lies in $\mathcal{U}_{S,c'_j} \subseteq \mathcal{U}$ (Input 1(c)). But $\mathcal{H}_\varrho \cap \mathcal{U} = 1$, so $\gamma_j = \gamma_{j'}$, and $j = j'$ by (a).

By Input 5(g), with $v_\theta(p) = \mathcal{J}(Z; \omega_p, l_\theta)_{n_\theta}$: for all e near e_0, all $k \in \mathcal{H} \cap K_g$ and all e' with $ke' = e$,

$$\theta_n(\mathcal{L})(K_g) \sum_{\theta \in \Theta_0} \left(\mathrm{Re}\; v_\theta^* R v_\theta\right)^+ \;\le\; \mathcal{E}(Z; R, \omega, e').$$

By (d), $v_\theta^* R v_\theta = \left\| \sum_p \rho(p)\, v_\theta(p)\, \mathrm{J}(dy, W_S^\sigma(\cdot).; \mathrm{r}_S^\infty(w_\varrho((p\,|\,t))\gamma_j)) \right\|^2$; by the unfolding (Input 4(f), with (f) and the choice of $A(j,b)$) and by (e), the vector inside the norm equals $r\sqrt{G} \cdot \mathsf{M}(\mathcal{L})(K_g) \cdot \sum_p a_{S,\mathsf{T}}^\sigma(c_j, \mathrm{red}_S(k_j), c'_j; w_\varrho((p\,|\,t))\gamma_j)$. Hence $v_\theta^* R v_\theta = G\, \mathsf{M}(\mathcal{L})(K_g)^2\, y_j$ for every b, and with (4)

$$\begin{aligned} \mathcal{E}(Z; R, \omega, e') \;&\ge\; \theta_n(\mathcal{L})(K_g)\, \#\,\mathrm{Cos}(Z)\, G\, \mathsf{M}(\mathcal{L})(K_g)^2 \sum_{\mathrm{g}(j) = z_0} y_j \\ &\ge\; \frac{G \cdot \mathrm{mr}(Z)}{D_0} \sum_{\mathrm{g}(j) = z_0} y_j =: \mathrm{wt}(z_0). \end{aligned} \tag{5}$$

Step 3: Siegel's formula. Apply Proposition 4.5 to the set $\mathcal{Y}$ of the values of g, the weights wt and $f = \mathcal{E}(Z; R, \omega, \cdot)$. The quadric condition was noted; $y_{c_j}^{-1}\omega^{(j)}$ is integral off T because l_j is and $\Lambda(S)^{\pm 1}$ are; the orbit condition is (5). For L small, open and compact with $0 \in L$ (so closed, with $0 < \mathrm{vol}(L) < \infty$),

$$\begin{aligned} \frac{G\ \mathrm{mr}(Z)}{D_0} \Big(\sum_j y_j \Big)\, \mathrm{vol}(L) \;&\le\; (1 + b(S)^{-6}) \#\mathrm{Cl}(S)\, c_*(S)\, G \\ &\quad \cdot \int \mathbf{1}\big[(Je)_z - t_\mathsf{T} \in L\big] \mathcal{E}(Z; R, \omega, e)\, d\delta^{(\varrho)}(\mathcal{L})(e). \end{aligned}$$

The matrix R is positive semidefinite, being a Gram matrix (here j_0 is used), and $(\omega_p)_\varrho = t_\mathsf{T}$; so by Input 5(f) the integral is at most $\mathrm{Re} \sum_{p,q} R_{pq} \mathcal{K}(L; Z; \omega_p, \omega_q)$. Dividing by $G\ \mathrm{mr}(Z)\ \mathrm{vol}(L)/D_0$, which is positive and finite (Input 5(c)), gives the claim. □

LEAN `Filling.IsFillingLevel.sum_blocks_le_topKernel`

The finite sieve system.

Proposition 4.7 (the system at T)**.** *In Setting 2.3, suppose that E carries Weil data, that S is admissible and that $\hat{g}(S)^{-1}$ is integral off T. Let $\Sigma \subseteq \mathrm{Ch}_0(S)$ and let $\mathbf{d}$ be frame-vector data for S. Then there is $Z \in \mathrm{Int}(\mathcal{L})$ such that*

(i) *$\mathrm{loc}_{S,\mathsf{T}}(k) \in Z$ for every $k \in K(S)$ with $\mathrm{red}_S(k) \in \mathrm{Fix}_S(\Sigma, \mathbf{d})$, and*

(ii) *for every open additive subgroup L of $E_{\mathsf T}$ that is compact, the kernels*

$$J_L(j,p,q) = \mathcal{I}_j(\mathcal{L};p,q;W_Z(\cdot),1)\cdot \mathrm{mr}(Z)^{-1} \qquad (j \le \varrho(\mathfrak{s})),$$
$$J_L(j,p,q) = \mathcal{K}(L;Z;p,q)\cdot \mathrm{vol}(L)^{-1}\ \mathrm{mr}(Z)^{-1} \quad (j > \varrho(\mathfrak{s}))$$

form, with the maps $c \mapsto u(c)$ and $x \mapsto g(S)_{\mathsf T}^{-1}x^{-1}$, the character $\psi_{S,\mathsf T}$, the bottom bound $(1+b(S)^{-6})\,b(S)^{-6k(\mathfrak{s})\cdot\#\Sigma}$, the weights $\Lambda_{n(\mathfrak{s})^6}(\cdot;\cdot)$ and the frequency gain $\beta_{S,\mathsf T}(\cdot)$, a sieve system of depth $\varrho(\mathfrak{s})$ on $E_{\mathsf T}$ (Definition 2.4).

Proof. Let Z be the group of Proposition 4.3; (i) is its first property. Write $b = b(S)$, $k = k(\mathfrak{s})$, $n = n(\mathfrak{s})$, $\varrho = \varrho(\mathfrak{s})$, $W = W_Z(\cdot)$, $\psi = \psi_{\mathsf T} = \psi_{S,\mathsf T}$.

Frequency bounds. Let ξ be a unit and ω as in Input 5(d). With $K = n^6$ and $t = k - n^7$ (admissible choices, as $10^{10}n^4 \le n^6 \le n^7 \le k$), Input 5(d) gives $|\mathcal{I}_j(\mathcal{L};p,q;W,\omega)|/\,\mathrm{mr}(Z) \;\le\; [\xi]^{(k-n^7)/2}\,\mathrm{den}(\xi)^{-6}(2/\mathrm{mod}_{\mathsf T}(g_{\mathcal L}))^{n^6}\Lambda_{n^6}(j;p)\Lambda_{n^6}(j;q)$. By Input 4(b), $2/\mathrm{mod}_{\mathsf T}(g_{\mathcal L}) = 2g(S)^{2f(E)} \le b^{1+46f(E)} \le b^{47f(E)}$, and $47 \le n^3$; so

$$\frac{|\mathcal{I}_j(\mathcal{L};p,q;W,\omega)|}{\mathrm{mr}(Z)} \;\le\; \beta_{S,\mathsf T}(\xi)\cdot\Lambda_{n^6}(j;p)\,\Lambda_{n^6}(j;q). \tag{6}$$

The axioms. $\psi(0)=1$. *Steps below the top* ($i<\varrho$): W is a cut Bessel function for $\mathcal{L}$ and the majorant of the floor form at (i,p,q) has a finite integral (Input 5(h)), and $\mathcal{L}$ has a gauge (Input 10(a)); so by the descent (Input 10(c)) the function $c \mapsto \psi(\xi c)J_L(i+1,p[i\mapsto u(c)],q[i\mapsto u(c)])$ is integrable with integral $\mathcal{I}_i(\mathcal{L};p,q;W,\omega_\xi)/\,\mathrm{mr}(Z)$; for $\xi=0$ this is $J_L(i,p,q)$, and for a unit ξ it is bounded by (6). *The step at the top* ($i=\varrho$): the correlations $\mathcal{J}(Z;p,l)$ do not depend on the entry p_ϱ, and almost every c is a unit (Input 8(h)); so by Fubini's theorem and the invariance of the Haar measure

$$\int \psi(\xi c)\,\mathcal{K}(L;Z;p[\varrho\mapsto c],q[\varrho\mapsto c])\,dc$$
$$= \Big(\int_L \psi(-\xi x)\,dx\Big)\int \psi(\xi\,h(z,l^{-1}z))\big\langle \mathcal{J}(Z;p,l),\mathcal{J}(Z;q,l)\big\rangle\,d\mu^{\mathcal L}_{\varrho,2}(l),$$

and the last integral is $\mathcal{I}_\varrho(\mathcal{L};p,q;W,\omega_\xi)$ (Input 5(e)). After division by $\mathrm{vol}(L)\,\mathrm{mr}(Z)$: for $\xi=0$ the first factor is $\mathrm{vol}(L)$ and we get $J_L(\varrho,p,q)$; for a unit ξ the first factor has modulus at most $\mathrm{vol}(L)$ and (6) applies. *Positivity*: for sequences $a_1,\dots,a_m$ with a common ϱ-th term the matrix $(\mathcal{K}(L;Z;a_i,a_{i'}))$ is hermitian, and for a vector x its quadratic form is the number $\mathcal{Q}$ of Input 5(f) for the positive semidefinite matrix $R=(\bar{x}_i x_{i'})$, hence ≥ 0. *Continuity* is Input 5(e). *Unequal entries* ($i<\varrho$, $\xi = g(S)_{\mathsf T}^{-1}(p_i^{-1}-q_i^{-1})$ a unit): this is (6) for $j=i+1$, $\omega=1$, the second alternative of Input 5(d), as $g_{\mathcal L} = \hat g(S)_{\mathsf T}$.

The bottom bound. By the last assertion of Input 5(h) the inner integral of $\mathcal{I}_0(\mathcal{L};Z)$ at x has the modulus $\mathsf{v}(\mathcal{L})\cdot|\mathsf{A}(\mathcal{L};W,x)|$; with Input 10(d) this gives

$$\big|\mathcal{I}_0(\mathcal{L};p,q;W,1)\big|\cdot\mathsf{v}(\mathcal{L})^2 \;\le\; \mathsf{v}(\mathcal{L})^2\int\big|\mathsf{A}(\mathcal{L};W,x)\big|^2\,d\mathsf{M}(\mathcal{L})(x) = \mathcal{I}_0(\mathcal{L};Z).$$

By Proposition 4.3(ii), $\mathcal{I}_0(\mathcal{L};Z)\,\mathsf{M}(\mathcal{L})(K_1)\,b^{6k\#\Sigma} \le \mathcal{I}_0(\mathcal{L};K_1)\,\mathsf{M}(\mathcal{L})(Z)$; and by the bottom value for the intermediate group K_1 with $t=0$, by $\mathrm{vol}(O_{\mathsf T}\setminus O_{\mathsf T}^\times)\le 1$ and by $\mathsf{M}(\mathcal{L})(K_1)\le 1+2^{-n}$ (Inputs 5(b) and 10(a)),

$$\mathcal{I}_0(\mathcal{L};K_1) \le \mathsf{M}(\mathcal{L})(K_1)\,\mathsf{M}(\mathcal{L})(K_g)\,(1+2^{-n}+2^{-n}) \le \mathsf{M}(\mathcal{L})(K_1)\,\mathsf{M}(\mathcal{L})(K_g)\,(1+b^{-6}),$$

since $2^{-n}+2^{-n}=2^{-\varrho}\le b^{-6}$. Together,

$$|\mathcal{J}_0(\mathcal{L};p,q;W,1)|\,\mathsf{v}(\mathcal{L})^2\,b^{6k\#\Sigma}\le \mathsf{M}(\mathcal{L})(Z)\,\mathsf{M}(\mathcal{L})(K_g)\,(1+b^{-6}),$$

that is $|J_L(0,p,q)|\le(1+b^{-6})\,b^{-6k\#\Sigma}$. □

LEAN `Filling.IsFillingLevel.exists_finite_sieveSystem`

5 The main-term estimate: proof of Theorem D

Write $b=b(S)$, $k=k(\mathfrak{s})$, $n=n(\mathfrak{s})$, $\varrho=\varrho(\mathfrak{s})$, $\nu=\nu(S)$ and $y_\Sigma=b^{-6k\#\Sigma}$; recall $\#\Sigma\le\#\mathrm{Ch}_0(S)=f(E)$. The amplitude sum of the statement is $A=A_S^{\mathrm{full}}(G_S(E);\cdot,\cdot,\cdot)$.

Proof of Theorem D. Step 1: the crude estimate. We apply Input 3 with $\Xi=G_S(E)$ (which is stable), $\Omega=\mathrm{Fix}_S(\Sigma,\mathbf{d})$, $X=q_0(S)^{\#\Sigma}$, $C=y_\Sigma\mathsf{d}(S)$, $\omega_0=(1+b^{-4})\,y_\Sigma\mathsf{d}(S)$, and with $\mathcal{R}$ the set of all links if $\Sigma\neq\mathrm{Ch}_0(S)$ and the empty set if $\Sigma=\mathrm{Ch}_0(S)$. Its hypotheses hold:

- every $s\in\Omega$ fixes norm at least X, by the triples $(0,w,\epsilon_w)$, $w\in\Sigma$;
- $\mathrm{tl}(S)^{20}\mathsf{d}_1(S)\le C$: by admissibility $\mathrm{tl}(S)^{44}\mathsf{d}_1(S)\le\mathsf{d}(S)$, and $\mathrm{tl}(S)^{-24}=b^{-6kf(E)}\le y_\Sigma$; hence also $\mathsf{d}_1(S)\le C$, as $\mathrm{tl}(S)\ge 2$;
- if some link is not in $\mathcal{R}$, then $\Sigma=\mathrm{Ch}_0(S)$, so $X=q_0(S)^{f(E)}\ge b^{10f(E)}$ and $\mathrm{tl}(S)^{12}X^{-k}\mathsf{d}(S)\le b^{3kf(E)-10kf(E)}\mathsf{d}(S)\le y_\Sigma\mathsf{d}(S)=C$.

If moreover the link energy is at most $\omega_0\nu^2$, Input 3 gives

$$\mathrm{En}_S(A;\Omega)\le\big((1+b^{-4})^3+b^{-12}\big)\,y_\Sigma\mathsf{d}(S)\le(1-b^{-4})(1+9b^{-4})\,y_\Sigma\mathsf{d}(S),$$

the last step because, with $\varepsilon=b^{-4}\le 10^{-12}$, $(1-\varepsilon)(1+9\varepsilon)-(1+\varepsilon)^3-\varepsilon^3=5\varepsilon-12\varepsilon^2-2\varepsilon^3\ge 0$. So it remains to show

$$\sum_{c,c'}\sum_{s\in\Omega}\sum_{\Lambda\in\mathcal{R}}\big\|\mathrm{Bl}(c,s,c',\Lambda)\big\|^2\;\le\;(1+b^{-4})\,y_\Sigma\,\mathsf{d}(S)\,\nu^2, \tag{7}$$

where $\mathrm{Bl}(c,s,c',\Lambda)$ is the *block* $A_S^{\mathrm{cut}}(\{\gamma:\mathfrak{g}_S(\gamma)\neq 0,\ \mathrm{link}(\gamma)=\Lambda\};c,s,c')$. If $\Sigma=\mathrm{Ch}_0(S)$ the sum is empty. Assume $\Sigma\neq\mathrm{Ch}_0(S)$; it suffices to bound the sum over a finite set $\mathcal{F}$ of tuples $j=(c_j,s_j,c_j',\Lambda_j)$ with non-zero blocks.

Step 2: blocks as limits. Let $j\in\mathcal{F}$. As $s_j\in\Omega$ and $\Sigma\neq\mathrm{Ch}_0(S)$, there is $w\in\mathrm{Ch}_0(S)$ at which all leading minors of the frame Gram matrix of $(s_j)_w$ are non-zero. For a term γ over (c_j,s_j,c_j') the frame Gram matrix of $\mathrm{pos}_S(c_j,c_j';\gamma)$ is the image of $Z_S(\gamma)$ and reduces to that of $(s_j)_w$ at w (Input 1(e)); so all leading minors of $Z_S(\gamma)$ are non-zero. Input 4(e) gives a unit t_j, an element $\gamma_j\in\mathcal{H}_\varrho(T_S^{\mathrm{rat}}(E))$ with $Z_S(\gamma_j)_{\varrho\varrho}=t_j$ and $N(S)^2<|(t_j)_\tau|^2$, an element $k_j\in K(S)$ with $\mathrm{red}_S(k_j)=s_j$, such that $\Lambda_j=\mathrm{link}(w_\varrho(1)\gamma_j)$, and vectors $L_{j,p}$ with

$$\mathrm{Bl}(j)=\sum_p L_{j,p},\qquad L_{j,p}=\lim_{\mathsf{T}}\ a_{S,\mathsf{T}}^{\mathrm{cut}}(c_j,s_j,c_j';w_\varrho((p\,|\,t_j))\gamma_j).$$

Hence it suffices to prove, for every finite set T_0 of units of E containing all t_j, with p running over the maps from $\{0,\dots,\varrho-1\}$ to T_0, and for arbitrarily large T,

$$\sum_{j\in\mathcal{F}}\Big\|\sum_p a_{S,\mathsf{T}}^{\mathrm{cut}}(c_j,s_j,c_j';w_\varrho((p\,|\,t_j))\gamma_j)\Big\|^2\;\le\;(1+b^{-4})\,y_\Sigma\,\mathsf{d}(S)\,\nu^2\,: \tag{8}$$

the partial sums over such p exhaust the sum over all p, and a limit of quantities that are bounded for arbitrarily large indices is bounded.

Step 3: the places. By Input 4(a) there are arbitrarily large T, stable under conjugation, off which $t^{\pm1}$ ($t \in \mathsf{T}_0$), $\hat{g}(S)^{-1}$, $N(S)^{-1}$ and $\Lambda(S)^{\pm1}$ are integral, and also the finitely many positions $\mathrm{pos}_S(c_j, c_j'; \gamma_j)$ and $\mathrm{pos}_S(c_j, c_j'; w_\varrho((p\,|\,t_j))\gamma_j)$. Fix such T, an integral place structure and a filling level $\mathcal{L} \in \mathrm{FL}(S, \mathsf{T})$ (Input 4(a)), and let Z be the intermediate group of Proposition 4.7 for Σ and $\mathbf{d}$. Then $\mathrm{loc}_{S,\mathsf{T}}(k_j) \in Z$ for all j, because $\mathrm{red}_S(k_j) = s_j \in \mathrm{Fix}_S(\Sigma, \mathbf{d})$.

Step 4: the top kernel. Fix a value t of $j \mapsto t_j$ and let $\mathcal{J}_t$ be its fibre. For a map p let $x_\tau(p,t)$ be the sequence $a \mapsto u(\mathrm{fs}_S(\tau,a)\cdot((p\,|\,t)_a)_\tau)$ of Input 6(a), and put

$$R^{(t)}_{pq} = \prod_\tau \mathrm{bl}_\tau(x_\tau(p,t), x_\tau(q,t)),$$

$$r = \frac{1}{\#\mathrm{Bc}(S)} \prod_\tau \Big(\sqrt{\mathrm{oc}(\mathfrak{s})} \prod_{a \le \varrho} \mathrm{fs}_S(\tau,a)^{\,k-1+2(\varrho-a)} \Big).$$

We check the hypotheses of Proposition 4.6 for $\mathcal{J}_t$, the side cut, the elements k_j, the matrix $R^{(t)}$ and r. (a): if two indices of $\mathcal{J}_t$ have the same tuple $(c, c', \mathrm{red}_S(k), \gamma)$, they have the same s and the same link $\mathrm{link}(w_\varrho(1)\gamma)$, so they are equal. (b), (c), (f) hold by Steps 2 and 3. (d): the rescaled image at τ of $w_\varrho((p\,|\,t))\gamma_j$ is $w_\varrho(x_\tau(p,t)) \cdot \mathrm{r}^\infty_S(\gamma_j)_\tau$ (Input 4(d)), the element $\mathrm{r}^\infty_S(\gamma_j)_\tau$ lies in $\mathcal{H}_\varrho$, and its frame Gram matrix has the entry $\mathrm{fs}_S(\tau,\varrho)\,t_\tau = t_\tau/N(S) = x_\tau(p,t)_\varrho$ at (ϱ,ϱ); so by the band limits (Input 6(a)) and because the correlation of a product of functions on a product of groups is the product of the correlations, $R^{(t)}$ is the Gram matrix of the vectors $\rho_t(p) \cdot \mathrm{J}(dy, W_S^{\mathrm{cut}}(\cdot).; \mathrm{r}^\infty_S(w_\varrho((p\,|\,t))\gamma_j))$, for every $j \in \mathcal{J}_t$, where

$$\rho_t(p) = \prod_\tau \frac{\sqrt{\mathrm{oc}(\mathfrak{s})}\,(|t_\tau|^2/N(S)^2 - 1)^{(k-1)/2}}{\#I_\tau} \prod_{a<\varrho} \big(\mathrm{fs}_S(\tau,a)\,|(p_a)_\tau|\big)^{k+1+2(\varrho-a-1)}.$$

(e): the head density of the unit on the real place is

$$\mathsf{h}_\varrho(\mathcal{L}; \omega_p, 1) = \prod_{a<\varrho} \mathrm{mod}_{\mathsf{T}}((p_a)_{\mathsf{T}})^{(k+1+2(\varrho-a-1))/2},$$

and by Input 4(b), for the unit p_a of E, which is integral off T with its inverse, $\mathrm{mod}_{\mathsf{T}}((p_a)_{\mathsf{T}})^{1/2} = \prod_\tau |(p_a)_\tau|^{-1}$. As $k+1+2(\varrho-a-1) = k-1+2(\varrho-a)$,

$$\mathsf{h}_\varrho(\mathcal{L}; \omega_p, 1) = \prod_{a<\varrho} \prod_\tau |(p_a)_\tau|^{-(k-1+2(\varrho-a))},$$

which cancels the powers of the $|(p_a)_\tau|$ in $\rho_t(p)$. What remains of $\rho_t(p)$ is the product over τ of $\sqrt{\mathrm{oc}(\mathfrak{s})}\,(\#I_\tau)^{-1} \prod_{a<\varrho} \mathrm{fs}_S(\tau,a)^{\,k-1+2(\varrho-a)}$ and of

$$(|t_\tau|^2/N(S)^2 - 1)^{(k-1)/2} = (|t_\tau|^2 - N(S)^2)^{(k-1)/2} \cdot \mathrm{fs}_S(\tau,\varrho)^{\,k-1},$$

by $\mathrm{fs}_S(\tau,\varrho) = N(S)^{-1}$; the last factor is the term $a = \varrho$ of the product in r. With $\prod_\tau \#I_\tau = \#\mathrm{Bc}(S)$ this gives $\rho_t(p) \cdot \mathsf{h}_\varrho(\mathcal{L}; \omega_p, 1) = r\sqrt{G}$, where $G = (\prod_\tau (|t_\tau|^2 - N(S)^2))^{k-1}$. Proposition 4.6 gives, for every sufficiently small open compact $L \ni 0$,

$$\begin{aligned} r^2 \sum_{j \in \mathcal{J}_t} \Big\| \sum_p a^{\mathrm{cut}}_{S,\mathsf{T}}(c_j, s_j, c_j'; w_\varrho((p\,|\,t))\gamma_j) \Big\|^2 \\ \le\ (1 + b^{-6})\, a_*(S) \cdot \mathrm{Re} \sum_{p,q} R^{(t)}_{pq}\, \frac{\mathcal{K}(L; Z; \omega_p, \omega_q)}{\mathrm{vol}(L)\ \mathrm{mr}(Z)}. \end{aligned} \tag{9}$$

As E_{T} has a basis of neighbourhoods of 0 consisting of compact open additive subgroups, one such subgroup L serves all the finitely many t.

Step 5: the sieve. By Proposition 4.7(ii) the kernels J_L form a sieve system with bottom bound $\mathcal{E}_0 = (1+b^{-6})\,y_\Sigma$, and $J_L(n,\omega_p,\omega_q)$ is the quotient on the right of (9). Summing (9) over the values t and applying the sieve (Input 6(a), with U the set of these values),

$$\begin{aligned} r^2\cdot(\text{left side of (8)}) \;\le\; (1+b^{-6})\,a_*(S)\cdot\prod_{a\le\varrho}\frac{\operatorname{vol}(\hat O_E)}{\prod_\tau \operatorname{fs}_S(\tau,a)^2} \\ \cdot\Big(\prod_\tau\frac{1+b^{-10}}{\deg\mathfrak{B}_\tau(S)}\,(1+b^{-6})\,y_\Sigma+\frac{\deg(S)^{-1}}{b^{6kf(E)+10}}\Big). \end{aligned}$$

Step 6: the numbers. By admissibility,

$$a_*(S)\le(1+b^{-9})\,\mathsf{d}(S)\,\deg(S)\,\operatorname{oc}(\mathfrak{s})^{f(E)}\operatorname{vol}(\hat O_E)^{-n}(\nu\operatorname{fs}(S)/\#\mathrm{Bc}(S))^2,$$

and $\operatorname{fs}(S)=\prod_\tau\prod_{a\le\varrho}\operatorname{fs}_S(\tau,a)^{\,k+2(\varrho-a)}$, so that

$$\operatorname{oc}(\mathfrak{s})^{f(E)}\cdot\operatorname{fs}(S)^2\cdot\#\mathrm{Bc}(S)^{-2}\cdot\prod_{a\le\varrho}\prod_\tau\operatorname{fs}_S(\tau,a)^{-2}=r^2.$$

Further $(1+b^{-10})^{f(E)}\le\exp(f(E)\,b^{-10})\le 1+b^{-9}$ because $f(E)\le b/1000$, and $b^{-6kf(E)-10}\le b^{-10}y_\Sigma$. Hence

$$r^2\cdot(\text{left side of (8)}) \;\le\; r^2\,\nu^2\,\mathsf{d}(S)\,y_\Sigma\cdot(1+b^{-6})(1+b^{-9})((1+b^{-9})(1+b^{-6})+b^{-10}),$$

and the last factor is at most $1+b^{-4}$ for $b\ge1000$. As $r>0$, this is (8). □

6 The second moment with constant one: proof of Theorem C

Proof of Theorem C. By downward induction on Σ in the finite set of the subsets of $\mathrm{Ch}_0(S)$: we assume the statement for all $\Sigma'\supsetneq\Sigma$ and all V, Θ, u, $\mathbf{d}$. Write $b=b(S)$, $k=k(\mathfrak{s})$, $\varrho=\varrho(\mathfrak{s})$, $q_0=q_0(S)$, $\Theta_{\mathrm{tot}}=\sum_s\Theta(s)$ and $y_\Sigma=b^{-6k\#\Sigma}$, and suppose, for a contradiction, that

$$\Theta_{\mathrm{tot}}>(1+9b^{-4})\,\mathsf{d}(S)\,y_\Sigma. \tag{10}$$

Claim: $\sum_{s\notin\mathrm{Fix}_S(\Sigma,\mathbf{d})}\Theta(s)\le b^{-4}\,\Theta_{\mathrm{tot}}$. Granting this, the hypothesis on the energies and Theorem D give

$$\begin{aligned}(1-b^{-4})\,\Theta_{\mathrm{tot}}\le\sum_{s\in\mathrm{Fix}_S(\Sigma,\mathbf{d})}\Theta(s)&\le\mathrm{En}_S(A_S^{\mathrm{full}}(G_S(E);\cdot,\cdot,\cdot);\mathrm{Fix}_S(\Sigma,\mathbf{d}))\\&\le(1-b^{-4})(1+9b^{-4})\,\mathsf{d}(S)\,y_\Sigma,\end{aligned}$$

which contradicts (10).

Proof of the claim. If $\Sigma=\mathrm{Ch}_0(S)$, every s with $\Theta(s)\neq0$ lies in $\mathrm{Fix}_S(\Sigma,\mathbf{d})$ by the hypothesis on the support, and the sum is 0. Otherwise fix $w\in\mathrm{Ch}_0(S)\setminus\Sigma$. Let $s\notin\mathrm{Fix}_S(\Sigma,\mathbf{d})$ with $\Theta(s)\neq0$. The first condition of Definition 2.2 holds for s, so the second fails: some leading minor of the frame Gram matrix of s_w, of an order $l\in\{0,\dots,\varrho+1\}$, vanishes. It therefore suffices to show, for each l,

$$\sum_{s:\ \text{the minor of order } l \text{ of } s_w \text{ vanishes}}\Theta(s)\;\le\;3\,b^{-10}\,\Theta_{\mathrm{tot}}, \tag{11}$$

since $3(\varrho+2)\,b^{-10} \le b^{-4}$.

Let F_0 be the matrix over $\mathbb{F}_w$ whose l columns are the frame vectors $\mathfrak{f}_0, \dots, \mathfrak{f}_{l-1}$, and $F_1 = JF_0$ with J the split Gram matrix of $T_S^{\mathrm{lat}}(\mathbb{F}_w)$; the minor of order l of s_w is $\det(F_1^t s_w F_0)$. We apply Input 7(b) to the group $\mathsf{G}(S)$, the homomorphism $s \mapsto s_w$, the field $\mathbb{F}_w$ of q_0 elements, the index sets $I(\mathfrak{s})$ (of $2\varrho+k+1$ elements) and $\{0,\dots,l-1\}$, the matrices F_0, F_1, and $Y = b^{-6k}\,\Theta_{\mathrm{tot}}$. Its hypothesis concerns, for a non-zero $v \in \mathbb{F}_w^l$, the sets of the s with $s_w F_0 v = F_0 v$, respectively $(s_w^{-1})^t F_1 v = F_1 v$; these are the groups $\mathrm{Fix}_{S,w}((\epsilon, v'))$ for ϵ false, respectively true, where v' is v extended by zeros. Fix such (ϵ, v') and put $\Theta' = \Theta \cdot \mathbf{1}_{\mathrm{Fix}_{S,w}((\epsilon,v'))}$. Then $\Theta' \ge 0$; $\Theta'(a^{-1}b) = \langle u'(a), u'(b)\rangle$ for the vectors $u'(a) = \delta_{a_w^{(\epsilon)} F_0 v} \otimes u(a)$ in the tensor product of the space of functions on $\mathbb{F}_w^{I(\mathfrak{s})}$ with V, where δ_x is the indicator of the point x; the sums of Θ' are dominated by those of Θ, hence by the energies; and $\Theta'(s) \ne 0$ implies $s \in \mathrm{Fix}_{S,w'}(\mathbf{d}'_{w'})$ for all $w' \in \Sigma \cup \{w\}$, where $\mathbf{d}'$ is $\mathbf{d}$ with the pair at w replaced by (ϵ, v'). The induction hypothesis for $\Sigma \cup \{w\}$ and (10) give

$$\sum_s \Theta'(s) \le (1 + 9b^{-4})\,\mathsf{d}(S)\,y_\Sigma\,b^{-6k} < b^{-6k}\,\Theta_{\mathrm{tot}} = Y.$$

So Input 7(b) applies:

$$q_0 \cdot \sum_{s:\ \det(F_1^t s_w F_0)=0} \Theta(s) \;\le\; 2\,\Theta_{\mathrm{tot}} + q_0^l \sqrt{q_0^{2\varrho+k+1}} \cdot b^{-6k}\,\Theta_{\mathrm{tot}}.$$

Since $q_0 \le b^{11}$ and $l \le \varrho+1$, the square of $q_0^l\sqrt{q_0^{2\varrho+k+1}}$ is at most $b^{11(4\varrho+k+3)} \le b^{12k}$, because $44\varrho + 33 \le k$; so the right side is at most $3\,\Theta_{\mathrm{tot}}$, and $q_0 \ge b^{10}$ gives (11). □

7 Terms in and off the Bessel subgroup

In this section $\mathcal{S} = \mathcal{S}(T_S^{\mathrm{rat}}(E))$, $\mathcal{U} = \mathcal{U}(T_S^{\mathrm{rat}}(E))$, and $\mathcal{S}^c$ is the complement of $\mathcal{S}$ in $G_S(E)$.

Lemma 7.1 (the trace of a small central idempotent on the Bessel terms)**.** *In Setting 2.1, suppose that E carries Weil data and that S is admissible. Let $i \in \{0,1\}$ and let $x \in \mathbb{C}[\mathsf{G}_i(S)]$ be a central idempotent with* $\mathrm{Re}\ x(1) \le b(S)^{-8}/2$*. Then*

$$\mathrm{Re} \sum_{s \in \mathsf{G}_i(S)} x(s) \sum_{(c,a) \in \mathrm{Cl}(S) \times \mathrm{Bc}(S)} \frac{A_S^{\mathrm{full}}(\mathcal{S}; c, \iota_i(s)^{-1}, c)_{(a,a)}}{\nu(S)} \;\le\; b(S)^{-4} \cdot \mathrm{cd}(S).$$

Proof. Let T be the set of all chosen places of S and their conjugates. It is stable under conjugation, and $\hat{g}(S)^{-1}$ is integral off T by Input 1(f), applied to the idempotent adele of the complement of T. Take a place structure and a filling level $\mathcal{L} \in \mathrm{FL}(S, \mathsf{T})$ (Input 4(a)); write K_1, K_g as in §4, $\chi = \chi_{g_{\mathcal{L}}}(\cdot)$, and for $s \in \mathsf{G}_i(S)$ choose $\sigma_s \in K(S)$ with $\mathrm{red}_S(\sigma_s) = \iota_i(s)$ (admissibility). Denote by $\mathcal{L}_0$ the sum on the left, before taking real parts.

Pointwise identity. For every $y \in K_1$,

$$\mathcal{L}_0 = \mathrm{cd}(S) \cdot \sum_s x(s)\,\chi(y\,\mathrm{loc}_{S,\mathsf{T}}(\sigma_s)\,y^{-1}). \tag{12}$$

Write $y = \mathrm{loc}_{S,\mathsf{T}}(\kappa_1)$ with $\kappa_1 \in K(S)$ (Input 4(b)). As x is a class function, we may replace s by its conjugate under the i-th component of $\mathrm{red}_S(\kappa_1)$; so it suffices to show, for $l = \kappa_1\sigma_s\kappa_1^{-1} \in K(S)$, that

$$\sum_{(c,a)} A_S^{\mathrm{full}}(\mathcal{S}; c, \mathrm{red}_S(l)^{-1}, c)_{(a,a)} = \mathrm{cd}(S)\,\nu(S)\,\chi(\mathrm{loc}_{S,\mathsf{T}}(l)).$$

Case 1: $\mathrm{loc}_{S,\mathsf{T}}(l) \in u' K_g$ with $u' \in \mathcal{U}$. Lift u' to an element κ' of $\mathcal{U}$, integral off T (Input 4(b)); it lies in $K(S)$, since $\mathrm{loc}_{S,\mathsf{T}}(\kappa') \in \mathrm{loc}_{S,\mathsf{T}}(l) K_g \subseteq K_1$, and $\mathrm{red}_S(\kappa') = \mathrm{red}_S(l)$. Then $\chi(\mathrm{loc}_{S,\mathsf{T}}(l)) = \psi_S^{\mathcal{U}}(\kappa')$ (Inputs 5(a) and 4(b)), and by the equivariance and the identity term (Input 2(c),(b)) $A_S^{\mathrm{full}}(\mathcal{S}; c, \mathrm{red}_S(\kappa')^{-1}, c) = \psi_S^{\mathcal{U}}(\kappa') \cdot A_S^{\mathrm{full}}(\mathcal{S}; c, 1, c)$, whose diagonal entries are $\psi_S^{\mathcal{U}}(\kappa')\,\nu(S)$. Summing over the $\mathrm{cd}(S)$ pairs (c, a) gives the identity.

Case 2: no such u' exists. Then $\chi(\mathrm{loc}_{S,\mathsf{T}}(l)) = 0$, and we show that no $\gamma \in \mathcal{S}$ is a term over $(c, \mathrm{red}_S(l)^{-1}, c)$, so that the amplitude sums are empty. Suppose γ is one, with position $x_0 = \mathrm{pos}_S(c, c; \gamma) \in K(S)$. Write $\gamma = u\,\delta$ with $u \in \mathcal{U}$ and δ in $\mathcal{H}$, a rational element of the unitary group of κ, and let $y' = y_c^{-1} \delta y_c$. Then $x_0 = \mathrm{pos}_S(c, c; u) \cdot \mathrm{pos}_S(c, c; \delta) = \mathrm{pos}_S(c, c; u) \cdot \mathrm{inc}_S(y')$ (Input 1(g)), with $\mathrm{pos}_S(c, c; u) \in \mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ (Input 1(e)). As $x_0 \in K(S)$, Input 1(g) gives $\mathrm{inc}_S(y') \in K(S)$. The element $\mathrm{red}_S(l)$ is trivial at the chosen places above the other prime $q_{i+1}(S)$ (indices modulo 2), because l is conjugate in $K(S)$ to σ_s, which reduces to $\iota_i(s)$; so the reduction $\mathrm{red}_S(l)^{-1}$ of x_0 is 1 at these places, and by Input 1(g) so is that of $\mathrm{inc}_S(y')$. By Input 1(f), y' is integral and reduces to 1 at these places, and by freeness (Input 1(d), with $n = \kappa$ and the index $i+1$) $\delta = 1$. Thus $x_0 \in \mathcal{U}$ and $\mathrm{red}_S(x_0^{-1}) = \mathrm{red}_S(l)$, whence $\mathrm{loc}_{S,\mathsf{T}}(l) \in \mathrm{loc}_{S,\mathsf{T}}(x_0^{-1}) K_g$: the excluded case.

Integration. Integrating (12) over K_1 for $\mathsf{M}(\mathcal{L})$, $\mathsf{M}(\mathcal{L})(K_1)\,\mathcal{L}_0 = \mathrm{cd}(S) \sum_s x(s)\, I_s$ with $I_s = \int_{K_1} \chi(y\, \mathrm{loc}_{S,\mathsf{T}}(\sigma_s)\, y^{-1})\, d\mathsf{M}(\mathcal{L})(y)$. By the Cauchy–Schwarz inequality $|\sum_s x(s) I_s|^2 \le \sum_s |x(s)|^2 \cdot \sum_s |I_s|^2$. For a central idempotent $x(s^{-1}) = \overline{x(s)}$ (Input 8(a)), so $\sum_s |x(s)|^2 = (x \cdot x)(1) = x(1) \le b(S)^{-8}/2$; here $x(1)$ is real and non-negative, being this sum. The cosets $\mathrm{loc}_{S,\mathsf{T}}(\sigma_s) K_g$ are pairwise disjoint (Input 4(b)), and on such a coset the inner integral of $\mathcal{J}_0(\mathcal{L}; K_1)$ is constant, equal to I_s, because K_1 normalises K_g and χ is right-invariant under K_g. Hence, by the bottom value with $t = 0$ (Input 5(b)),

$$\begin{aligned} \mathsf{M}(\mathcal{L})(K_g) \sum_s |I_s|^2 \;&\le\; \mathcal{J}_0(\mathcal{L}; K_1) \;\le\; \mathsf{M}(\mathcal{L})(K_1)\, \mathsf{M}(\mathcal{L})(K_g)\, \big(\mathsf{M}(\mathcal{L})(K_1) + 2^{-n(\mathfrak{s})}\big) \\ &\le\; 2\, \mathsf{M}(\mathcal{L})(K_1)^2\, \mathsf{M}(\mathcal{L})(K_g), \end{aligned}$$

where $2^{-n(\mathfrak{s})} \le \mathsf{M}(\mathcal{L})(K_1)$ by Input 5(c) and Lemma 4.1. Therefore

$$\mathsf{M}(\mathcal{L})(K_1)^2\, |\mathcal{L}_0|^2 \;\le\; \mathrm{cd}(S)^2 \cdot \tfrac{1}{2} b(S)^{-8} \cdot 2\, \mathsf{M}(\mathcal{L})(K_1)^2,$$

that is $|\mathcal{L}_0| \le b(S)^{-4} \mathrm{cd}(S)$. □

LEAN `Filling.re_trace_besselS_le`

Lemma 7.2 (second moment off the Bessel subgroup)**.** *In Setting 2.1, suppose that E is stably unramified and that S is admissible, and let $i \in \{0, 1\}$. Let Ω_i be the set of the $s \in \mathsf{G}(S)$ whose i-th component is that of an element of $\overline{\mathcal{S}}^S$. Then*

$$\mathrm{En}_S(A_S^{\mathrm{full}}(\mathcal{S}^c; \cdot, \cdot, \cdot); \Omega_i) \;\le\; b(S)^{-12} \cdot \mathsf{d}_1(S).$$

Proof. We apply Input 3 with $\Xi = \mathcal{S}^c$ (stable, Input 1(b)), $\Omega = \Omega_i$, $C = \mathsf{d}_1(S)$, $\omega_0 = 0$, $\mathcal{R} = \emptyset$ and $X = q_i(S)^{2f(E)}$; its conclusion is the claim. Write $b = b(S)$, $k = k(\mathfrak{s})$.

Every $s \in \Omega_i$ fixes norm at least X. Let $s_i = t_i$ with $t = \mathrm{red}_S(\kappa_1)$, $\kappa_1 \in \mathcal{S} \cap K(S)$. An element of the Bessel subgroup fixes the first frame vector $\mathfrak{f}_0$; so for every

$w \in \mathrm{Ch}_i(S)$ the reduction of κ_1 at w fixes $\mathfrak{f}_0$, and so does the reduction of its entrywise conjugate, which is the inverse adjoint of the former. Hence $s \in \mathrm{Fix}_{S,w}((\epsilon, e_0))$ for both Booleans ϵ, e_0 the first coordinate vector; these are $2f(E)$ triples.

No term is in normal form of index 0. Suppose $\gamma \in \mathcal{S}^c$ is a term over (c, s, c') with $s \in \Omega_i$ and is in normal form of index 0 with the scalar υ. For the frame index 0 this says $\gamma \mathfrak{f}_0 = \upsilon \mathfrak{f}_0$, so by Input 1(e) the $(\mathfrak{f}_0, \mathfrak{f}_0)$-entry of $\mathrm{pos}_S(c, c'; \gamma)$ is υ: it is integral, and it reduces at every $w \in \mathrm{Ch}_i(S)$ to the corresponding entry of $s_w = t_w$, which is 1. By freeness for the unitary group of rank one (Input 1(d)), $\upsilon = 1$. Then, by induction on the frame index a, $\gamma \mathfrak{f}_a - \mathfrak{f}_a$ lies in the span of the earlier frame vectors; so $\gamma \in \mathcal{S}$, a contradiction. Thus the condition on normal forms is void.

The remaining conditions. $\mathsf{d}_1(S) \le C$ holds with equality, and the link energy over the empty set of links is 0. As no link lies in $\mathcal{R}$, we need $\mathrm{tl}(S)^{12} X^{-k} \mathsf{d}(S) \le \mathsf{d}_1(S)$. By admissibility $\mathrm{tl}(S)^{18} \mathrm{cf}(S) \mathsf{d}(S) \le \mathsf{d}_1(S)$, where

$$\mathrm{tl}(S)^{18} \mathrm{cf}(S) = 2\,\mathrm{tl}(S)^{20} (b/g(S))^{kf(E)} \;\ge\; 2\,\mathrm{tl}(S)^{12}\, b^{3kf(E) - 23kf(E)},$$

using $\mathrm{tl}(S)^8 = b^{2kf(E)}$ and $g(S) \le b^{23}$; and $X^{-k} = q_i(S)^{-2kf(E)} \le b^{-20kf(E)}$. □

LEAN `Filling.energy_compl_besselS_le`

Lemma 7.3 (rows of the terms off the Bessel subgroup)**.** *In Setting 2.1, suppose that E is stably unramified and that S is admissible. Let $i \in \{0, 1\}$ and let $x \in \mathbb{C}[\mathsf{G}_i(S)]$ be a central idempotent. For $a = (a_1, a_2)$ and $b = (b_1, b_2)$ in $\mathrm{Cl}(S) \times \mathrm{Bc}(S)$ put*

$$\mathsf{m}_{ab} = \sum_{t \in \mathsf{G}_i(S)} x(t)\, \frac{A_S^{\mathrm{full}}(\mathcal{S}^c; a_1, \iota_i(t)^{-1}, b_1)_{(a_2, b_2)}}{\nu(S)}.$$

Then the sum of the ℓ^2-norms of the rows of this matrix satisfies

$$\sum_{a \in \mathrm{Cl}(S) \times \mathrm{Bc}(S)} \big\| (\mathsf{m}_{ab})_{b \in \mathrm{Cl}(S) \times \mathrm{Bc}(S)} \big\|_{\ell^2} \;\le\; b(S)^{-4} \cdot \mathrm{cd}(S).$$

Proof. For $\sigma \in \mathsf{G}(S)$ put $Y(\sigma) = \nu(S)^{-2} \sum_{c, c'} \big\| \sum_t x(t)\, A_S^{\mathrm{full}}(\mathcal{S}^c; c, \iota_i(t)^{-1}\sigma, c') \big\|^2$. The sum of the squares of the row norms in the statement is $Y(1)$.

$Y(\sigma) = Y(1)$ for $\sigma \in \overline{\mathcal{S}}^S$. For every class c' choose a class $p(c')$ and $\gamma_{c'} \in \mathcal{S} \cap \mathrm{Tm}_S(c', \sigma, p(c'))$ (Input 1(c)). The map p is injective, hence bijective: if $p(c') = p(d')$, then $\gamma_{c'} \gamma_{d'}^{-1} \in \mathcal{S}$ has its position over (c', d') in $K_g(S)$, so $c' = d'$ (Input 1(c)). Write $\gamma_{c'} = u\,\eta$ with $u \in \mathcal{U}$, $\eta \in \mathcal{H}$. By Input 2(e) the product Bessel function transforms under $\mathrm{r}_S^\infty(u)$ by a scalar of modulus 1 and under $\mathrm{r}_S^\infty(\eta)$ by a unitary operator; so the tensor $W(y) \otimes \overline{W(\gamma_{c'}\gamma^{-1} y)}$ is the image of $W(y) \otimes \overline{W(\gamma^{-1} y)}$ under a unitary operator $L_{c'}$ of $\ell^2(\mathrm{Bc}(S) \times \mathrm{Bc}(S))$, the identity in the first factor. By the moves (Input 2(d), with the trivial move on the left and $\gamma_{c'}$ on the right; $\mathcal{S}^c$ is preserved), $A_S^{\mathrm{full}}(\mathcal{S}^c; c, s\,\sigma^{-1}, c') = L_{c'}(A_S^{\mathrm{full}}(\mathcal{S}^c; c, s, p(c')))$ for all s. Taking $s = \iota_i(t)^{-1}\sigma$, summing against $x(t)$ and using that $L_{c'}$ is unitary and p bijective gives $Y(1) = Y(\sigma)$.

The sum over $\overline{\mathcal{S}}^S$. Fix c, c' and let $f(s) = A_S^{\mathrm{full}}(\mathcal{S}^c; c, s, c')$ for $s \in \Omega_{i+1}$ and $f(s) = 0$ otherwise, with Ω_{i+1} as in Lemma 7.2 (indices modulo 2). For $\sigma \in \overline{\mathcal{S}}^S$ and $t \in \mathsf{G}_i(S)$ the element $\iota_i(t)^{-1}\sigma$ lies in Ω_{i+1}. So by Input 8(a)

$$\sum_{\sigma \in \overline{\mathcal{S}}^S} \Big\| \sum_t x(t) f(\iota_i(t)^{-1}\sigma) \Big\|^2 \;\le\; \sum_{s \in \Omega_{i+1}} \|f(s)\|^2,$$

and summing over c, c', with Lemma 7.2,

$$\#\overline{\mathcal{S}}^{S}\cdot Y(1)=\sum_{\sigma\in\overline{\mathcal{S}}^{S}}Y(\sigma)\ \le\ \mathrm{En}_S(A_S^{\mathrm{full}}(\mathcal{S}^c;\cdot,\cdot,\cdot);\Omega_{i+1})\ \le\ b(S)^{-12}\,\#\overline{\mathcal{S}}^{S}\cdot\mathrm{cd}(S).$$

Hence $Y(1)\le b(S)^{-12}\mathrm{cd}(S)$, and by the Cauchy–Schwarz inequality over the $\mathrm{cd}(S)$ rows the sum of the row norms is at most $\sqrt{\mathrm{cd}(S)\cdot Y(1)}\le b(S)^{-6}\mathrm{cd}(S)\le b(S)^{-4}\mathrm{cd}(S)$. □

LEAN `Filling.sum_norm_amplitudeSum_le`

8 The variance argument: proof of Theorem B

Proof of Theorem B. Write $b=b(S)$, $\nu=\nu(S)$, $e=g_0\otimes g_1\in\mathbb{C}[\mathsf{G}(S)]$, $V_e=\rho(e)V$ and $A(s)_{xy}=A_S^{\mathrm{full}}(G_S(E);x_1,s,y_1)_{(x_2,y_2)}$ for $x,y\in\mathrm{Cl}(S)\times\mathrm{Bc}(S)$. By Input 8(a), e and the $1-g_i$ are central idempotents, and for a central idempotent z the operator $\rho(z)$ is a self-adjoint idempotent that commutes with all $\rho(s)$.

Normalisation. Let $t_0>0$ with $t_0^2=(c\,\nu)^{-1}$ and $\mathsf{P}=t_0Q$. By (i) and (ii),

$$\big\langle\rho(b')\mathsf{P}e_y,\ \rho(a')\mathsf{P}e_x\big\rangle=\frac{A(a'^{-1}b')_{xy}}{\nu}\qquad(a',b'\in\mathsf{G}(S)).\tag{13}$$

In particular the Gram matrix $(\langle\mathsf{P}e_y,\mathsf{P}e_x\rangle)_{x,y}$ minus the identity has the entries $A(1)_{xy}/\nu-\delta_{xy}$, which by the splitting and the identity term (Input 2(a),(b)) are $A_S^{\mathrm{full}}(\mathcal{S}^c;x_1,1,y_1)_{(x_2,y_2)}/\nu$. This matrix is hermitian and is, up to complex conjugation, that of $\mathsf{P}^*\mathsf{P}-1$; so by Lemma 7.3 for $i=0$ and the central idempotent 1, $\sum_x\|(\mathsf{P}^*\mathsf{P}-1)e_x\|\le b^{-4}\mathrm{cd}(S)$.

The variance inequality. Fix F and ϕ, and for $s\in\mathsf{G}(S)$ put $U_s=R_s^{-1}(F)$ and $\mathsf{P}_s=\rho(s)\mathsf{P}$. For $v\in U_s$, $\mathsf{P}_sv-\rho(1-e)\mathsf{P}_sv=\rho(e)\rho(s)\mathsf{P}v=t_0R_s(v)\in F$, and $\mathsf{P}_s^*\mathsf{P}_s=\mathsf{P}^*\mathsf{P}$. Input 7(c), for P_s, $\mathsf{R}=\rho(1-e)$, U_s and F, gives

$$\dim U_s-b^{-4}\mathrm{cd}(S)-\sum_x\|\rho(1-e)\mathsf{P}_se_x\|^2\ \le\ \mathrm{Re}\big\langle\mathrm{dy}_{\mathbf{b}}(\mathsf{P}_s),\mathrm{dy}_{\mathbf{b}}(\mathbf{a})\big\rangle,\tag{14}$$

where $\mathrm{dy}_{\mathbf{b}}(\mathsf{P}_s)$ is formed with the vectors P_se_x and $\mathbf{a}$ is an orthonormal basis of F.

The mean over s. By Input 7(c) and (13),

$$\big\langle\mathrm{dy}_{\mathbf{b}}(\mathsf{P}_{a'}),\mathrm{dy}_{\mathbf{b}}(\mathsf{P}_{b'})\big\rangle=\sum_{x,y}\frac{|A(a'^{-1}b')_{xy}|^2}{\nu^2}=\Theta(a'^{-1}b'),$$

where $\Theta(s)=\mathrm{En}_S(A_S^{\mathrm{full}}(G_S(E);\cdot,\cdot,\cdot);\{s\})$. So Θ is ≥0 and of positive type, its sums over subsets are energies, and Theorem C for $\Sigma=\emptyset$ gives $\sum_s\Theta(s)\le(1+9b^{-4})\mathsf{d}(S)$. By Input 7(a), $\|\sum_s\mathrm{dy}_{\mathbf{b}}(\mathsf{P}_s)\|^2=\#\mathsf{G}(S)\sum_s\Theta(s)$, and by (iv)

$$\|\,\mathrm{dy}_{\mathbf{b}}(\mathbf{a})\|^2=\dim F=\phi\dim V_e\ \le\ \phi\cdot\#\mathsf{G}(S)\ \deg(S)\ \mathrm{mass}(E,r(\mathfrak{s})).$$

With $\mathsf{d}(S)=\mathrm{cd}(S)^2/(\deg(S)\,\mathrm{mass}(E,r(\mathfrak{s})))$ and $4\alpha\beta\le(\alpha+\beta)^2$,

$$\begin{aligned}\sum_s\mathrm{Re}\big\langle\mathrm{dy}_{\mathbf{b}}(\mathsf{P}_s),\mathrm{dy}_{\mathbf{b}}(\mathbf{a})\big\rangle&\le\#\mathsf{G}(S)\cdot\mathrm{cd}(S)\sqrt{(1+9b^{-4})\,\phi}\\&\le\ \#\mathsf{G}(S)\cdot\frac{\mathrm{cd}(S)}{2}(1+9b^{-4}+\phi).\end{aligned}$$

Hence there is s for which the right side of (14) is at most $\frac{1}{2}\mathrm{cd}(S)(1+9b^{-4}+\phi)$.

The bad part. For every s, $\|\rho(1-e)\mathsf{P}_s e_x\|^2 = \langle \mathsf{P}e_x, \rho(1-e)\mathsf{P}e_x\rangle$. In $\mathbb{C}[\mathsf{G}(S)]$,

$$1-e = \iota_0(1-g_0)+\iota_1(1-g_1)-(1-g_0)\otimes(1-g_1),$$

where $\iota_i(z)$ is z at the factor i tensored with 1; and $\langle \mathsf{P}e_x, \rho((1-g_0)\otimes(1-g_1))\mathsf{P}e_x\rangle \geq 0$, the operator of the central idempotent $(1-g_0)\otimes(1-g_1)$ being a self-adjoint idempotent. So by (13)

$$\sum_x \|\rho(1-e)\mathsf{P}_s e_x\|^2 \;\leq\; \sum_i \mathrm{Re}\sum_{t\in\mathsf{G}_i(S)} (1-g_i)(t)\sum_x \frac{A(\iota_i(t)^{-1})_{xx}}{\nu}.$$

Split A into its parts over $\mathcal{S}$ and over $\mathcal{S}^c$ (Input 2(a)). The first contributes at most $b^{-4}\mathrm{cd}(S)$ by Lemma 7.1 and (iii); the second at most the sum of the row norms of Lemma 7.3, again $b^{-4}\mathrm{cd}(S)$. So the bad part is at most $4\,b^{-4}\mathrm{cd}(S)$.

Conclusion. For the s found above, $\dim U_s \leq \frac{1}{2}\mathrm{cd}(S)(1+9b^{-4}+\phi)+b^{-4}\mathrm{cd}(S)+4b^{-4}\mathrm{cd}(S) = (\frac{1+\phi}{2}+\frac{19}{2}b^{-4})\mathrm{cd}(S)$. □

9 The dimension of the rows and the filling theorem

Lemma 9.1 (positions of the row parameters)**.** *In Setting 2.5, let τ be an infinite place of $E(D)$ and ι an element of the row index set $I(D)$. With $l_D(\tau) = (2\,\varkappa_D(\tau, \mathrm{num}_D(\iota')))_{\iota'\in I(D)}$ the doubled row parameters, the number of the $\iota' \in I(D)$ with $l_D(\tau)_\iota < l_D(\tau)_{\iota'}$ is $\mathrm{num}_D(\iota)$.*

Proof. The row parameter $\varkappa_D(\tau,\cdot)$ is strictly decreasing (Input 9(f)), so $l_D(\tau)_\iota < l_D(\tau)_{\iota'}$ holds exactly if $\mathrm{num}_D(\iota') < \mathrm{num}_D(\iota)$; and num_D is a bijection from $I(D)$ to $\{0,\dots,r(D)-1\}$. □

LEAN `Data.decrPosition_paramW`

Proposition 9.2 (the rows are at most the expected number)**.** *In Setting 2.5:*

$$\dim_{\mathbb{C}} \mathrm{Row}(D) \;\leq\; \#\mathsf{G}(D)\cdot\deg(S(D))\cdot\mathrm{mass}(E(D), r(D)).$$

Proof. By Input 9(f), $\dim \mathrm{Row}(D)$ is the dimension of the good forms on the definite space $W_{m(D)}(D)$, which is at most that of all forms of principal level on it. The doubled row parameters have the gap $h(D)$, so they are a Harish-Chandra parameter in the sense of the unit on the rows, and through it the forms of principal level on $W_{m(D)}(D)$ are algebraic forms with values in the weight representation. As the class automorphism groups of the level are trivial, their dimension is the number of classes of the principal level $K_g(D)$ times the dimension of the weight representation (Input 8(f)). The number of classes is $[K_0 : K_g(D)]$ times the weighted number of classes of the maximal level K_0, that is $\#\mathsf{G}(D)\cdot\mathrm{mass}(E(D), r(D))$ (Inputs 8(f) and 9(f)). The weight representation is a tensor product over the infinite places, and the dimension of each factor is the formal degree of the discrete series of the parameter (Input 8(g)), which is the degree of the Bessel system of $S(D)$ at that place (Input 9(a)). So the dimension of the weight representation is $\deg(S(D))$. □

LEAN `Data.finrank_rows_le_mass`

Proof of Theorem A. Let $S = S(D)$, of shape $\mathfrak{s}$; it is admissible, $E(D)$ carries Weil data, $b(S) = b(D)$ and $r(\mathfrak{s}) = r(D)$ (Input 9(a)). We apply Theorem B to the space $V = \mathrm{Prin}(D, Y_0(D))$ with the Petersson product (it is finite-dimensional), to the representation $\rho = \mathrm{rep}_{D,Y_0(D)}$ of $\mathsf{G}(D) = \mathsf{G}(S)$, to $Q = \mathcal{P}_S^{\mathrm{fit}}$, to the idempotents g_0, g_1 of Input 9(c) and to the number $\mathrm{vol}(K_g)$ in the place of the constant c of Theorem B (the letter c stays the scalar of Theorem A). Its hypotheses hold: (i) right translation is unitary (Input 8(f)); (ii) is the Petersson unfolding (Input 9(b)); (iii) is Input 9(c); and (iv) holds because $\mathrm{vol}(K_g) > 0$ and, as $\rho(g_0 \otimes g_1)V = e_0(D)\,\mathrm{Prin}(D, Y_0(D)) = \mathrm{Row}(D)$, by Proposition 9.2. Theorem B gives: for every subspace F of $\mathrm{Row}(D)$, with $\phi = \dim F / \dim \mathrm{Row}(D)$, there is $s \in \mathsf{G}(D)$ with

$$\dim R_s^{-1}(F) \;\le\; \Big(\frac{1+\phi}{2} + \frac{19}{2}\,b(D)^{-4}\Big)\mathrm{cd}(S), \qquad R_s = e_0(D) \circ \rho(s) \circ \mathcal{P}_S^{\mathrm{fit}}.$$

The column coordinates cc_D are a linear isomorphism from $\mathrm{Col}(D)$ onto the space $\ell^2(\mathrm{Cl}(S) \times \mathrm{Bc}(S))$; so $\dim \mathrm{Col}(D) = \mathrm{cd}(S)$, and by Definition 2.6 the map

$$R'_s = R_s \circ \mathrm{cc}_D = e_0(D) \circ \rho(s) \circ \mathcal{P}_D^{\circ}(\cdot)$$

satisfies the same bound with $\dim \mathrm{Col}(D)$ on the right. Now $B_s = \#\mathsf{G}(D) \cdot c \cdot R'_s \circ \mathrm{Ram}_D(\mathrm{Div}_N(D))$, and the non-zero scalars do not change preimages of subspaces: $B_s^{-1}(F) = \mathrm{Ram}_D(\mathrm{Div}_N(D))^{-1}(R_s'^{-1}(F))$. By Input 9(d), with $\#\mathrm{Div}_N(D) = f(E(D))$,

$$\begin{aligned}\dim B_s^{-1}(F) \;&\le\; \dim R_s'^{-1}(F) + \frac{f(E(D))}{N(D)-1}\dim \mathrm{Col}(D)\\ &\le\; \Big(\frac{1+\phi}{2} + \frac{19}{2}\,b(D)^{-4} + \frac{f(E(D))}{N(D)-1}\Big)\dim \mathrm{Col}(D),\end{aligned}$$

and the sizes of the data (Input 9(e), with $N(D) - 1 \ge b(D)^9$) bound the bracket by $\frac{1+\phi}{2} + b(D)^{-2}$. □

Proof of Corollary 1.1. Suppose $\dim \mathrm{Row}(D) = 0$. Theorem A for $c = 1$ and $F = \mathrm{Row}(D)$, for which $\phi = 0$ by the convention on the quotient, gives s with

$$\dim \mathrm{Col}(D) = \dim B_s^{-1}(\mathrm{Row}(D)) \le (\tfrac{1}{2} + b(D)^{-2})\dim \mathrm{Col}(D).$$

But $\mathrm{Col}(D) \neq 0$, being isomorphic to $\ell^2(\mathrm{Cl}(S(D)) \times \mathrm{Bc}(S(D)))$ with non-empty index sets, and $b(D)^{-2} < \frac{1}{2}$ (Input 9(e)): a contradiction. □

10 Where the results are used

Theorem A and Corollary 1.1 are used in the unit on the endgame: with the lemma on few translates of the unit on heights (a family that is spread with defect η has a subfamily of at most $5 \dim Y \log(1+\eta^{-1})/\dim X$ members whose images span a subspace of dimension at least $(1-4\eta)\dim Y$), applied with $\eta = b(D)^{-2}$ and with the constant of the seesaw identity for c, they give Theorem B of the handout's overview (enough forms). Corollary 1.1 is used twice more: in the main module of the proof, for the positivity of the dimension of the rows, and in the unit on the rows, in the module on the comparison of forms. Definition 2.6 is used in the unit on the seesaw (the seesaw theorem) and in the endgame, in the map $\mathcal{P}_D(\gamma)$ of the overview (§1). Proposition 9.2 is used only in the proof of Theorem A. Lemma 9.1 is not used in

the chain of this chapter: its only use is in the unit on the Selmer groups, in the module that shows that rows exist; it stands in §9 because the formal text has it in the module on the dimension of the rows. The module on link pairings, the fourth module of this chunk of the dossier, feeds the crude estimate (Input 3) and is the subject of Note P.

11 Notes on the formal text

1. *Theorem A.* The formal statement is the predicate "spread with defect $(b(D)^2)^{-1}$" of the unit on heights, applied to the family $s \mapsto \Pi_D(s) \circ \mathcal{P}^\circ_D(\cdot) \circ (c \cdot \mathrm{Ram}_D(\mathrm{Div}_N(D)))$. The domain is the space of all columns, not that of the ramified columns; the argument of the ramifying operator is the set of all primes dividing $\pi_N(D)$. The quotient $\dim F / \dim \mathrm{Row}(D)$ is Lean's division, which is 0 when the denominator is 0; the corollary uses exactly this case. The second reader confirmed the statement and the order of its quantifiers independently.
2. *Arguments that the census reads differently from Lean; to be settled by* `#check` *on a build.* The census lists for the Poincaré map a second explicit argument, which is the domain in the type of the linear map; the notation $\mathcal{P}^\circ_D(\psi)$ shows it as the column to which the map is applied. Proposition 4.6 takes the side as an implicit argument, which the census omits; it is stated here as the side σ, and the proof of Theorem D uses it for the cut side. Its explicit argument j_0, an element of the index set, serves only to know that the matrix R is a Gram matrix. In Proposition 4.7 the place structure is an implicit argument and not an instance.
3. *Statements cut by the census.* The statements of Lemma 4.2, Proposition 4.3, Proposition 4.5 and Proposition 4.6 contain local definitions, at which the census ends the statement; they were read to their true end in the source, with the second reader's table of corrected spans.
4. *Small sets.* "There is a neighbourhood of 0 such that for every set L contained in it" renders the formal "for all L eventually in the filter of small sets at 0".
5. *Sides.* In Theorems B, C and D and in the lemmas of §7 the amplitude sums are those of the full Bessel functions: the formal text names no side there and Lean takes its default instance. The link energy in the hypothesis of the crude estimate (Input 3) is that of the cut side, by a local instance of the file that proves it.
6. *Exponents computed here.* The following were computed from the Lean text and not taken from the dossier. (a) In Lemma 4.2: $6k \le 9(k - 10^{10}n^4)$ and $k - 10^{10}n^4 + 1 < 2\varrho + k + 1$. (b) In the proof of Theorem C the matrix of the frame vectors has l columns, for an order $l \le \varrho + 1$, the bound needed is $q_0^{2l+2\varrho+k+1} \le b^{12k}$, which follows from $44\varrho + 33 \le k$, and each order contributes at most $3b^{-10}$ of the total; the dossier's steps 13 to 15 of this proof state other exponents ($l + 1$ columns, a bound $1/b^{10}$ for the second term, and an inequality with $6k$), which the formal text does not need. (c) In Proposition 4.5 the ideal zeta function is taken at $3\varrho + 5$, with the conditions $[E : \mathbb{Q}] \le 2^{2\varrho}$ and $6\varrho + 12 \le k$; the dossier's steps 1.25.3 and 1.25.4 name $\varrho + 1$ and $2(\varrho + 2) \le k$. (d) In the proof of Theorem D the factors $(1 + b^{-4})^3 + b^{-12} \le (1 - b^{-4})(1 + 9b^{-4})$ and the final factor $\le 1 + b^{-4}$ were recomputed, and so was the identity $\rho_t(p)\mathsf{h}_\varrho(\mathcal{L}; \omega_p, 1) = r\sqrt{G}$ of Step 4, which the formal text verifies by expanding both sides; the computation is in the proof.

7. *The defect of Theorem B.* $\frac{19}{2} = \frac{9}{2} + 1 + 4$: $\frac{9}{2}$ from the constant $1 + 9b^{-4}$ of the second moment, 1 from the defect of orthonormality of the Poincaré series, 4 from the two bad parts.
8. *Inputs and their owners.* Input 4(c) is stated with the formal hypothesis, invariance of the measure under the images of all elements of the subgroup; the proof in Note G uses it only for integral elements, and the one application here, to $\mathcal{H}$ and $\theta_n(\mathcal{L})$, satisfies the formal hypothesis. Input 5 holds only what Note T proves; the facts about standard levels and about the tower method that the proofs of §4 use as well are Input 10, with the notes that own them. The inequality at the end of Input 10(d) is not a formal statement: it is a step of the formal proof of Proposition 4.7.
9. *The threshold of a fixing condition.* In "s fixes norm at least X" the number X is a natural number in the formal text, compared with a product of primes.
10. *Hypotheses.* Lemma 4.1 does not assume admissibility (the formal text omits it there). Lemmas 7.2 and 7.3 assume that E is stably unramified, the other results of §§5–8 that it carries Weil data. Lemma 7.1 takes the filling data as an explicit argument; the others take them implicitly.

How this note was written. From the structured proofs of the fourth chunk of the unit's dossier, which a second reader had re-read completely. I read in the Lean text, line by line, the five modules treated here (the filling theorem, the dimension of the rows, the moments, the fixed lines, the finite system) and the set-up module with the record of the filling data and its standing hypotheses, and compared every statement of this note with them argument by argument. Of the inputs, I read in the Lean text the statements of the crude estimate, of the fixing sets and energies, of sieve systems and the sieve, of the band limits, of the declarations of Notes G and T that are cited (with the corrected spans), of the variance lemmas of the unit on heights, of the central idempotents, and of the lemmas on the ramifying operator, the number of primes dividing $\pi_N(D)$ and the monotonicity of the row parameters; the other inputs are stated from the dossier's readings of the quoted statements. In the revision after the referee's report I read in the Lean text also the statements behind Inputs 1(g), 2(e), 4(c), 8(a), 8(c), 8(h) and 10, and the lattice basis. The proofs follow the formal ones. Shorter here: the support of the step function in Lemma 4.4; the limiting arguments of Proposition 4.5 and of Step 2 of the proof of Theorem D, which are described and not written out. The identity of hypothesis (e) in Step 4 of that proof is computed in the text; the computation is the referee's and was checked again. Nothing was compiled for this note. The program check of the unit's dossier covered 1371 leaf steps of 179 proofs.

Appendix A. Concordance with the Lean artifact

The formal names of the objects and the letters of this note: `S` is S, `𝔰` is $\mathfrak{s}$, `T` (a set of places) is T, `T` (a set of rational elements) is Ξ, `F` (a level) is $\mathcal{L}$, `Sg` and `A` (sets of chosen places) are Σ, `d` and `D` (frame-vector data) are $\mathbf{d}$, `v` (an infinite place) is τ, `Φ v x` is x_τ, `GRes` is $\mathsf{G}(S)$, `Data.G` is $\mathsf{G}(D)$, `besselS`, `besselU`, `besselH`, `GT ϱ` are $\mathcal{S}$, $\mathcal{U}$, $\mathcal{H}$, $\mathcal{H}_\varrho$, `unipCovolume` is $\nu(S)$, `mainEnergy` and `besselEnergy` are $\mathsf{d}(S)$ and $\mathsf{d}_1(S)$, `tailScale` is $\mathrm{tl}(S)$, `columnDim` is $\mathrm{cd}(S)$. Notation

P, D the parameters (N_0, d) and admissible data for them; $E(D)$, $m(D)$, $r(D)$, $k(D)$, $b(D)$, $N(D)$, $\pi_N(D)$, $h(D)$, $I(D)$, num_D, $\varkappa_D$, $K_g(D)$, K_0, $W_{m(D)}(D)$ as in Setting 2.5; $l_D(\tau)$ in Lemma 9.1

E, τ, x_τ a CM field with its CM type; an infinite place; the image of x at τ

$f(E)$, d_E, $\mathbb{Q}$ the number of infinite places; the discriminant; the rational numbers

w, $\bar{w}$, $\mathbb{F}_w$, E_w a finite place, its conjugate, residue field, completion

$\mathbb{A}_{E,f}$, $\hat{O}_E$, ψ_f finite adeles, integral adeles, the standard additive character

$\mathfrak{s} = (\varrho, \kappa, k_0)$ a shape; $\varrho(\mathfrak{s})$, $k(\mathfrak{s})$, $n(\mathfrak{s})$, $r(\mathfrak{s})$, $I(\mathfrak{s})$, $M(\mathfrak{s})$; in proofs k, n, ϱ abbreviate them where this is said

e_a, e_a^*, z, $\mathfrak{f}_a$ the hyperbolic basis vectors, the last basis vector, the frame

S filling data: $b(S)$, $N(S)$, $q_i(S)$, $g(S)$, $\bar{\pi}(S)$ (an idele; the bar belongs to the name), $\varpi(S)$, $\mathrm{Ch}_i(S)$, $K^{\mathrm{col}}(S)$, $\mathfrak{B}_\tau(S)$; $S(D)$ those of D; $\kappa_\tau(S)$ the real part of $g(S)\varpi(S)_\tau/(2\pi i)$

T, $J(T)$, $G(T)$, h_T, $Z_T(g)$ an $\mathfrak{s}$-form, its split Gram matrix, unitary group, hermitian form, frame Gram matrix; J a split Gram matrix; R a commutative ring in §2

$\mathcal{U}$, $\mathcal{H}$, $\mathcal{S}$, $\mathcal{H}_\varrho$ Bessel unipotent group, $\mathrm{U}(X_0)$, Bessel subgroup, the subgroup fixing all e_a, e_a^*;

$\mathrm{sd}(u)$ the sum of the superdiagonal; $\mathcal{S}^c$ the complement

$w_\varrho(p)$, $(p\,|\,t)$ Weyl element of length $\varrho(\mathfrak{s})$; the sequence $p_0, \dots, t, 1, \dots$

$T_S^{\mathrm{rat}}(R)$, $T_S^{\mathrm{lat}}(R)$, $G_S(R)$, G_S^{lat} the middle form in the standard and the lattice basis; the unitary groups; $\Lambda(S)$ the change of basis; x_{k_0} the basis vector of k_0

r_S^f, r_S^∞, inc_S the maps to the finite adelic group, to the real groups $G_1(\mathfrak{s})$, and of $\mathrm{U}(\kappa)$ into G_S^{lat}

$K(S)$, red_S, $K_g(S)$, $\overline{B}^S$ integral subgroup, reduction, principal level, reduced image of a subgroup B

$\mathsf{G}(S)$, $\mathsf{G}_i(S)$, ι_i; $\mathsf{G}(D)$ the finite groups of the chosen places and the inclusions of the factors

$\mathrm{Cl}(S)$, c, c', y_c, $h_S(c)$ classes, their representatives and images

$\mathrm{pos}_S(c, c'; \gamma)$, $\mathrm{Tm}_S(c, s, c')$ position of a rational element; terms over (c, s, c')

$Z_S(\gamma)$, $\mathfrak{g}_S(\gamma)$, $\mathrm{link}(\gamma)$, Λ frame Gram matrix, term discriminant, link; a link

$\mathrm{Bc}(S)$, $W_S^\sigma(y)_i$, σ Bessel coordinates, product Bessel function, a side (full or cut)

$a_S^\sigma(c, c'; \gamma)$, $A_S^\sigma(\Xi; c, s, c')$ amplitude, amplitude sum over a set Ξ; $\beta_{S,c}$ the cutoffs; $\mathcal{U}_{S,c}$; Bl a block

$\mathrm{En}_S(A; \Omega)$ energy of a family A over $\Omega \subseteq \mathsf{G}(S)$; Ω_i in Lemma 7.2

$\nu(S)$, $\mathrm{cd}(S)$, $\deg(S)$, $\mathrm{mass}(E, r)$ covolume, number of column coordinates, product of degrees, mass

$\mathsf{d}(S)$, $\mathsf{d}_1(S)$, $\mathrm{tl}(S)$, $\mathrm{cf}(S)$ main energy, Bessel energy, tail scale, codimension factor

$c_*(S)$, $a_*(S)$, $\mathrm{uo}(S)$, $\mathrm{fs}_S(\tau, a)$, $\mathrm{fs}(S)$, $\mathrm{oc}(\mathfrak{s})$ Siegel's constant, packet constant, unipotent order, frame scales and their product, the constant of the open cell

$\hat{g}(S)$, $\psi_S^{\mathcal{U}}(u)$ the idele of $g(S)$; the unipotent character

$\mathbf{d}$, $\mathrm{Fix}_{S,w}((\epsilon, v))$, $\mathrm{Fix}_S(\Sigma, \mathbf{d})$ frame-vector data, fixers, fixing sets; Σ a set of chosen places above $q_0(S)$; X a norm; y_Σ

T, T_0, E_T, O_T, ψ_T, mod_T a finite set of finite places, a finite set of places or of units, the product of completions with its integers, character and modulus; A, O_A, ψ_A, ν_A, δ_A for a general semilocal field

$\mathrm{loc}_{S,\mathsf{T}}$, $K_{S,\mathsf{T}}(u)$, K_1, K_g components at T; congruence groups

$\mathcal{L}$, $g_\mathcal{L}$, $\mathrm{FL}(S, \mathsf{T})$ a level, its unit, filling levels; $\mathsf{M}(\mathcal{L})$, $\theta_n(\mathcal{L})$, $\mu_{\varrho,2}^{\mathcal{L}}$, the quadric measure $\delta^{(\varrho)}(\mathcal{L})$, $\mathsf{M}_{\geq 0}(\mathcal{L})$ its measures; $\mathsf{A}(\mathcal{L}; W, x)$ the average of Input 10(d)

$\chi_g(y)$, $\mathrm{Int}(\mathcal{L})$, Z, $\mathrm{Cos}(Z)$, a_c finite Bessel function, intermediate groups, cosets and representatives

$\mathsf{v}(\mathcal{L})$, $\mathrm{mr}(Z)$, $\mathcal{J}_0(\mathcal{L}; Z)$, $W_Z(y)$ unipotent mass, mass ratio, bottom form, finite Bessel vector

$\mathrm{J}(\mu, W; \gamma)$, $\mathcal{J}(Z; p, l)$, $\mathcal{K}(L; Z; p, q)$, $\mathcal{E}(Z; R, \omega, e)$ correlation tensors, top kernel, local energy

$\mathsf{h}_j(\mathcal{L}; p, q)$, $\mathcal{J}_j(\mathcal{L}; p, q; W, \omega)$, $\Lambda_K(j; p)$ head density, floor form, head weights; $[\xi]$, $\mathrm{den}(\xi)$ generalised and denominator index

$a_{S,\mathsf{T}}^\sigma(c, s, c'; \gamma)$, $\psi_{S,\mathsf{T}}$, $\beta_{S,\mathsf{T}}(\xi)$ coset amplitude, character at T, frequency gain

J_L, J', $\mathcal{E}_0$, $u(c)$, ι_U, β, C, U kernels and data of a sieve system

$\mathrm{tv}(\pi, t, x)$, bl_τ, nc_τ, I_τ tail vector, band limit, normalised correlation, index set of a Bessel system

$\mathrm{Col}(D)$, $\mathrm{Row}(D)$, $\mathrm{Prin}(D, \mathcal{V})$, $\mathrm{rep}_{D,\mathcal{V}}$, $Y_0(D)$, $e_0(D)$ columns, rows, forms of principal level, their representation, the space of the rows, the good idempotent

$\mathcal{P}_D^\circ(\psi)$, $\Pi_D(s)$, $\mathrm{Ram}_D(\mathcal{W})$, $\mathrm{Div}_N(D)$, $\epsilon_D(w)$, cc_D Poincaré series map, translate and project, ramifying operator, primes dividing $\pi_N(D)$, central elements, column coordinates; $\mathcal{P}^{\mathrm{fit}}$ the Poincaré map of the set-up; $\mathcal{P}_D(\gamma)$ the map of the overview, c_0 the constant of the seesaw identity

$\mathrm{Spread}((B_s)_s; \eta)$, F, ϕ, η spread with defect η; a subspace; its share

V, ρ, Q, g_i, e, V_e, R_s, B_s, U_s the data of Theorem B and the maps of Theorems A, B; $\ell^2(\cdot)$ the Hilbert space of functions on a finite set, e_x its standard basis

Θ, u, Θ_{tot}, Y a function of positive type, its vectors, its total, a bound

P, R, $\mathrm{dy}_\mathbf{b}$, $\mathbf{a}$, $\mathbf{b}$, t_0, ε operators, the dyad sum, orthonormal bases, a normalisation, a small number

G, H; G in §§4, 5 a finite group and an inner product space in Input 7; the number $(\prod_\tau(|t_\tau|^2 - N(S)^2))^{k(\mathfrak{s})-1}$

$\mathcal{Y}$, wt, f, L, M, Ψ, Φ, Φ_0, $\mathfrak{F}$ pairs, weights, a function, a small set, an integer, step and test functions, the Fourier integral of Proposition 4.5; β, α, v_0, w_0, r_0, a, c', b, B_0, M_0, $\mathcal{D}(\tau')$, $\pi_\mathsf{T} = \bar{\pi}(S)_\mathsf{T}$ there; $\mathfrak{c}_M$, m, a_0, n' in Input 8(c)

$\mathcal{J}$, $\mathcal{F}$, j, j_0, γ_j, k_j, l_j, t, R, ρ, r, ω_p, y_j, $\gamma_{j,p}$ the data of Proposition 4.6 and of the proof of Theorem D; m_{ab} the matrix of Lemma 7.3; D_0, g, Θ_0, θ, v_θ, n_θ, z_0, e_0 in its proof

o, c_o, H, $\mathfrak{p}$, φ, λ, $Q(Z')$ in §4: none or a place, a constant, a subgroup, maps, the constant of the Haar measure, a product subgroup

x, i, q, p, m, l, s, b, k, n, h, d, N, K, X, I, O, W, A elements, indices, sequences, the usual meanings as stated where they occur; $\mathbb{C}$, $\mathbb{R}$; υ a scalar of norm one; $\zeta_{\hat{O}_E}$ the ideal zeta function; π the number; A_η the operator of Input 2(e); δ, ϵ, κ_0, κ_1, κ', σ_s, ϖ_w, ξ, ν, μ, ψ, χ, ω, ω_0, Γ, Ω, Λ as introduced

READBACK NOTE 37

The top floor at a finite place: finite Bessel functions, shell bounds and the top kernel

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. At finitely many finite places the second moment of the Poincaré series is governed by one function on a unitary group over a product A of local fields: the *finite Bessel function*, which is a character of the Bessel unipotent subgroup on the cosets of a principal congruence subgroup and zero elsewhere. This note feeds the vector of its translates, the *finite Bessel vector* of a group Z between the congruence subgroup and the integral group, into the tower method of the unit on the real place. It proves three things. The floor forms of this vector decay in the frequency: a non-integral frequency ξ costs a power of the index of ξ. The form at the bottom of the tower is the square of the measure of Z up to an error that is a high power of the volume of the non-units. And at the top floor the form unfolds to an integral of inner products of *correlations*, which gives a kernel that is continuous, of positive type, and bounds from above an energy that counts packets of rational terms. The estimates rest on one *shell bound*: the positions are sorted by the denominator ideal of $(x-1)/g$, and a sum over ideals is paid for by an ideal zeta function.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, of the Riemann hypothesis and of its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles and that Lean's kernel accepted the proofs; an independent replay is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note (Note T of its unit) treats 45 of the 497 declarations of the unit *Translates of Poincaré series fill the rows*: the module on the top floor at a finite place. Proved here from the inputs: Theorems A to D and the statements of §§4–6. Taken for granted and stated as Inputs 1 to 5 in §3: the Bessel subgroup and the congruence subgroups from the background library, the tower of floor measures and its estimates from the unit on the real place, the standard levels from another note of this unit, and three facts on ideals, valuations and Eichler elements. Every statement was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 45 declarations.

1 The statements

The objects are defined in §2. In brief: A is a finite product of local fields with an involution, T a hermitian form of a shape $\mathfrak{s}$, $G(T)$ the unitary group of its split Gram matrix, $\mathcal{L}$ a standard level with unit $g_{\mathcal{L}}$ and congruence subgroup $\mathrm{K}^\circ(\mathcal{L})$, and Z a group between $\mathrm{K}^\circ(\mathcal{L})$ and the group $K_T(1)$ of the integral isometries. The finite Bessel vector $W_Z(y)$ has one coordinate for each coset of $\mathrm{K}^\circ(\mathcal{L})$ in Z; $\mathcal{I}_j(\mathcal{L};p,q;W,\omega)$ is the floor form of the unit on the real place, $\mathrm{mr}(Z)$ the mass ratio, $[\xi]$ the generalised index and $\mathrm{den}(\xi)$ the denominator index of a unit ξ.

Theorem A (the frequency bound). *In Setting 2.4, let $j \le \varrho(\mathfrak{s})$, let K and t be natural numbers with $10^{10}n(\mathfrak{s})^4 \le K$ and $t + 10^{10}n(\mathfrak{s})^4 \le k(\mathfrak{s})$, let ξ be a unit of A, let p, q be sequences of units of A, and let $\omega\colon G(T) \to \mathbb{C}$ be a function such that either $\omega(x) = \psi_A(\xi \cdot Z_T(x)_{jj})$ for all x, or there is i with $j = i+1$, $\omega = 1$ and $\xi = g_{\mathcal{L}}^{-1}(p_i^{-1} - q_i^{-1})$. Then*

$$\left|\mathcal{I}_j(\mathcal{L};p,q;W_Z(\cdot),\omega)\right| \;\le\; \mathrm{mr}(Z)\cdot[\xi]^{t/2}\,\mathrm{den}(\xi)^{-6}\left(\frac{2}{\mathrm{mod}_A(g_{\mathcal{L}})}\right)^{K}\Lambda_K(j;p)\,\Lambda_K(j;q).$$

LEAN `IntegralPlace.IsStdLevel.enorm_floorForm_le`

Theorem B (the bottom value). *In Setting 2.4, let t be a natural number with $t + 10^{10}n(\mathfrak{s})^4 \le k(\mathfrak{s})$. Then*

$$\mathcal{I}_0(\mathcal{L};Z) \;\le\; \mathsf{M}(\mathcal{L})(Z)\cdot\mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L}))\cdot\Big(\mathsf{M}(\mathcal{L})(Z) + \mathrm{vol}(O_A\setminus O_A^\times)^{t+1}\cdot 2^{-n(\mathfrak{s})}\Big).$$

LEAN `IntegralPlace.IsStdLevel.floorZeroForm_le_main_term`

Theorem C (the top floor: unfolding and continuity). *In Setting 2.4:*

(i) *Let p, q be sequences of units of A and $\xi \in A$; put $\varphi_\xi(x) = \psi_A(\xi \cdot Z_T(x)_{\varrho\varrho})$ for $x \in G(T)$. Then the function $F_\xi(l) = \varphi_\xi(l^{-1})\cdot\langle \mathcal{J}(Z;p,l), \mathcal{J}(Z;q,l)\rangle$ is integrable for the measure $\mu^{\mathcal{L}}_{\varrho,2}$, and*

$$\mathcal{I}_\varrho(\mathcal{L};p,q;W_Z(\cdot),\varphi_\xi) \;=\; \int F_\xi(l)\,d\mu^{\mathcal{L}}_{\varrho,2}(l).$$

(ii) *Let L be an open additive subgroup of A. Then $(p,q) \mapsto \mathcal{K}(L;Z;p,q)$ is a continuous function on the pairs of sequences of units of A.*

LEAN `IntegralPlace.IsStdLevel.floorForm_top_eq_integral` · `IntegralPlace.IsStdLevel.continuous_topKernel`

Theorem D (the top floor: energy and packets). *In Setting 2.4, let $\mathcal{C}$ be a finite set, R a complex matrix with rows and columns indexed by $\mathcal{C}$, and $\omega = (\omega_i)_{i\in\mathcal{C}}$ a family of sequences of units of A.*

(i) *Let $L \subseteq A$ be an open subset, suppose that R is positive semidefinite, and let t be a unit of A with $(\omega_i)_\varrho = t$ for all indices $i \in \mathcal{C}$. Then $\mathcal{Q} = \sum_{i,i'\in\mathcal{C}} R_{ii'} \cdot \mathcal{K}(L; Z; \omega_i, \omega_{i'})$ is real and $\mathcal{Q} \geq 0$, and*

$$\int \mathbf{1}\big[(J(T)\,e)_z - t \in L\big] \cdot \mathcal{E}(Z; R, \omega, e)\; d\delta^{(\varrho)}(\mathcal{L})(e) \;\leq\; \mathcal{Q}.$$

(ii) *Suppose that the units of A form an open set and that inversion is continuous at 1. Let e be a vector, Θ_0 a non-empty finite set, and for $\theta \in \Theta_0$ let $l_\theta \in \mathcal{H}_\varrho(T)$ with $l_\theta^{-1} z = e$ and $n_\theta \in \mathrm{Cos}(Z) \times \mathrm{Cos}(Z)$, such that $l_\theta l_{\theta'}^{-1} \in \mathrm{K}^\circ(\mathcal{L})$ and $n_\theta = n_{\theta'}$ together imply $\theta = \theta'$. For $\theta \in \Theta_0$ let v_θ be the vector with the coordinate $\mathcal{J}(Z; \omega_i, l_\theta)_{n_\theta}$ for every index $i \in \mathcal{C}$. Then there is a neighbourhood of e such that for every x in it, every $k \in \mathcal{H}(T) \cap \mathrm{K}^\circ(\mathcal{L})$ and every vector y with $k\,y = x$,*

$$\theta_n(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L})) \cdot \sum_{\theta\in\Theta_0} \big(\mathrm{Re}\; v_\theta^* R v_\theta\big)^+ \;\leq\; \mathcal{E}(Z; R, \omega, y).$$

LEAN `IntegralPlace.IsStdLevel.lintegral_energy_le_topKernel` · `IntegralPlace.IsStdLevel.eventually_sum_packets_le_energy`

Theorem A is the decay of the finite sieve in the frequency, Theorem B its bottom value, and Theorems C and D are what the top floor of the sieve needs: the last form is an integral of a positive kernel, and that kernel dominates the sum over the packets of rational terms that the main note of the unit (Note F, *Translates of Poincaré series fill the rows*) compares with Siegel's formula.

2 The setting

Conventions. The natural numbers are $0, 1, 2, \ldots$, and a difference of natural numbers is read as 0 when it would be negative. A is a *semilocal field*: a locally compact topological ring with a Haar measure vol and a compact open subring O_A of volume 1, in this proof always a finite product of non-archimedean local fields. It carries an involution $x \mapsto \bar{x}$ and an *integral place structure*: O_A is stable under the involution; $O_A^\times$ is the group of the units of O_A; ψ_A is a unitary additive character of A which is *self-dual*, that is, $\psi_A(ra) = 1$ for all $r \in O_A$ exactly if $a \in O_A$; for a unit u of A, $\mathrm{mod}_A(u)$ is the modulus, $\mathrm{vol}(uX) = \mathrm{mod}_A(u)\,\mathrm{vol}(X)$, and $[u] = \mathrm{mod}_A(u)^{-1}$ is the *generalised index*, which for $u \in O_A$ is the index of uO_A in O_A, so that then $[u] \geq 1$; for a unit ξ, $\mathrm{den}(\xi)$ is the index of $O_A \cap \xi^{-1} O_A$ in O_A. The place structure has further data (a trace-one element, a measure on the skew elements) that enter only through the inputs; its Plancherel constant is 1. A *shape* is a triple $\mathfrak{s} = (\varrho, \kappa, k_0)$ of a natural number, a finite set and an element of it; $\varrho(\mathfrak{s}) = \varrho$, $k(\mathfrak{s}) = \#\kappa$, $n(\mathfrak{s}) = \varrho(\mathfrak{s}) + 1$. T is an *$\mathfrak{s}$-form* over A whose split Gram matrix is a *hermitian unit* (hermitian and invertible); ι is a finite set, m a natural number, and $\mathcal{L}$ denotes a level of T in $\mathrm{Lev}(\iota, T, m+1)$, in the sense recalled below. A *sequence*

of units is a map $p\colon \mathbb{N} \to A^\times$, $a \mapsto p_a$; the sequences of units carry the product topology, and 1 is the constant sequence. For a finite set X, $\ell^2(X)$ is $\mathbb{C}^X$ with the inner product $\langle v, w\rangle = \sum_x \bar{v}_x w_x$, conjugate-linear in the first variable; X^* is the conjugate transpose of a matrix. Integrals of functions with values in $[0,\infty]$ are Lebesgue integrals; for measures μ, ν on a group, $\mu * \nu$ is the image of $\mu \times \nu$ under the multiplication. Elements written x, y, u, k are elements of $G(T)$, and g is a unit of A, where nothing else is said.

Forms and groups. These notions belong to the background library. The index set $I(\mathfrak{s})$ consists of $e_0, \dots, e_{\varrho-1}$, of the elements of κ, of z, and of $e_0^*, \dots, e_{\varrho-1}^*$. The *frame* is $\mathfrak{f}_a = e_a$ for $a < \varrho$ and $\mathfrak{f}_\varrho = z$. An $\mathfrak{s}$-form T is a hermitian matrix indexed by $\kappa \sqcup \{z\}$; its *split Gram matrix* $J(T)$, indexed by $I(\mathfrak{s})$, pairs e_a with e_a^* to 1 and is T on the middle; $G(T)$ is the unitary group of $J(T)$ over A, with the form $h(v,v') = v^* J(T) v'$, so that the coordinate of a vector w at e_a^* is $h(e_a, w)$. For $x \in G(T)$, $Z_T(x) = (h(\mathfrak{f}_a, x\,\mathfrak{f}_{a'}))_{a,a' \le \varrho}$ is its *frame Gram matrix*; its corner entry is $Z_T(x)_{\varrho\varrho} = h(z, xz)$. The *level* of an index is a for e_a, ϱ for the middle indices, and $2\varrho - a$ for e_a^*. In $G(T)$: $\mathcal{U}(T)$ is the *Bessel unipotent subgroup*, the elements that are block upper triangular for the levels with identity diagonal blocks; $\mathcal{H}(T)$ is the subgroup of the elements that fix all e_a, all e_a^* and z; $\mathcal{H}_l(T)$, for $l \le \varrho$, the subgroup of those that fix e_a and e_a^* for $a < l$, and $\mathcal{H}_{\varrho+1}(T) = \mathcal{H}(T)$; $\mathcal{Q}_l(T)$ is the group of the elements that are unitriangular on the first l floors; and $\mathcal{S}(T) = \mathcal{U}(T)\mathcal{H}(T)$ is the *Bessel subgroup*. For $u \in G(T)$, $\mathrm{sd}(u) = \sum_{a<\varrho} h(e_a^*, u\,\mathfrak{f}_{a+1})$ is the sum of the entries of u just above the diagonal of its frame block. For a sequence p of units and $l \le \varrho$, $w_l(p) \in G(T)$ is the *Weyl element* of length l: it sends e_a to $p_a e_a^*$ and e_a^* to $\bar{p}_a^{-1} e_a$ for $a < l$ and fixes the other basis vectors. For a unit g of A, $K_T(g)$ is the group of the $k \in G(T)$ that have entries in O_A, as has k^{-1}, and for which $g^{-1}(k-1)$ has entries in O_A; so $K_T(1)$ is the group of the *integral isometries*.

Levels and the tower. These notions belong to the unit on the real place (the notes *The tower method at a place*); they are recalled with their arguments. A *level* $\mathcal{L} \in \mathrm{Lev}(\iota, T, m+1)$ consists of a hyperbolic basis of the middle form with $m+1$ further hyperbolic pairs and an orthonormal part indexed by ι; a unit $g_\mathcal{L}$ of A with $\overline{g_\mathcal{L}} = g_\mathcal{L}$; s-finite measures $\theta_\varrho(\mathcal{L})$, carried by $\mathcal{H}_\varrho(T)$, and $\theta_n(\mathcal{L}) \neq 0$, carried by $\mathcal{H}(T)$ and invariant under right translation by its elements; an open set of vectors, the *ball*; a compact set $\mathrm{Box}(\mathcal{L}) \subseteq G(T)$, the *box*; and a measurable set $\mathrm{Posn}(\mathcal{L}) \subseteq G(T)$, the *positions*. Its *congruence subgroup* is $\mathrm{K}^\circ(\mathcal{L}) = K_T(g_\mathcal{L})$. The library provides measures η_l on $G(T)$, the *Heisenberg measures* of the floors; $\eta_{<j}$ is the convolution of the first j of them, and $\eta_{<\varrho+2}$ is carried by $\mathcal{U}(T)$. The *floor measures* are $\theta_l(\mathcal{L})$ for $l < \varrho$ (the law of the inverse Weyl element of floor l, convolved with η_l), $\theta_\varrho(\mathcal{L})$, and $\theta_{\varrho+1}(\mathcal{L}) = \theta_n(\mathcal{L})$. For natural numbers l, i the *stack measure* is

$$\mu_{l,i}^{\mathcal{L}} = (\eta_{l+i-1} * \theta_{l+i-1}(\mathcal{L})) * \cdots * (\eta_l * \theta_l(\mathcal{L})),$$

with $\mathsf{M}(\mathcal{L}) = \mu_{0,\varrho+2}^{\mathcal{L}}$, the *group measure*, and $\mathsf{M}_{\ge 0}(\mathcal{L}) = \theta_{\varrho+1}(\mathcal{L}) * \cdots * \theta_0(\mathcal{L})$. The *quadric measure* $\delta^{(\varrho)}(\mathcal{L})$ is the image of $\theta_\varrho(\mathcal{L})$ under $\sigma \mapsto \sigma^{-1} z$, a measure on the vectors $e \in A^{I(\mathfrak{s})}$ with $h(e,e) = h(z,z)$. For a unit g and $l < \varrho$ the *floor modulus* is

$\mathsf{d}_{l}(\mathcal{L};g)=\operatorname{mod}_{A}(g)^{k(\mathfrak{s})+1+2(\varrho-l-1)+1/2}$, and for sequences p, q of units and $j\le\varrho$ the *head density* is

$$\mathsf{h}_{j}(\mathcal{L};p,q)=\prod_{a<j}\operatorname{mod}_{A}(p_{a}q_{a})^{(k(\mathfrak{s})+1+2(\varrho-a-1))/2}.$$

The *volume exponent* is $\mathsf{s}(\mathcal{L})=\#\iota-(3n(\mathfrak{s})+m+2)$. For $a<\varrho$ and $x,y\in G(T)$ the set of *floor values* $\operatorname{Val}_{a}(\mathcal{L};x,y)\subseteq A$ consists of the coordinates $h(e_{a},w)$ of the vectors w whose coordinates at e_{b}^{*}, $b<a$, vanish and for which $x^{-1}w$ and $g_{\mathcal{L}}^{-1}(x^{-1}w-(xy)^{-1}w)$ lie in the ball. A point x is *near at* j if $\xi x\in\operatorname{Box}(\mathcal{L})$ for some $\xi\in\mathcal{Q}_{j}(T)$.

For a function $k\colon G(T)\times G(T)\to\mathbb{C}$ and $j\le\varrho+1$ put

$$\begin{aligned}\mathsf{Av}_{j}(\mathcal{L};k)(g,y)&=\int k(\sigma g,\sigma y)\,d(\theta_{\varrho+1}(\mathcal{L})*\cdots*\theta_{j}(\mathcal{L}))(\sigma),\\ \mathsf{Pv}_{j}(\mathcal{L};k)(g,y)&=\int\bigl|\mathsf{Av}_{j+1}(\mathcal{L};k)(\sigma g,\sigma y)\bigr|\,d\theta_{j}(\mathcal{L})(\sigma),\end{aligned}$$

here with $g,y\in G(T)$. For a finite set X, functions $W,W'\colon G(T)\to\ell^{2}(X)$ and $d\in G(T)$, write $k^{d}_{W,W'}(x,y)=\langle W(x),W'(dy)\rangle$. The *pairing norm* is $\mathrm{PN}(\mathcal{L};W,W')=\iint|\langle W(x),W'(y)\rangle|^{2}\,d\mathsf{M}_{\ge0}(\mathcal{L})(y)\,d\mathsf{M}_{\ge0}(\mathcal{L})(x)$. For $j\le\varrho$, sequences p, q of units, $x,g\in G(T)$ and $\omega\colon G(T)\to\mathbb{C}$, with $d=w_{j}(q)^{-1}w_{j}(p)$, put

$$\begin{aligned}\Phi_{j}(x,g)=\int\!\!\int&\omega(\sigma\tau^{-1})\cdot\mathsf{Av}_{j+1}(\mathcal{L};k^{1}_{W,W})(\sigma g,\sigma gx)\\&\cdot\overline{\mathsf{Av}_{j+1}(\mathcal{L};k^{d}_{W,W})(\tau w_{j}(p)^{-1}g,\tau w_{j}(p)^{-1}gx)}\,d\theta_{j}(\mathcal{L})(\tau)\,d\theta_{j}(\mathcal{L})(\sigma).\end{aligned}$$

Then the *floor form*, its *modulus* at x and its *majorant* at x are

$$\begin{aligned}\mathcal{I}_{j}(\mathcal{L};p,q;W,\omega)&=\mathsf{h}_{j}(\mathcal{L};p,q)\cdot\int\!\!\int\Phi_{j}(x,g)\,d\mathsf{M}(\mathcal{L})(x)\,d\mu^{\mathcal{L}}_{0,j}(g),\\ \mathcal{I}^{\mathrm{mod}}_{j}(\mathcal{L};p,q;W,x,\omega)&=\int|\Phi_{j}(x,g)|\,d\mu^{\mathcal{L}}_{0,j}(g),\\ \mathcal{I}^{\mathrm{maj}}_{j}(\mathcal{L};p,q;W,W',x)&=\int\mathsf{Pv}_{j}(\mathcal{L};k^{1}_{W,W})(g,gx)\\&\qquad\cdot\mathsf{Pv}_{j}(\mathcal{L};k^{d}_{W,W'})(w_{j}(p)^{-1}g,w_{j}(p)^{-1}gx)\,d\mu^{\mathcal{L}}_{0,j}(g).\end{aligned}$$

A function $W\colon G(T)\to\ell^{2}(X)$ is a *cut Bessel function for* $\mathcal{L}$ if it is measurable and bounded, $W(ux)=\psi_{A}(g_{\mathcal{L}}^{-1}\operatorname{sd}(u))W(x)$ for $u\in\mathcal{U}(T)$, and $W(x)\neq0$ implies $ux\in\operatorname{Box}(\mathcal{L})$ for some $u\in\mathcal{U}(T)$. For a measure μ on $G(T)$, such a W and $\gamma\in G(T)$, the *Bessel correlation* $\mathrm{J}(\mu,W;\gamma)\in\ell^{2}(X\times X)$ has the coordinates $\int W(y)_{a}\,\overline{W(\gamma^{-1}y)_{b}}\,d\mu(y)$.

A *gauge* $\Gamma\in\mathrm{Gau}(\mathcal{L})$ provides, for every natural number i, a compact set of the elements of A *of size at most* i, written $\mathrm{sz}_{\Gamma}(x)\le i$, increasing with i, and a constant $\Lambda(\Gamma)\in[2,\infty)$; a vector or a matrix has size at most i if its entries have. A sequence p of units is a *head of length* j *for* Γ, $p\in\mathrm{Hd}_{j}(\Gamma)$, if $(p_{0}\cdots p_{l-1})^{-1}$ has size at most 1 for all $l\le j$. The *self-norm product* $\mathrm{SNP}_{j}(\Gamma;p,q;W,W',x)\in[0,\infty]$ of a gauge is the quantity of that name of the unit on the real place; it enters here only through the inputs.

Standard levels. From the note *Poincaré series of cut Bessel functions* of this unit: $\mathcal{L} \in \mathrm{StdLev}$ (*$\mathcal{L}$ is a standard level*) means that $\mathcal{L}$ is the level of the lattice $O_A^{I(\mathfrak{s})}$ with a bound for an ideal zeta function; what this note uses of it is Input 3. For a unit α of A with $\alpha \in O_A$ and $\bar{\alpha} = \alpha$, $\Gamma_{\mathcal{L}}(\alpha) \in \mathrm{Gau}(\mathcal{L})$ is the *gauge of depth* α of a standard level: x has size at most i exactly if $\alpha^i x \in O_A$, and $\Lambda(\Gamma_{\mathcal{L}}(\alpha)) = 2/\operatorname{mod}_A(\alpha)$. For a natural number K, $j \le \varrho$ and a sequence p of units, the *head weight* is $\Lambda_K(j;p) = \prod_{l<j}[p_0 \cdots p_l]^{K/2}$ if all the partial products $p_0 \cdots p_l$, $l < j$, lie in O_A, and $\Lambda_K(j;p) = 0$ otherwise; $\zeta_A(s) = \sum_I [O_A : I]^{-s}$ is the ideal zeta function of O_A, the sum over the ideals of finite index.

Setting 2.1 (a level)**.** A is a semilocal field with an involution and an integral place structure, $\mathfrak{s}$ is a shape, T is an $\mathfrak{s}$-form over A whose split Gram matrix $J(T)$ is a hermitian unit, ι is a finite set, m a natural number, and $\mathcal{L} \in \mathrm{Lev}(\iota, T, m+1)$ is a level.

Definition 2.2 (the finite Bessel function)**.** Let A be a semilocal field with an involution and an integral place structure, $\mathfrak{s}$ a shape and T an $\mathfrak{s}$-form over A whose split Gram matrix is a hermitian unit. For a unit g of A and $z \in G(T)$,

$$\chi_g(z) = \begin{cases} \psi_A(g^{-1}\,\mathrm{sd}(u)) & \text{if } u^{-1}z \in K_T(g) \text{ for some } u \in \mathcal{U}(T), \\ 0 & \text{if there is no such } u, \end{cases}$$

where in the first case u is a chosen such element; by Lemma 4.1(c) the value does not depend on the choice.

LEAN `IntegralPlace.phase`

Definition 2.3 (intermediate groups and the finite Bessel vector)**.** In Setting 2.1:

(a) $\mathrm{Int}(\mathcal{L})$ is the set of the subgroups Z of $G(T)$ with $\mathrm{K}^\circ(\mathcal{L}) \le Z \le K_T(1)$, the *intermediate groups* of $\mathcal{L}$.

(b) The *unipotent mass* is $\mathsf{v}(\mathcal{L}) = \prod_{l<\varrho} \mathsf{d}_l(\mathcal{L}; g_{\mathcal{L}}) \in [0, \infty]$.

(c) For a subgroup Z of $G(T)$,

$$\mathcal{I}_0(\mathcal{L}; Z) = \int \Big| \int_Z \chi_{g_{\mathcal{L}}}(yxy^{-1})\, d\mathsf{M}(\mathcal{L})(y) \Big|^2 d\mathsf{M}(\mathcal{L})(x) \ \in [0, \infty].$$

(d) For $Z \in \mathrm{Int}(\mathcal{L})$, $\mathrm{Cos}(Z)$ is the set of the cosets $\mathrm{K}^\circ(\mathcal{L})a$, $a \in Z$; it is finite, because $\mathrm{K}^\circ(\mathcal{L})$ is open and Z lies in the compact group $K_T(1)$. Each coset c has a chosen representative $a_c \in Z$.

(e) For $Z \in \mathrm{Int}(\mathcal{L})$ the *mass ratio* is $\mathrm{mr}(Z) = \mathsf{M}(\mathcal{L})(Z) \cdot \mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L})) \cdot \mathsf{v}(\mathcal{L})^{-2} \in [0, \infty]$.

(f) For $Z \in \mathrm{Int}(\mathcal{L})$ and $y \in G(T)$ the *finite Bessel vector* $W_Z(y) \in \ell^2(\mathrm{Cos}(Z))$ has the coordinate $\chi_{g_{\mathcal{L}}}(y\, a_c^{-1})$ at the coset c. We write $\mathsf{k}_Z(x, y) = \langle W_Z(x), W_Z(y) \rangle$ for its kernel.

LEAN `Level.IntermediateGroup` · `Level.unipotentMass` · `Level.floorZeroForm` · `Level.IntermediateGroup.Cosets` · `instance : Fintype Z.Cosets` (the finiteness, an instance without a name) · `Level.IntermediateGroup.massRatio` · `Level.IntermediateGroup.besselVector`

Setting 2.4 (a standard level with an intermediate group)**.** In Setting 2.1, with A, $\mathfrak{s}$, T, ι, m and $\mathcal{L}$ as there: $\mathcal{L}$ is a standard level, $\mathcal{L} \in \mathrm{StdLev}$, and $Z \in \mathrm{Int}(\mathcal{L})$ is an intermediate group of $\mathcal{L}$.

Definition 2.5 (correlations, the top kernel, the energy)**.** In Setting 2.4, write $\varrho = \varrho(\mathfrak{s})$.

(a) For a sequence p of units of A and $l \in G(T)$, the *correlation* is

$$\mathcal{J}(Z;p,l) = \mathsf{h}_{\varrho}(\mathcal{L};p,1)\cdot \mathsf{J}(\mathsf{M}(\mathcal{L}), W_Z(\cdot); w_{\varrho}(p)\,l^{-1}) \;\in\; \ell^2(\mathrm{Cos}(Z)\times\mathrm{Cos}(Z)).$$

(b) For a set $L \subseteq A$ and sequences p, q of units of A, the *top kernel* is

$$\mathcal{K}(L;Z;p,q) = \int_{\{l:\ h(z,l^{-1}z)-p_{\varrho}\in L\}} \langle \mathcal{J}(Z;p,l), \mathcal{J}(Z;q,l)\rangle \, d\mu^{\mathcal{L}}_{\varrho,2}(l) \;\in \mathbb{C}.$$

(c) For a finite set $\mathcal{C}$, a complex matrix R indexed by $\mathcal{C}$, a family $\omega = (\omega_i)_{i\in\mathcal{C}}$ of sequences of units of A and a vector $e \in A^{I(\mathfrak{s})}$, the *energy* is

$$\mathcal{E}(Z;R,\omega,e) = \inf_{l} \int \sum_{x\in \mathrm{Cos}(Z)\times\mathrm{Cos}(Z)} (\mathrm{Re}\ v^* R v)^{+}\, d\theta_n(\mathcal{L})(h) \;\in [0,\infty],$$

where the infimum is over the $l \in \mathcal{H}_{\varrho}(T)$ with $l^{-1}z = e$ (it is ∞ if there is none), v is the vector with the coordinates $v_i = \mathcal{J}(Z;\omega_i,hl)_x$, the index i running over $\mathcal{C}$, and $r^+ = \max(r,0)$. (The index, called p in the formal text, is bound inside the definition; see §8, item 1.)

3 What is taken for granted

The following statements are used and not proved here. Inputs 1 and 5 belong to the background library, Inputs 2 and 4 to the unit on the real place (the notes *The tower method at a place*), Input 3 to the note *Poincaré series of cut Bessel functions* of this unit. They are stated from the dossier's readings of their quoted Lean statements; the statements of Inputs 2 to 4 I also read in the Lean text. No reference to the literature is claimed for any of them: they are statements about the objects of this proof.

Input 1 (the Bessel subgroup and the congruence subgroups; background library). Let A, $\mathfrak{s}$, T be as in the conventions and g a unit of A.

(a) $\mathcal{U}(T) \subseteq \mathcal{S}(T)$, and $\mathcal{S}(T)$ normalises $\mathcal{U}(T)$. For $s, s' \in \mathcal{S}(T)$: $\mathrm{sd}(ss') = \mathrm{sd}(s) + \mathrm{sd}(s')$; and $\mathrm{sd}(h) = 0$ for $h \in \mathcal{H}(T)$.

(b) $K_T(g)$ is an open compact subgroup of $G(T)$, contained in $K_T(1)$ and normalised by it; for $k \in K_T(g)$, $g^{-1}\,\mathrm{sd}(k) \in O_A$.

(c) If $J(T)$ and its inverse have entries in O_A and $g \in O_A$, then every $x \in G(T)$ for which $g^{-1}(x-1)$ has entries in O_A lies in $K_T(g)$.

(d) For a sequence p of units and $l \le \varrho$, $w_l(p)$ commutes with the elements of $\mathcal{H}_l(T)$. $\mathcal{H}(T) \subseteq \mathcal{H}_{\varrho}(T)$; if $\sigma, \tau \in \mathcal{H}_{\varrho}(T)$ and $\sigma^{-1}z = \tau^{-1}z$, then $\sigma\tau^{-1} \in \mathcal{H}(T)$; and $Z_T(hxh')_{\varrho\varrho} = Z_T(x)_{\varrho\varrho}$ for $h, h' \in \mathcal{H}(T)$ and $x \in G(T)$.

(e) For $u \in \mathcal{U}(T)$, $a < \varrho$ and a vector w whose coordinates at e^*_b, $b < a$, vanish, the coordinates of uw and of w at e^*_a agree.

Input 2 (the tower; unit on the real place). In Setting 2.1, write $\varrho = \varrho(\mathfrak{s})$.

(a) *(Measures.)* $\mathsf{M}(\mathcal{L}) = \eta_{<\varrho+2} * \mathsf{M}_{\geq 0}(\mathcal{L})$; $\mathsf{M}(\mathcal{L}) = \mu^{\mathcal{L}}_{\varrho,2} * \mu^{\mathcal{L}}_{0,\varrho}$; $\mu^{\mathcal{L}}_{\varrho,2} = \theta_n(\mathcal{L}) * \theta_\varrho(\mathcal{L})$, and this measure is invariant under right translation by the elements of $\mathcal{H}_\varrho(T)$; $\mu^{\mathcal{L}}_{l,i}$ is carried by $\mathcal{H}_l(T)$, and $\mu^{\mathcal{L}}_{0,0}$ is the unit mass at 1.

(b) *(Pairing kernels.)* Let W be a cut Bessel function for $\mathcal{L}$, $k = k^1_{W,W}$, and suppose that $\mathcal{L}$ has a gauge. Then $|\mathsf{Av}_j(\mathcal{L}; k)(g, y)| \leq \mathsf{Pv}_j(\mathcal{L}; k)(g, y)$ for $j \leq \varrho$ and $g, y \in G(T)$; there is $c < \infty$ with $\int |k(\sigma g, \sigma y)|\, d\mu^{\mathcal{L}}_{\varrho,2}(\sigma) \leq c$ for all g, y; and for every function k', if $\mathsf{Pv}_j(\mathcal{L}; k')(g, y) \neq 0$ then $k'(\sigma g, \sigma y) \neq 0$ for some $\sigma \in \mathcal{H}_j(T)$.

(c) *(Forms.)* For $j \leq \varrho$, sequences p, q of units, W and ω: $|\mathcal{I}_j(\mathcal{L}; p, q; W, \omega)| \leq \mathsf{h}_j(\mathcal{L}; p, q) \cdot \int \mathcal{I}^{\mathrm{mod}}_j(\mathcal{L}; p, q; W, x, \omega)\, d\mathsf{M}(\mathcal{L})(x)$; and if W is a cut Bessel function for $\mathcal{L}$ and $|\omega| \leq 1$, then $\mathcal{I}^{\mathrm{mod}}_j(\mathcal{L}; p, q; W, x, \omega) \leq \mathcal{I}^{\mathrm{maj}}_j(\mathcal{L}; p, q; W, W, x)$ for all x.

(d) *(Near points.)* If W is a cut Bessel function for $\mathcal{L}$ and $W(x) \neq 0$, then x is near at every j; if x is near at j and $\sigma \in \mathcal{H}_j(T)$, then σx is near at j. If Γ is a gauge of $\mathcal{L}$, $j \leq \varrho$, p is a sequence of units, and x and $w_j(p)^{-1}x$ are near at j, then $\mathrm{sz}_\Gamma(p_0 \cdots p_{l-1}) \leq 9n(\mathfrak{s})$ for all $l \leq j$.

(e) *(Correlations.)* Let Γ be a gauge of $\mathcal{L}$, W a continuous cut Bessel function for $\mathcal{L}$, p, q heads of length ϱ for Γ, $x \in \mathcal{H}_\varrho(T)$ and μ a Haar measure of $G(T)$. Then

$$\begin{aligned}&\langle \mathrm{J}(\mu, W; w_\varrho(p)x), \mathrm{J}(\mu, W; w_\varrho(q)x)\rangle \\ &\quad = \int\int \langle W(y_1), W(y_2)\rangle\, \overline{\langle W((w_\varrho(p)x)^{-1}y_1), W((w_\varrho(q)x)^{-1}y_2)\rangle}\, d\mu\, d\mu,\end{aligned}$$

the integral over (y_1, y_2). If $W(y) \neq 0$ and $W((w_\varrho(p)x)^{-1}y) \neq 0$, then $\mathrm{sz}_\Gamma(y) \leq 60n(\mathfrak{s})^2$; and for every i the set of the $y \in G(T)$ with $\mathrm{sz}_\Gamma(y) \leq i$ is compact.

Input 3 (standard levels; note *Poincaré series of cut Bessel functions* of this unit). In Setting 2.1, suppose $\mathcal{L} \in \mathrm{StdLev}$, and write $\varrho = \varrho(\mathfrak{s})$, $n = n(\mathfrak{s})$.

(a) $J(T)$ and its inverse have entries in O_A; $g_{\mathcal{L}} \in O_A$; $\mathrm{Box}(\mathcal{L}) = K_T(1)$; the ball is $O_A^{I(\mathfrak{s})}$; $\mathrm{Posn}(\mathcal{L}) = \{y^{-1}uy : \ y \in G(T),\ u \in \mathcal{U}(T)\} \cdot \mathrm{K}^\circ(\mathcal{L})$; and there is a vector u_0 with $h(u_0, w) = w_z$ for all vectors w and with z-coordinate 0.

(b) $\zeta_A(m)^n \le 1 + 2^{-n}$, hence $\zeta_A(m) \le 2$; $m < 9n$; $13n \le \#\iota$; and $k(\mathfrak{s}) = \#\iota + 2m + 3$.

(c) $\mathsf{M}(\mathcal{L})$ is a Haar measure of $G(T)$, invariant under left and right translations; and $\mathrm{vol}(O_A^\times)^{i+1} \le \mu^{\mathcal{L}}_{l,i+2}(K_T(1))$ whenever $l + i = \varrho$.

(d) *(Unfolding.)* For a unit g of A with $g \in O_A$ and $\bar{g} = g$, an s-finite measure θ on $G(T)$ and $c \in G(T)$:

$$\begin{aligned}&(\eta_{<\varrho+2} * \theta)(\{y : \ yc \in K_T(g)\}) \\ &\qquad = \prod_{l<\varrho} \mathsf{d}_l(\mathcal{L}; g) \cdot \theta(\{y : \ uyc \in K_T(g) \text{ for some } u \in \mathcal{U}(T)\}).\end{aligned}$$

(e) *(Gauges.)* For a unit $\alpha \in O_A$ with $\bar{\alpha} = \alpha$, $\Gamma_{\mathcal{L}}(\alpha)$ is a gauge of $\mathcal{L}$, as described in §2; in every gauge Γ of $\mathcal{L}$ the elements of the box and of the ball have size at most 1, the sizes add under multiplication, and $\mathrm{mod}_A(u) \le \Lambda(\Gamma)^i$ for a unit u with $\mathrm{sz}_\Gamma(u) \le i$.

Input 4 (the estimates of the tower method; unit on the real place). In Setting 2.1, suppose $\mathcal{L} \in \mathrm{StdLev}$; let W be a cut Bessel function for $\mathcal{L}$, $k = k^{1}_{W,W}$, $j \le \varrho(\mathfrak{s})$, p, q sequences of units, Γ a gauge of $\mathcal{L}$, and write $n = n(\mathfrak{s})$, $\varrho = \varrho(\mathfrak{s})$.

(a) *(Positions.)* Let q be a head of length j for Γ, Γ' a second gauge, S a set of positions x with $\mathrm{sz}_{\Gamma'}(g_{\mathcal{L}}^{-1}(x-1)) \le 1$, and $f\colon G(T) \to [0,\infty]$, $\epsilon \in [0,\infty]$ with $f(x)^2 \le \epsilon^2 \cdot \mathrm{SNP}_j(\Gamma; p, q; W, W, x)$ on S. Then

$$\mathsf{h}_j(\mathcal{L}; p, q) \int_S f \, d\mathsf{M}(\mathcal{L}) \;\le\; \epsilon \cdot \mathsf{v}(\mathcal{L}) \cdot \mathrm{PN}(\mathcal{L}; W, W) \cdot \Lambda(\Gamma)^{N_1} \cdot \Lambda(\Gamma')^{N_2},$$

where $N_1 = 1500000n^3 + 1$ and $N_2 = 50000n^2$.

(b) *(The majorant.)* Let p be a head of length j for Γ, x a position and $\phi_0 \in [0,\infty]$. Suppose that, if $\phi_0 < 1$, for every y with $\langle W(y), W(yx)\rangle \neq 0$ such that $w_j(p)^{-1}y$ and $w_j(q)^{-1}yx$ are near at j there is a with $j \le a < \varrho$ and $\mathrm{vol}(\mathrm{Val}_a(\mathcal{L}; y, x)) \le \phi_0$. Then $\mathcal{J}^{\mathrm{maj}}_j(\mathcal{L}; p, q; W, W, x)^2 \le \phi_0^{\mathfrak{s}(\mathcal{L})} \cdot V_0^2 \cdot \mathrm{SNP}_j(\Gamma; p, q; W, W, x)$ with $V_0 = 2^{99 \cdot 13\, n}$, the floor-mass constant of the gauge of depth 1.

(c) *(Frequencies.)* Let p be a head of length j for Γ and x a position. If η, ξ are units with $\psi_A(\xi c) = \psi_A(\eta c)$ for all c with $\mathrm{sz}_\Gamma(c) \le 200n^2$, and $\omega(y) = \psi_A(\xi \cdot Z_T(y)_{jj})$, then $\mathcal{J}^{\mathrm{mod}}_j(\mathcal{L}; p, q; W, x, \omega)^2 \le [\eta]^{\#\iota} \cdot \mathrm{SNP}_j(\Gamma; p, q; W, W, x)$. If $j = i+1$ and $\xi = g_{\mathcal{L}}^{-1}(p_i^{-1} - q_i^{-1})$ is a unit, then $\mathcal{J}^{\mathrm{mod}}_j(\mathcal{L}; p, q; W, x, 1)^2 \le [\xi]^{\#\iota} \cdot \mathrm{SNP}_j(\Gamma; p, q; W, W, x)$.

(d) *(Integrality from floor values.)* Let p, q be heads of length j for Γ and Γ'' a second gauge such that, if $j \neq 0$, $\mathrm{sz}_{\Gamma''}(g_{\mathcal{L}}^{-1}c) \le 1$ for every c with $\mathrm{sz}_\Gamma(c) \le 10n$. Let $x, y \in G(T)$ be such that: there are $u, v \in \mathcal{U}(T)$ with ux, $vxy \in \mathrm{Box}(\mathcal{L})$ and $\mathrm{sz}_{\Gamma''}(g_{\mathcal{L}}^{-1}(vxy - ux)) \le 2$; $w_j(p)^{-1}x$ and $w_j(q)^{-1}xy$ are near at j; and for every a with $j \le a < \varrho$ there is a unit $c \in \mathrm{Val}_a(\mathcal{L}; x, y)$ with $\mathrm{sz}_{\Gamma''}(c^{-1}) \le 1$. Then $\mathrm{sz}_{\Gamma''}(g_{\mathcal{L}}^{-1}(y-1)) \le 99n$.

(e) *(The floor 0.)* $\mathsf{h}_0(\mathcal{L}; p, q) = 1$, $\mathcal{J}^{\mathrm{maj}}_0(\mathcal{L}; 1, 1; W, W, x) = \mathsf{Pv}_0(\mathcal{L}; k)(1, x)^2$, and there is a number $\Sigma_0(x) \in [0,\infty]$ with $\mathrm{SNP}_0(\Gamma; 1, 1; W, W, x) = \Lambda(\Gamma)^{3 \cdot 10^6 n^3} \cdot \Sigma_0(x)^2$ such that, for a position x and $\varepsilon \in [0,\infty]$: if for every $\sigma \in G(T)$ with $k(\sigma, \sigma x) \neq 0$ there is $a < \varrho$ with $\mathrm{vol}(\mathrm{Val}_a(\mathcal{L}; \sigma, x)) \le \varepsilon$, then $\mathsf{Pv}_0(\mathcal{L}; k)(1, x)^2 \le \varepsilon^{\mathfrak{s}(\mathcal{L})} \cdot \Lambda(\Gamma)^{10^4 n\varrho} \cdot \Sigma_0(x)$.

Input 5 (ideals, valuations, Eichler elements; background library). Let A be as in the conventions.

(a) *(Summation over ideals.)* Let s be a natural number with $\zeta_A(s) \le 2$, ρ a measure on a measurable space, S a subset of it, f a function with values in $[0,\infty]$, $V \in [0,\infty]$, and $I \mapsto S(I)$ a family of subsets indexed by the ideals of O_A. If for almost every $x \in S$ there is an ideal I of finite index with $x \in S(I)$ and $[O_A : I]^s \cdot f(x) \cdot \rho(S(I)) \le V$, then $\int_S f\, d\rho \le \zeta_A(s) \cdot V$.

(b) *(Content.)* For a finite family (d_i) of elements of A one of which is 1, there is a unit c of A with $c \in O_A$ such that $\{\varepsilon \in A : \ \varepsilon d_i \in O_A \text{ for all } i\} = cO_A$; this is an ideal of O_A of index $[c]$, and $\bar{c} \in O_A$.

(c) *(Greatest common divisors.)* For units ξ, β of A there are a unit η and $x, c \in O_A$ with $\eta = \xi + c\beta$, $\xi = x\eta$ and $\beta \in \eta O_A$.

(d) *(Primitive matrices.)* If a matrix X over A, with columns indexed by a finite set with a weight function, has a left inverse, there is an invertible matrix b, block upper triangular for the weights, such that Xb has entries in O_A and a left inverse with entries in O_A.

(e) *(Volumes.)* For a unit u, $\mathrm{vol}(\{x : \ ux \in O_A\}) = \mathrm{mod}_A(u)^{-1}$; for a unit $u \in O_A$ the ideal uO_A has index $[u]$; and $\mathrm{vol}(O_A \cap \xi^{-1} O_A) = \mathrm{den}(\xi)^{-1}$. Almost every element of A is a unit.

(f) *(Eichler elements.)* In Setting 2.1, let u_0 be a vector with $h(u_0, w) = w_z$ for all w and with z-coordinate 0. For every vector v there is $\mathrm{E}(v) \in G(T)$, given by a formula that is polynomial in the coordinates of v and in the ring inverse of v_z, with $\mathrm{E}(z) = 1$, such that $\mathrm{E}(v) \in \mathcal{H}_\varrho(T)$ if the coordinates of v at all e_a and e_a^* vanish, and $\mathrm{E}(v)^{-1} z = v$ if $h(v,v) = h(z,z)$ and v_z is a unit.

4 The finite Bessel function and its vector

Lemma 4.1 (the finite Bessel function)**.** *Let A be a semilocal field with an involution and an integral place structure, $\mathfrak{s}$ a shape, T an $\mathfrak{s}$-form over A, g a unit of A, and $x, y, u, k \in G(T)$.*

(a) *If $\chi_g(y) \neq 0$, there is $u' \in \mathcal{U}(T)$ with $u'^{-1} y \in K_T(g)$.*

(b) *$|\chi_g(y)| \le 1$.*

(c) *If $u \in \mathcal{U}(T)$ and $u^{-1} y \in K_T(g)$, then $\chi_g(y) = \psi_A(g^{-1} \,\mathrm{sd}(u))$.*

(d) *If $x \in \mathcal{S}(T)$, $u \in \mathcal{U}(T)$ and $u^{-1} x \in K_T(g)$, then $\chi_g(xy) = \psi_A(g^{-1} \,\mathrm{sd}(u)) \cdot \chi_g(y)$.*

(e) *If $k \in K_T(g)$, then $\chi_g(yk) = \chi_g(y)$.*

(f) *If $u \in \mathcal{U}(T)$, then $\chi_g(uy) = \psi_A(g^{-1} \,\mathrm{sd}(u)) \cdot \chi_g(y)$.*

(g) *The function $z \mapsto \chi_g(z)$ on $G(T)$ is locally constant, hence continuous.*

(h) *$K_T(g) \le K_T(1)$.*

Proof. (a) and (b) are read off Definition 2.2, as ψ_A is unitary. (h) is part of the definition of $K_T(g)$.

(c) Let u_0 be the chosen element, so that $u_0^{-1} y \in K_T(g)$. Then $u_0^{-1} u = (u_0^{-1} y)(u^{-1} y)^{-1}$ lies in $K_T(g)$, so $g^{-1} \,\mathrm{sd}(u_0^{-1} u) \in O_A$ by Input 3(b), and $\psi_A(g^{-1} \,\mathrm{sd}(u_0^{-1} u)) = 1$ because

ψ_A is self-dual. As $\mathrm{sd}(u) = \mathrm{sd}(u_0) + \mathrm{sd}(u_0^{-1}u)$ by Input 3(a), the two values of the character agree.

(d) Suppose first that $u_0^{-1}y \in K_T(g)$ for some $u_0 \in \mathcal{U}(T)$. Then $v = xu_0x^{-1}u$ lies in $\mathcal{U}(T)$, because x normalises it, and $v^{-1}xy = (u^{-1}x)(u_0^{-1}y) \in K_T(g)$. By (c), $\chi_g(xy) = \psi_A(g^{-1}\,\mathrm{sd}(v))$, and $\mathrm{sd}(v) = \mathrm{sd}(x)+\mathrm{sd}(u_0)+\mathrm{sd}(x^{-1})+\mathrm{sd}(u) = \mathrm{sd}(u_0)+\mathrm{sd}(u)$ by additivity. With $\chi_g(y) = \psi_A(g^{-1}\,\mathrm{sd}(u_0))$ this is the claim. If there is no such u_0, then $\chi_g(y) = 0$, and $\chi_g(xy) = 0$ as well: from $v^{-1}xy \in K_T(g)$ with $v \in \mathcal{U}(T)$ one gets $u_0 = x^{-1}vu^{-1}x \in \mathcal{U}(T)$ with $u_0^{-1}y = (u^{-1}x)^{-1}(v^{-1}xy) \in K_T(g)$.

(e) The condition $u^{-1}yk \in K_T(g)$ is the condition $u^{-1}y \in K_T(g)$; so both sides vanish together, and otherwise they are equal by (c). (f) is (d) for $x = u$. (g) By (e) the function is constant on the cosets of the open subgroup $K_T(g)$ (Input 3(b)). □

Lemma 4.2 (intermediate groups)**.** *In Setting 2.1:*

(a) $\mathsf{v}(\mathcal{L}) \neq 0$ *and* $\mathsf{v}(\mathcal{L}) \neq \infty$.
(b) *Every* $Z \in \mathrm{Int}(\mathcal{L})$ *is an open subgroup of* $G(T)$.
(c) *For* $Z \in \mathrm{Int}(\mathcal{L})$ *and* $y \in Z$ *there is a coset* $d \in \mathrm{Cos}(Z)$ *such that, for every* $c \in \mathrm{Cos}(Z)$, $y\,a_c^{-1} \in \mathrm{K}^\circ(\mathcal{L})$ *holds exactly if* $c = d$.
(d) *For every unit* u *of* A, $\mathrm{mod}_A(u)^{-1} = \left(\sqrt{[u]}\right)^2$.

Suppose moreover that $\mathcal{L}$ *is a standard level,* $\mathcal{L} \in \mathrm{StdLev}$.

(e) *If* S *is a subgroup of* $G(T)$ *contained in* $K_T(1)$, *then* $\mathsf{M}(\mathcal{L})(S) \neq \infty$.
(f) *For every* $Z \in \mathrm{Int}(\mathcal{L})$: $\mathrm{mr}(Z) \neq 0$ *and* $\mathrm{mr}(Z) \neq \infty$.

Proof. (a) Each floor modulus is a product of powers of $\mathrm{mod}_A(g_{\mathcal{L}})$, the modulus of a unit, which is neither 0 nor ∞. (b) Z contains the open subgroup $\mathrm{K}^\circ(\mathcal{L})$ (Input 3(b)). (c) Take for d the coset of y: $y\,a_c^{-1} \in \mathrm{K}^\circ(\mathcal{L})$ says that y and a_c lie in the same coset. (d) is the definition of the generalised index. (e) $\mathsf{M}(\mathcal{L})$ is a Haar measure (Input 3(c)) and $K_T(1)$ is compact. (f) Z and $\mathrm{K}^\circ(\mathcal{L})$ are open, hence of positive measure, and of finite measure by (e); with (a) this gives the claim. □

LEAN `Level.unipotentMass_ne_zero_and_ne_top` · `Level.IntermediateGroup.isOpen` · `Level.IntermediateGroup.exists_coset` · `IntegralPlace.inv_md_eq_sqrt_genIndex_sq` · `IntegralPlace.IsStdLevel.groupMeasure_ne_top` · `IntegralPlace.IsStdLevel.massRatio_ne_zero_and_ne_top`

Lemma 4.3 (non-orthogonal Bessel vectors)**.** *In Setting 2.1, let* $Z \in \mathrm{Int}(\mathcal{L})$ *and* $x, y \in G(T)$ *with* $\langle W_Z(x), W_Z(y)\rangle \neq 0$. *Then there are* $u, v \in \mathcal{U}(T)$ *with* $ux \in K_T(1)$ *and* $(ux)^{-1}(vy) \in \mathrm{K}^\circ(\mathcal{L})$.

Proof. For some coset c both $\chi_{g_{\mathcal{L}}}(x\,a_c^{-1})$ and $\chi_{g_{\mathcal{L}}}(y\,a_c^{-1})$ are not zero. By Lemma 4.1(a) there are $u, v \in \mathcal{U}(T)$ such that $k_1 = ux\,a_c^{-1}$ and $k_2 = vy\,a_c^{-1}$ lie in $\mathrm{K}^\circ(\mathcal{L})$. Then $ux = k_1a_c \in K_T(1)$, as $a_c \in Z \leq K_T(1)$, and $(ux)^{-1}(vy) = a_c^{-1}(k_1^{-1}k_2)a_c \in \mathrm{K}^\circ(\mathcal{L})$, because $K_T(1)$ normalises $\mathrm{K}^\circ(\mathcal{L})$ (Input 3(b)). □

LEAN `Level.exists_of_inner_besselVector_ne_zero`

Lemma 4.4 (the form on the congruence subgroup)**.** *In Setting 2.4, with x, y the variables of integration and $g = g_{\mathcal{L}}$,*

$$\int_{\mathrm{K}^\circ(\mathcal{L})} \Big| \int_Z \chi_g(yxy^{-1})\, d\mathsf{M}(\mathcal{L})(y) \Big|^2 d\mathsf{M}(\mathcal{L})(x) = \mathsf{M}(\mathcal{L})(Z)^2 \cdot \mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L})).$$

Proof. For $x \in \mathrm{K}^\circ(\mathcal{L})$ and $y \in Z \le K_T(1)$ the conjugate yxy^{-1} lies in $\mathrm{K}^\circ(\mathcal{L})$, so $\chi_g(yxy^{-1}) = \psi_A(g^{-1}\,\mathrm{sd}(1)) = 1$ by Lemma 4.1(c) with $u = 1$. The inner integral is $\mathsf{M}(\mathcal{L})(Z)$, which is finite by Lemma 4.2(e). □

LEAN `IntegralPlace.IsStdLevel.floorZeroForm_on_congGroup`

Lemma 4.5 (the finite Bessel vector is cut)**.** *In Setting 2.4, the function $y \mapsto W_Z(y)$ is a continuous cut Bessel function for $\mathcal{L}$.*

Proof. Its coordinates are continuous by Lemma 4.1(g) and of modulus at most 1, so its norm is at most $\sqrt{\#\,\mathrm{Cos}(Z)}$. The rule $W_Z(uy) = \psi_A(g_{\mathcal{L}}^{-1}\,\mathrm{sd}(u))W_Z(y)$ for $u \in \mathcal{U}(T)$ is Lemma 4.1(f) in each coordinate. If $W_Z(x) \neq 0$, then $\langle W_Z(x), W_Z(x)\rangle \neq 0$, and Lemma 4.3 gives $u \in \mathcal{U}(T)$ with $ux \in K_T(1) = \mathrm{Box}(\mathcal{L})$ (Input 3(a)). □

LEAN `IntegralPlace.IsStdLevel.isCut_besselVector`

Proposition 4.6 (unfolding along the unipotent subgroup)**.** *In Setting 2.4, for all $y, x \in G(T)$, with $g = g_{\mathcal{L}}$ and u the variable of integration,*

$$\mathsf{v}(\mathcal{L}) \cdot \langle W_Z(y), W_Z(yx)\rangle = \int \mathbf{1}_Z(uy) \cdot \chi_g(uyx(uy)^{-1})\, d\eta_{<\varrho+2}(u).$$

Proof. The measure $\eta_{<\varrho+2}$ is carried by $\mathcal{U}(T)$; let $u \in \mathcal{U}(T)$. We claim that the integrand at u equals

$$\sum_{c \in \mathrm{Cos}(Z)} \mathbf{1}[uy\,a_c^{-1} \in \mathrm{K}^\circ(\mathcal{L})] \cdot \overline{W_Z(y)_c} \cdot W_Z(yx)_c.$$

If $uy \notin Z$, both vanish, since $uy\,a_c^{-1} \in \mathrm{K}^\circ(\mathcal{L})$ would give $uy \in \mathrm{K}^\circ(\mathcal{L})a_c \subseteq Z$. If $uy \in Z$, by Lemma 4.2(c) exactly one coset d has $k = uy\,a_d^{-1} \in \mathrm{K}^\circ(\mathcal{L})$, and the sum is $\overline{\chi_g(y\,a_d^{-1})} \cdot \chi_g(yx\,a_d^{-1})$. Now $y\,a_d^{-1} = u^{-1}k$, so $\chi_g(y\,a_d^{-1}) = \psi_A(g^{-1}\,\mathrm{sd}(u^{-1})) = \overline{\psi_A(g^{-1}\,\mathrm{sd}(u))}$ by Lemma 4.1(c) and Input 3(a); and $uyx(uy)^{-1} = u \cdot (yx\,a_d^{-1}) \cdot k^{-1}$, so $\chi_g(uyx(uy)^{-1}) = \psi_A(g^{-1}\,\mathrm{sd}(u)) \cdot \chi_g(yx\,a_d^{-1})$ by Lemma 4.1(e), (f). This proves the claim. Integrating it, the coset c contributes $\eta_{<\varrho+2}(\{u : uy\,a_c^{-1} \in \mathrm{K}^\circ(\mathcal{L})\}) \cdot \overline{W_Z(y)_c}\, W_Z(yx)_c$. By the unfolding of Input 3(d) for the unit mass at 1, this measure is $\mathsf{v}(\mathcal{L})$ if $u'y\,a_c^{-1} \in \mathrm{K}^\circ(\mathcal{L})$ for some $u' \in \mathcal{U}(T)$, which is the case when $W_Z(y)_c \neq 0$ (Lemma 4.1(a)); and when $W_Z(y)_c = 0$ the term vanishes. The sum over c is $\mathsf{v}(\mathcal{L})\langle W_Z(y), W_Z(yx)\rangle$. □

LEAN `IntegralPlace.IsStdLevel.unipotentMass_mul_inner_besselVector`

Proposition 4.7 (the pairing norm)**.** *In Setting 2.4,* $\mathrm{PN}(\mathcal{L}; W_Z(\cdot), W_Z(\cdot)) \cdot \mathsf{v}(\mathcal{L}) \le \mathrm{mr}(Z)$.

Proof. Write $W = W_Z(\cdot)$, $\mathsf{v} = \mathsf{v}(\mathcal{L})$, and $\nu(x) = \eta_{<\varrho+2}(\{u : ux \in Z\})$ for $x \in G(T)$. By Proposition 4.6 (for the pair x, $x^{-1}y$) and Lemma 4.1(b),

$$\mathsf{v} \cdot |\langle W(x), W(y)\rangle| \le \nu(x) \qquad (x, y \in G(T)). \tag{1}$$

Moreover $\nu(x) \le 1$: as $Z \le K_T(1)$, Input 3(d) for the unit 1 and the unit mass at 1 bounds $\nu(x)$ by $\prod_{l<\varrho} \mathsf{d}_l(\mathcal{L};1) = 1$. Since $\mathsf{M}(\mathcal{L}) = \eta_{<\varrho+2} * \mathsf{M}_{\ge 0}(\mathcal{L})$ (Input 3(a)), $\mathsf{M}(\mathcal{L})(Z) = \int \nu(x)\, d\mathsf{M}_{\ge 0}(\mathcal{L})(x)$. So it suffices to show, for every x,

$$\mathsf{v}^3 \int |\langle W(x), W(y)\rangle|^2 \, d\mathsf{M}_{\ge 0}(\mathcal{L})(y) \;\le\; \nu(x) \cdot \mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L})), \tag{2}$$

and to integrate over x. If $W(x) = 0$ this is clear. Otherwise, as W is cut (Lemma 4.5), there is $u_0 \in \mathcal{U}(T)$ with $b = u_0 x \in K_T(1)$. By the right invariance of $\mathsf{M}(\mathcal{L})$ and Input 3(d) for $\theta = \mathsf{M}_{\ge 0}(\mathcal{L})$ and $c = b^{-1}$,

$$\mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L})) = \mathsf{M}(\mathcal{L})(\{y : \; yb^{-1} \in \mathrm{K}^\circ(\mathcal{L})\}) = \mathsf{v} \cdot \mathsf{M}_{\ge 0}(\mathcal{L})(Y_x),$$
$$Y_x = \{y : \; uyb^{-1} \in \mathrm{K}^\circ(\mathcal{L}) \text{ for some } u \in \mathcal{U}(T)\}.$$

For $y \in Y_x$, (1) and $\nu(x) \le 1$ give $\mathsf{v}^2 |\langle W(x), W(y)\rangle|^2 \le \nu(x)^2 \le \nu(x)$. For $y \notin Y_x$ the inner product vanishes: otherwise Lemma 4.3 gives $u', v' \in \mathcal{U}(T)$ with $u'x \in K_T(1)$ and $v'y \in u'x\,\mathrm{K}^\circ(\mathcal{L})$; then $v'yb^{-1} \in u'u_0^{-1} \cdot b\,\mathrm{K}^\circ(\mathcal{L})\,b^{-1} = u'u_0^{-1}\mathrm{K}^\circ(\mathcal{L})$, since b normalises $\mathrm{K}^\circ(\mathcal{L})$, and $u = u_0 u'^{-1} v'$ shows $y \in Y_x$. Hence the left side of (2) is at most $\mathsf{v} \cdot \nu(x) \cdot \mathsf{M}_{\ge 0}(\mathcal{L})(Y_x) = \nu(x)\mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L}))$. Integrating (2) over x gives $\mathsf{v}^3 \cdot \mathrm{PN}(\mathcal{L}; W, W) \le \mathsf{M}(\mathcal{L})(Z)\, \mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L}))$, which is the claim after division by v^2 (Lemma 4.2(a)). □

LEAN `IntegralPlace.IsStdLevel.pairingNorm_mul_le_massRatio`

Lemma 4.8 (the inner integral as an average)**.** *In Setting 2.4, for every $x \in G(T)$, with y the variable of integration and $g = g_{\mathcal{L}}$,*

$$\Big| \int_Z \chi_g(yxy^{-1})\, d\mathsf{M}(\mathcal{L})(y) \Big| = \big|\mathsf{Av}_0(\mathcal{L}; \mathsf{k}_Z)(1, x)\big| \cdot \mathsf{v}(\mathcal{L}).$$

Proof. The integrand is bounded on Z, which has finite measure. By $\mathsf{M}(\mathcal{L}) = \eta_{<\varrho+2} * \mathsf{M}_{\ge 0}(\mathcal{L})$ and Fubini's theorem the integral is

$$\int \int \mathbf{1}_Z(u\sigma)\, \chi_g(u\sigma x (u\sigma)^{-1})\, d\eta_{<\varrho+2}(u)\, d\mathsf{M}_{\ge 0}(\mathcal{L})(\sigma),$$

and by Proposition 4.6 the inner integral is $\mathsf{v}(\mathcal{L}) \cdot \mathsf{k}_Z(\sigma, \sigma x)$. The integral of $\mathsf{k}_Z(\sigma, \sigma x)$ over σ is $\mathsf{Av}_0(\mathcal{L}; \mathsf{k}_Z)(1, x)$ by definition. □

LEAN `IntegralPlace.IsStdLevel.enorm_integral_phase_eq_upperPairing`

Lemma 4.9 (a lower bound for the mass of the integral group)**.** *In Setting 2.1, suppose $\mathcal{L} \in \mathrm{StdLev}$, and let $B \in [0, \infty]$ with $2 \le B$ and $\mathrm{vol}(O_A \setminus O_A^\times) \le B^{-1}$. Then $2^{-n(\mathfrak{s})} \le \mathsf{M}(\mathcal{L})(K_T(1))$.*

Proof. By Input 3(c) for $l = 0$, $i = \varrho$: $\mathrm{vol}(O_A^\times)^{\varrho+1} \le \mathsf{M}(\mathcal{L})(K_T(1))$; and $\mathrm{vol}(O_A^\times) = 1 - \mathrm{vol}(O_A \setminus O_A^\times) \ge 1 - B^{-1} \ge \frac{1}{2}$. □

LEAN `IntegralPlace.IsStdLevel.inv_two_pow_le_groupMeasure`

5 The shell bound, the frequency bound and the bottom value

In this section $n = n(\mathfrak{s})$ and $\varrho = \varrho(\mathfrak{s})$; in the proofs $g = g_{\mathcal{L}}$ and $W = W_Z(\cdot)$. For a standard level and the gauge $\Gamma_{\mathcal{L}}(\alpha)$, "size at most i" means $\alpha^i x \in O_A$; for $\alpha = 1$ it means integrality.

Lemma 5.1 (floor values)**.** *In Setting 2.4, let $a < \varrho(\mathfrak{s})$ and $x, z, y \in G(T)$ with $\langle W_Z(x), W_Z(z)\rangle \neq 0$. Then there is a unit c of A with $c \in O_A$, $c \in \mathrm{Val}_a(\mathcal{L}; x, y)$ and $\mathrm{vol}(\mathrm{Val}_a(\mathcal{L}; x, y)) \leq \mathrm{mod}_A(c)$.*

Proof. Let X be the matrix with the rows of x^{-1} above the rows of $g^{-1}(x^{-1} - (xy)^{-1})$; it has a left inverse. As the ball is $O_A^{I(\mathfrak{s})}$ (Input 3(a)), $\mathrm{Val}_a(\mathcal{L}; x, y)$ is the set of the coordinates $w_{e_a^*}$ of the vectors w with Xw integral and $w_{e_b^*} = 0$ for $b < a$. By Input 3(d), with the levels of the indices as weights, there is an invertible matrix b, block upper triangular for the levels, such that Xb is integral with an integral left inverse; so Xw is integral exactly if $b^{-1}w$ is. Put $i = e_a^*$. Its level $2\varrho - a$ is shared by no other index, and the indices of higher level are the e_b^* with $b < a$. As b and b^{-1} are block upper triangular, the column w^0 of b at i vanishes at these indices, and $(b^{-1}w)_i = (b^{-1})_{ii}\, w_i$ for every w that vanishes at them. For $w = w^0$ this gives $(b^{-1})_{ii}\, b_{ii} = 1$; let $c = b_{ii}$, a unit. Since Xw^0 is a column of Xb, $c = w_i^0 \in \mathrm{Val}_a(\mathcal{L}; x, y)$. Every element of $\mathrm{Val}_a(\mathcal{L}; x, y)$ is a w_i with $b^{-1}w$ integral and w vanishing at the e_b^*, $b < a$; then $c^{-1}w_i = (b^{-1}w)_i \in O_A$. So $\mathrm{Val}_a(\mathcal{L}; x, y) \subseteq cO_A$, a set of volume $\mathrm{mod}_A(c)$. Finally, by Lemma 4.3 there is $u \in \mathcal{U}(T)$ with $ux \in K_T(1)$; $x^{-1}w^0$ is integral, hence so is $uw^0 = (ux)(x^{-1}w^0)$, and its coordinate at e_a^* is $w_i^0 = c$ by Input 3(e). So $c \in O_A$. □

LEAN `IntegralPlace.IsStdLevel.exists_unit_mem_floorValues`

Lemma 5.2 (non-orthogonal vectors are close)**.** *In Setting 2.4, let Γ be a gauge of $\mathcal{L}$ and $x, y \in G(T)$ with $\langle W_Z(x), W_Z(y)\rangle \neq 0$. Then there are $u, v \in \mathcal{U}(T)$ with $ux \in \mathrm{Box}(\mathcal{L})$, $vy \in \mathrm{Box}(\mathcal{L})$ and $\mathrm{sz}_\Gamma(g_{\mathcal{L}}^{-1}(vy - ux)) \leq 2$.*

Proof. Take u, v from Lemma 4.3. Then $ux \in K_T(1) = \mathrm{Box}(\mathcal{L})$, and $k = (ux)^{-1}(vy)$ lies in $\mathrm{K}^\circ(\mathcal{L})$, so that $vy = (ux)k \in K_T(1)$. Further $g^{-1}(vy - ux) = (ux) \cdot g^{-1}(k - 1)$ is a product of integral matrices; its columns lie in the ball, whose elements have size at most 1 in every gauge (Input 3(e)). □

LEAN `IntegralPlace.IsStdLevel.exists_close_of_inner_ne_zero`

Proposition 5.3 (a gauge adapted to two heads)**.** *In Setting 2.4, let $j \leq \varrho(\mathfrak{s})$, let K be a natural number and p, q sequences of units of A, and suppose that $\mathcal{I}_j^{\mathrm{maj}}(\mathcal{L}; p, q; W_Z(\cdot), W_Z(\cdot), x) \neq 0$ for some $x \in G(T)$. Then there is a unit α of A with $\alpha \in O_A$ and $\bar{\alpha} = \alpha$ such that, for the gauge $\Gamma = \Gamma_{\mathcal{L}}(\alpha)$:*

(i) *$p \in \mathrm{Hd}_j(\Gamma)$ and $q \in \mathrm{Hd}_j(\Gamma)$, and if $j \neq 0$ then $\mathrm{sz}_\Gamma(g_{\mathcal{L}}^{-1}) \leq 1$;*
(ii) *$\mathrm{sz}_\Gamma(p_i^{-1} - q_i^{-1}) \leq 1$ for all $i < j$;*
(iii) *$\Lambda(\Gamma)^E \leq (2/\,\mathrm{mod}_A(g_{\mathcal{L}}))^K \cdot \Lambda_K(j; p) \cdot \Lambda_K(j; q)$ for every natural number E with $4E \leq K$.*

Proof. Write $P_l = p_0 \cdots p_{l-1}$ and $Q_l = q_0 \cdots q_{l-1}$. Since the majorant at x is not zero, there is a point y in the support of $\mu_{0,j}^{\mathcal{L}}$ at which both pivot moduli of its integrand are not zero, hence (Input 3(b)) $\sigma, \tau \in \mathcal{H}_j(T)$ with $\langle W(\sigma y), W(\sigma y x)\rangle \neq 0$ and $\langle W(\tau w_j(p)^{-1} y), W(w_j(q)^{-1} w_j(p) \tau w_j(p)^{-1} y x)\rangle \neq 0$. As τ commutes with the Weyl elements (Input 3(d)), W does not vanish at σy, $\tau w_j(p)^{-1} y$, $\sigma y x$ and $\tau w_j(q)^{-1} y x$.

By Input 3(d), with Lemma 4.5, the points y and $w_j(p)^{-1}y$ are near at j, and so are yx and $w_j(q)^{-1}yx$; hence, for the gauge of depth 1, all P_l and Q_l with $l \le j$ lie in O_A. Put $\beta = \prod_{l\le j} P_l$ and $\gamma = \prod_{l\le j} Q_l$. Then $\beta \in O_A$, $\beta/P_l \in O_A$ for $l \le j$, $\beta/p_i = P_i \cdot (\beta/P_{i+1}) \in O_A$ for $i < j$, and $\Lambda_K(j;p) = [\beta]^{K/2}$ by the multiplicativity of the index; likewise for γ and q. Let

$$\alpha = g \cdot \overline{\beta\gamma} \cdot \beta\gamma,$$

a unit in O_A with $\bar\alpha = \alpha$ (Input 3(a)). Then αP_l^{-1}, αQ_l^{-1} $(l \le j)$, αg^{-1} and $\alpha(p_i^{-1} - q_i^{-1})$ $(i < j)$ lie in O_A, which is (i) and (ii). For (iii), $\Lambda(\Gamma) = 2[\alpha] = 2[g]\,[\beta]^2[\gamma]^2$, and the three indices are at least 1; so for $4E \le K$, $\Lambda(\Gamma)^E \le 2^K[g]^K([\beta][\gamma])^{K/2}$. □

LEAN `IntegralPlace.IsStdLevel.exists_gauge_depth_of_ne_zero`

Proposition 5.4 (the shell bound)**.** *In Setting 2.4, let $j \le \varrho(\mathfrak{s})$, let t be a natural number with $t + 10^8 n(\mathfrak{s})^4 \le k(\mathfrak{s})$, let α be a unit of A with $\alpha \in O_A$ and $\bar\alpha = \alpha$, and let Γ be the gauge $\Gamma = \Gamma_{\mathcal{L}}(\alpha)$. Let p, q be sequences of units of A with $p \in \mathrm{Hd}_j(\Gamma)$, $q \in \mathrm{Hd}_j(\Gamma)$ and, if $j \ne 0$, $\mathrm{sz}_\Gamma(g_{\mathcal{L}}^{-1}) \le 1$. Let $f\colon G(T) \to [0,\infty]$ and $e \in [0,\infty]$ be such that $f(x) \le \mathcal{I}_j^{\mathrm{maj}}(\mathcal{L};p,q;W_Z(\cdot),W_Z(\cdot),x)$ for all x and such that, if $e < 1$, then $f(x)^2 \le \left(e^{\mathfrak{s}(\mathcal{L})}\right)^2 \cdot \mathrm{SNP}_j(\Gamma;p,q;W_Z(\cdot),W_Z(\cdot),x)$ for all $x \in \mathrm{Posn}(\mathcal{L})$. Then*

$$\mathsf{h}_j(\mathcal{L};p,q) \cdot \int f\,d\mathsf{M}(\mathcal{L}) \;\le\; \min(1,e)^t \cdot \mathrm{mr}(Z) \cdot \Lambda(\Gamma)^{10^9 n(\mathfrak{s})^4}.$$

Proof. Write $\Lambda = \Lambda(\Gamma)$, $s = \mathfrak{s}(\mathcal{L})$. By Input 3(b) and the hypothesis on t,

$$s = k(\mathfrak{s}) - 3m - 3n - 5 \;\ge\; 8 \cdot 10^7 n^4 + t. \tag{3}$$

Step 1: f lives on the positions. If $f(x) \ne 0$, the majorant at x is not zero; as in the proof of Proposition 5.3 there is y' with $\langle W(y'), W(y'x)\rangle \ne 0$, and Lemma 4.3 gives $u, v \in \mathcal{U}(T)$ with $(uy')^{-1}(vy'x) \in \mathrm{K}^\circ(\mathcal{L})$, that is, $x \in y'^{-1}(v^{-1}u)y' \cdot \mathrm{K}^\circ(\mathcal{L}) \subseteq \mathrm{Posn}(\mathcal{L})$ (Input 3(a)).

Step 2: shells. For a position x let $I(x)$ be the set of the $\varepsilon \in A$ that multiply 1 and all entries of $g^{-1}(x-1)$ into O_A. By Input 3(b), $I(x) = cO_A$ for a unit $c = c(x) \in O_A$, an ideal of index $[c]$. For an ideal I let $S(I)$ be the set of the positions with $I(x) = I$. By Input 3(a) for the measure $f\,d\mathsf{M}(\mathcal{L})$, the constant function $\mathsf{h}_j(\mathcal{L};p,q)$ and the exponent m (recall $\zeta_A(m) \le 2$), the claim follows, with $2 \cdot 2^{10^5 n^2} \le \Lambda^{10^8 n^4}$, once we show for every position x, with $c = c(x)$ and $S = S(cO_A)$:

$$[c]^m \cdot \mathsf{h}_j(\mathcal{L};p,q) \cdot \int_S f\,d\mathsf{M}(\mathcal{L}) \;\le\; \min(1,e)^t \cdot \mathrm{mr}(Z) \cdot \Lambda^{9\cdot 10^8 n^4} \cdot 2^{10^5 n^2}. \tag{4}$$

Step 3: one shell. Let $\Gamma' = \Gamma_{\mathcal{L}}(\bar c c)$, so $\Lambda(\Gamma') = 2[c]^2$, and let $\phi \in [0,\infty]$ be the number with

$$\phi^{400n^2} = \mathrm{mod}_A(c) \cdot \Lambda^{(10n+1)\cdot 99n}.$$

For $x' \in S$ the matrix $\bar c c \cdot g^{-1}(x'-1)$ is integral, so S consists of positions x' with $\mathrm{sz}_{\Gamma'}(g^{-1}(x'-1)) \le 1$. Put

$$\epsilon = \min(\phi, 1, e)^s \cdot \Lambda^{9999n}.$$

We show in Step 4 that $f(x')^2 \le \epsilon^2 \cdot \mathrm{SNP}_j(\Gamma; p, q; W, W, x')$ for all $x' \in S$. Then Input 3(a), with Lemma 4.5 and Proposition 4.7, gives

$$\mathsf{h}_j(\mathcal{L}; p, q) \cdot \int_S f \, d\mathsf{M}(\mathcal{L}) \;\le\; \epsilon \cdot \mathrm{mr}(Z) \cdot \Lambda^{1500000n^3+1} \cdot \big(2[c]^2\big)^{50000n^2}.$$

By (3),

$$\begin{aligned} \min(\phi, 1, e)^s &\le \phi^{400n^2 \cdot 200000n^2} \cdot \min(1, e)^t \\ &= \mathrm{mod}_A(c)^{200000n^2} \cdot \Lambda^{(10n+1)99n \cdot 200000n^2} \cdot \min(1, e)^t. \end{aligned}$$

The powers of $[c] = \mathrm{mod}_A(c)^{-1}$ are $m + 100000n^2 - 200000n^2 \le 0$, as $m < 9n$; they are at most 1. The exponent of Λ is

$$9999n + 1500000n^3 + 1 + (10n+1) \cdot 99n \cdot 200000n^2 \;\le\; 9 \cdot 10^8 n^4.$$

This is (4).

Step 4: the bound on a shell. Let $x' \in S$. If $e < \min(\phi, 1)$, then $e < 1$ and the hypothesis gives $f(x')^2 \le (e^s)^2\ \mathrm{SNP}_j(\Gamma; p, q; W, W, x') \le \epsilon^2\ \mathrm{SNP}_j(\Gamma; p, q; W, W, x')$. Otherwise $\min(\phi, 1, e) = \min(\phi, 1)$, and by $f \le \mathcal{J}_j^{\mathrm{maj}}(\mathcal{L}; p, q; W, W, \cdot)$ and Input 3(b) for $\phi_0 = \min(\phi, 1)^2$, with $V_0^2 \le \Lambda^{2 \cdot 9999n}$, it suffices to verify the hypothesis of that input. So let $\phi < 1$, and let y be such that $\langle W(y), W(yx')\rangle \ne 0$ and $w_j(p)^{-1}y$, $w_j(q)^{-1}yx'$ are near at j; suppose, for a contradiction, that $\mathrm{vol}(\mathrm{Val}_a(\mathcal{L}; y, x')) > \phi^2$ for all a with $j \le a < \varrho$. By Lemma 5.1 there are units $d_a \in O_A$ with $d_a \in \mathrm{Val}_a(\mathcal{L}; y, x')$ and $\mathrm{vol}(\mathrm{Val}_a(\mathcal{L}; y, x')) \le \mathrm{mod}_A(d_a)$. Let $C = \prod_{j \le a < \varrho} d_a$ and let Γ'' be the gauge of depth $\alpha^{10n+1}\bar{C}C$. Then $C/d_a \in O_A$, so d_a^{-1} has size at most 1 for Γ''; if $j \ne 0$ and c' has size at most $10n$ for Γ, then $\alpha^{10n+1}g^{-1}c' \in O_A$, so $g^{-1}c'$ has size at most 1 for Γ''; and Lemma 5.2 provides the two unipotent elements. Input 3(d), for the pair (y, x'), shows that $\varepsilon = (\alpha^{10n+1}\bar{C}C)^{99n}$ multiplies $g^{-1}(x'-1)$ into O_A; it also lies in O_A. So $\varepsilon \in I(x') = cO_A$, whence $\mathrm{mod}_A(\varepsilon) \le \mathrm{mod}_A(c)$, that is,

$$\mathrm{mod}_A(C)^{198n} \;\le\; \mathrm{mod}_A(c) \cdot \mathrm{mod}_A(\alpha)^{-(10n+1)99n} \;\le\; \mathrm{mod}_A(c) \cdot \Lambda^{(10n+1)99n} = \phi^{400n^2}.$$

On the other hand $\mathrm{mod}_A(C) = \prod_a \mathrm{mod}_A(d_a) > \phi^{2(\varrho - j)}$, or $\mathrm{mod}_A(C) = 1$ if $j = \varrho$; as $\phi < 1$ and $396n(\varrho - j) \le 400n^2$, this gives $\mathrm{mod}_A(C)^{198n} > \phi^{400n^2}$, a contradiction. □

LEAN `IntegralPlace.IsStdLevel.lintegral_shells_le`

Corollary 5.5 (the majorant is integrable)**.** *In Setting 2.4, let $j \le \varrho(\mathfrak{s})$, let r be a natural number with $r + 10^8 n(\mathfrak{s})^4 \le k(\mathfrak{s})$, and let p, q be sequences of units of A. Then $\int \mathcal{J}_j^{\mathrm{maj}}(\mathcal{L}; p, q; W_Z(\cdot), W_Z(\cdot), x)\, d\mathsf{M}(\mathcal{L})(x) \ne \infty$.*

Proof. If the integral is infinite, the majorant is not identically zero; Proposition 5.3, with $K = 0$, gives a gauge $\Gamma = \Gamma_{\mathcal{L}}(\alpha)$ that satisfies the hypotheses of Proposition 5.4, which we apply to f the majorant, $e = 1$ and $t = r$. The right side is finite (Lemma 4.2(f)) and $\mathsf{h}_j(\mathcal{L}; p, q) \ne 0$; a contradiction. □

LEAN `IntegralPlace.IsStdLevel.lintegral_formMajorant_ne_top`

Proof of Theorem A. The function ω has modulus at most 1, so by Input 3(c)

$$\begin{aligned} |\mathcal{J}_j(\mathcal{L}; p, q; W, \omega)| &\le \mathsf{h}_j(\mathcal{L}; p, q) \cdot \int f \, d\mathsf{M}(\mathcal{L}), \\ f(x) = \mathcal{J}_j^{\mathrm{mod}}(\mathcal{L}; p, q; W, x, \omega) &\le \mathcal{J}_j^{\mathrm{maj}}(\mathcal{L}; p, q; W, W, x). \end{aligned} \tag{5}$$

If the majorant vanishes identically, the form is zero. Otherwise let $\Gamma = \Gamma_{\mathcal{L}}(\alpha)$ be the gauge of Proposition 5.3, $\Lambda = \Lambda(\Gamma)$, and $\beta = \alpha^{200n^2}$.

A unit η. We claim that there are units η, w of A with

$$w \in O_A, \quad \xi w \in O_A, \quad \xi\eta^{-1} \in O_A, \quad \min(1,[\eta]) \le \mathrm{mod}_A(w)\cdot \mathrm{mod}_A(\beta)^{-1}, \tag{6}$$

such that $f(x)^2 \le [\eta]^{\#\iota}\cdot \mathrm{SNP}_j(\Gamma;p,q;W,W,x)$ for all positions x. In the second case of the theorem ($j=i+1$, $\omega=1$), take $\eta=\xi$ and $w=\beta$: by (i) and (ii) of Proposition 5.3, ξ has size at most 2 for Γ, so $\xi\beta\in O_A$, and the bound is the second part of Input 3(c). In the first case, Input 3(c) gives a unit η and $x_0, c \in O_A$ with $\eta = \xi + c\beta$, $\xi = x_0\eta$ and $\beta \in \eta O_A$; put $w=\eta^{-1}\beta$. Then $w\in O_A$, $\xi w = x_0\beta \in O_A$, $\xi\eta^{-1}=x_0$, and $\mathrm{mod}_A(w)\,\mathrm{mod}_A(\beta)^{-1}=[\eta]$. For every c' of size at most $200n^2$ for Γ, $(\eta-\xi)c' = c\,\beta c' \in O_A$, so $\psi_A(\eta c') = \psi_A(\xi c')$, and the bound is the first part of Input 3(c).

The shell bound. We apply Proposition 5.4 to f, the number $e=[\eta]^{1/2}$ and $t+12$ in the place of t; note $t+12+10^8n^4 \le k(\mathfrak{s})$. Its second hypothesis holds: if $e<1$, then $[\eta]^{\#\iota} \le [\eta]^{\mathsf{s}(\mathcal{L})} = (e^{\mathsf{s}(\mathcal{L})})^2$, because $\mathsf{s}(\mathcal{L}) \le \#\iota$. With (5) we get

$$|\mathcal{J}_j(\mathcal{L};p,q;W,\omega)| \;\le\; \min(1,e)^t\cdot\min(1,[\eta])^6\cdot \mathrm{mr}(Z)\cdot\Lambda^{10^9n^4}.$$

Now $[\eta]\le[\xi\eta^{-1}][\eta]=[\xi]$, as $\xi\eta^{-1}\in O_A$; so $\min(1,e)^t \le [\xi]^{t/2}$. By (6), $\min(1,[\eta])^6 \le \mathrm{mod}_A(w)^6\,\mathrm{mod}_A(\beta)^{-6}$; here $\mathrm{mod}_A(\beta)^{-6}\le\Lambda^{1200n^2}$ (Input 3(e), as β^{-1} has size at most $200n^2$), and $\mathrm{mod}_A(w)=\mathrm{vol}(wO_A)\le \mathrm{vol}(O_A\cap\xi^{-1}O_A) = \mathrm{den}(\xi)^{-1}$ by Input 3(e), since wO_A is contained in $O_A\cap\xi^{-1}O_A$. Finally $\Lambda^{10^9n^4+1200n^2}\le\Lambda^{2\cdot10^9n^4}\le (2/\mathrm{mod}_A(g))^K\Lambda_K(j;p)\Lambda_K(j;q)$ by Proposition 5.3(iii), as $8\cdot10^9n^4\le K$. This is the bound of Theorem A. □

Proof of Theorem B. Let $\Gamma=\Gamma_{\mathcal{L}}(1)$, so $\Lambda(\Gamma)=2$, and $\epsilon_0=\min(\mathrm{vol}(O_A\setminus O_A^\times),\frac12)$. Split the outer integral of $\mathcal{J}_0(\mathcal{L};Z)$ over $\mathrm{K}^\circ(\mathcal{L})$ and its complement. The first part is $\mathsf{M}(\mathcal{L})(Z)^2\mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L}))$ by Lemma 4.4. In the second, by Lemma 4.8 and Input 3(b) (with Lemma 4.5), the integrand is at most $\mathsf{v}(\mathcal{L})^2\cdot f(x)$, where

$$f(x) = \mathbf{1}[x\notin \mathrm{K}^\circ(\mathcal{L})]\cdot \mathsf{Pv}_0(\mathcal{L};\mathsf{k}_Z)(1,x)^2 = \mathbf{1}[x\notin \mathrm{K}^\circ(\mathcal{L})]\cdot \mathcal{J}_0^{\mathrm{maj}}(\mathcal{L};1,1;W,W,x)$$

(Input 3(e)). We apply Proposition 5.4 with $j=0$, $p=q=1$, $e=\epsilon_0$ and $t+1+n+10^9n^4$ in the place of t; the sequence 1 is a head of length 0, and $t+1+n+10^9n^4+10^8n^4\le k(\mathfrak{s})$. Granting its second hypothesis, and since $\mathsf{h}_0(\mathcal{L};1,1)=1$,

$$\begin{aligned}\mathsf{v}(\mathcal{L})^2\int f\,d\mathsf{M}(\mathcal{L}) \;&\le\; \mathsf{v}(\mathcal{L})^2\,\mathrm{mr}(Z)\cdot\epsilon_0^{t+1}\cdot\epsilon_0^n\cdot(2\epsilon_0)^{10^9n^4}\\ &\le\; \mathsf{M}(\mathcal{L})(Z)\,\mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L}))\cdot\mathrm{vol}(O_A\setminus O_A^\times)^{t+1}\cdot 2^{-n},\end{aligned}$$

which with the first part is the claim.

It remains to show $f(x)^2\le(\epsilon_0^{\mathsf{s}(\mathcal{L})})^2\cdot\mathrm{SNP}_0(\Gamma;1,1;W,W,x)$ for a position $x\notin\mathrm{K}^\circ(\mathcal{L})$. By Input 3(e), and since $2\cdot10^4n\varrho\le3\cdot10^6n^3$, this follows once we show: for every σ with $\mathsf{k}_Z(\sigma,\sigma x)\neq0$ there is $a<\varrho$ with $\mathrm{vol}(\mathrm{Val}_a(\mathcal{L};\sigma,x))\le\epsilon_0$. By Lemma 5.1 there are units $u_a\in O_A$ with $u_a\in\mathrm{Val}_a(\mathcal{L};\sigma,x)$ and $\mathrm{vol}(\mathrm{Val}_a(\mathcal{L};\sigma,x))\le\mathrm{mod}_A(u_a)$. If some u_a is not a unit of O_A, then u_aO_A is a proper ideal contained in $O_A\setminus O_A^\times$, so $\mathrm{mod}_A(u_a)=\mathrm{vol}(u_aO_A)\le\epsilon_0$, and a is the floor we want. Otherwise all u_a^{-1}

are integral. Then Input 3(d), for $\Gamma'' = \Gamma$, $j = 0$ and the pair (σ, x), applies: the unipotent elements come from Lemma 5.2, and every point is near at 0, because $\mathcal{Q}_0(T) = G(T)$. It shows that $g^{-1}(x-1)$ is integral, so $x \in \mathrm{K}^\circ(\mathcal{L})$ by Inputs 3(c) and 3(a), against the choice of x. □

6 The top floor

Again $n = n(\mathfrak{s})$, $\varrho = \varrho(\mathfrak{s})$, $g = g_{\mathcal{L}}$ and $W = W_Z(\cdot)$.

Lemma 6.1 (one gauge for two sequences)**.** *In Setting 2.1, suppose $\mathcal{L} \in \mathrm{StdLev}$, and let p, q be sequences of units of A. Then there is a gauge $\Gamma \in \mathrm{Gau}(\mathcal{L})$ such that all sequences r of units in a neighbourhood of p, and all sequences r in a neighbourhood of q, are heads of length $\varrho(\mathfrak{s})$ for Γ.*

Proof. For $l \le \varrho$ the map $(c, r) \mapsto \bar{c}c \cdot (r_0 \cdots r_{l-1})^{-1}$ from pairs of an element of A and a sequence of units to A is continuous and sends $(0, p)$ and $(0, q)$ to $0 \in O_A$, and O_A is open. So there are a neighbourhood N of 0 and neighbourhoods of p and of q on whose products with N all these maps have values in O_A. Almost every element of A is a unit (Input 3(e)), so N contains a unit c, and $\Gamma = \Gamma_{\mathcal{L}}(\bar{c}c)$ has the property; note $\bar{c}c \in O_A$, the case $l = 0$. □

LEAN `IntegralPlace.IsStdLevel.exists_gauge_isHead`

Proposition 6.2 (the correlations are locally constant)**.** *In Setting 2.4, let p be a sequence of units of A. Then there is a neighbourhood of $(p, 1)$ in the product of the space of sequences of units with $G(T)$ such that for every (p', l') in it with $l' \in \mathcal{H}_\varrho(T)$ and every $l \in \mathcal{H}_\varrho(T)$: $\mathcal{J}(Z; p', ll') = \mathcal{J}(Z; p, l)$.*

Proof. Let Γ be the gauge of Lemma 6.1 for p and 1, and C the set of the $y \in G(T)$ with $\mathrm{sz}_\Gamma(y) \le 60n^2$, a compact set (Input 3(e)). The neighbourhood consists of the (p', l') such that p' is a head of length ϱ for Γ, $p_a^{-1} p'_a \in O_A^\times$ for $a < \varrho$, and

$$k_y = y^{-1}\, w_\varrho(p)\, l'\, w_\varrho(p')^{-1}\, y \in \mathrm{K}^\circ(\mathcal{L}) \qquad \text{for all } y \in C. \tag{7}$$

These are neighbourhood conditions: $O_A^\times$ and $\mathrm{K}^\circ(\mathcal{L})$ are open, the expression in (7) is continuous in (p', l', y) and equal to 1 at $(p, 1, y)$, and C is compact. Let (p', l') be such a pair with $l' \in \mathcal{H}_\varrho(T)$, and $l \in \mathcal{H}_\varrho(T)$. First, $\mathrm{mod}_A(p'_a) = \mathrm{mod}_A(p_a)$ for $a < \varrho$, so $\mathsf{h}_\varrho(\mathcal{L}; p', 1) = \mathsf{h}_\varrho(\mathcal{L}; p, 1)$. Secondly, we show for every $y \in G(T)$

$$W(y) = 0 \qquad \text{or} \qquad W(ll'\, w_\varrho(p')^{-1} y) = W(l\, w_\varrho(p)^{-1} y),$$

which gives the equality of the two Bessel correlations. Suppose $W(y) \neq 0$ and one of the two values on the right is not zero. By Input 3(e), for the head p' and $(ll')^{-1}$, or for the head p and l^{-1}, we get $y \in C$. Then $ll' w_\varrho(p')^{-1} y = l\, w_\varrho(p)^{-1} y \cdot k_y$ with $k_y \in \mathrm{K}^\circ(\mathcal{L})$, and for every coset c the element $a_c k_y a_c^{-1}$ lies in $\mathrm{K}^\circ(\mathcal{L})$ too, so the coordinates at c of the two vectors agree by Lemma 4.1(e). □

LEAN `IntegralPlace.IsStdLevel.eventually_correlation_eq`

Proof of Theorem C. (i) Let Γ be the gauge of Lemma 6.1 for p and q, so that p and q are heads of length ϱ. For $l \in \mathcal{H}_\varrho(T)$, Input 3(e) with $x = l^{-1}$ and $\mu = \mathsf{M}(\mathcal{L})$ (Lemma 4.5, Input 3(c)) gives

$$\begin{aligned}&\langle \mathcal{J}(Z;p,l), \mathcal{J}(Z;q,l)\rangle \\ &\quad = \mathsf{h}_\varrho(\mathcal{L};p,q)\int\int \langle W(x), W(y)\rangle \\ &\qquad\qquad \cdot \langle W(l\,w_\varrho(q)^{-1}y), W(l\,w_\varrho(p)^{-1}x)\rangle \, d\mathsf{M}(\mathcal{L})(x)\, d\mathsf{M}(\mathcal{L})(y),\end{aligned}$$

because $\mathsf{h}_\varrho(\mathcal{L};p,1)\mathsf{h}_\varrho(\mathcal{L};q,1) = \mathsf{h}_\varrho(\mathcal{L};p,q)$. Let $\mathcal{A}(l,x,y)$ be $\varphi_\xi(l^{-1})$ times the integrand on the right. It is integrable for $\mu^{\mathcal{L}}_{\varrho,2}\times \mathsf{M}(\mathcal{L})\times\mathsf{M}(\mathcal{L})$: it vanishes unless x and y lie in the compact set of Input 3(e), and for fixed x, y the integral of its modulus over l is bounded, by the bound for pairing kernels of Input 3(b), since $|\langle W(lw_1), W(lw_2)\rangle| = |k^1_{W,W}(lw_1, lw_2)|$. So F_ξ is integrable, and $\int F_\xi\, d\mu^{\mathcal{L}}_{\varrho,2} = \mathsf{h}_\varrho(\mathcal{L};p,q)\int \mathcal{A}$. We transform $\int\mathcal{A}$. Replace y by xx' (left invariance of $\mathsf{M}(\mathcal{L})$); write $x = sy'$ with $s = h\sigma$, where (h,σ,y') has the law $\theta_n(\mathcal{L})\times\theta_\varrho(\mathcal{L})\times\mu^{\mathcal{L}}_{0,\varrho}$ (Input 3(a)); and replace l by $l's^{-1}$, $l' = k\tau$ with (k,τ) of law $\theta_n(\mathcal{L})\times\theta_\varrho(\mathcal{L})$, which is allowed since $s\in\mathcal{H}_\varrho(T)$ almost surely and $\mu^{\mathcal{L}}_{\varrho,2}$ is invariant under right translation by it. As the Weyl elements commute with $\mathcal{H}_\varrho(T)$ (Input 3(d)),

$$l\,w_\varrho(p)^{-1}x = k\tau w_\varrho(p)^{-1}y' =: z_0, \qquad l\,w_\varrho(q)^{-1}xx' = w_\varrho(q)^{-1}w_\varrho(p)\,z_0\,x',$$
$$\varphi_\xi(l^{-1}) = \varphi_\xi(h\sigma\tau^{-1}k^{-1}) = \varphi_\xi(\sigma\tau^{-1}),$$

the last by Input 3(d). Hence, with $d = w_\varrho(q)^{-1}w_\varrho(p)$,

$$\int\mathcal{A} = \int \varphi_\xi(\sigma\tau^{-1})\cdot\langle W(h\sigma y'), W(h\sigma y'x')\rangle\cdot\overline{\langle W(z_0), W(d\,z_0x')\rangle},$$

the integral over (k,τ,h,σ,x',y'). Integrating first over h and over k turns the two inner products into $\mathsf{Av}_{\varrho+1}(\mathcal{L};k^1_{W,W})(\sigma y',\sigma y'x')$ and the conjugate of $\mathsf{Av}_{\varrho+1}(\mathcal{L};k^d_{W,W})(\tau w_\varrho(p)^{-1}y', \tau w_\varrho(p)^{-1}y'x')$; integrating then over σ and τ gives $\Phi_\varrho(x',y')$ for $\omega = \varphi_\xi$, and the integral over (x',y') for $\mathsf{M}(\mathcal{L})\times\mu^{\mathcal{L}}_{0,\varrho}$, times the head density, is the floor form.

(ii) Let (p_0,q_0) be a pair of sequences. By Proposition 6.2 with $l' = 1$, for (p,q) near (p_0,q_0) the correlations $\mathcal{J}(Z;p,l) = \mathcal{J}(Z;p_0,l)$ and $\mathcal{J}(Z;q,l) = \mathcal{J}(Z;q_0,l)$ agree for all $l\in\mathcal{H}_\varrho(T)$, which carries the measure; and $p_\varrho - (p_0)_\varrho \in L$ for p near p_0, because L is open, so the domain of integration is the same, L being a subgroup. The kernel is locally constant. □

Proof of Theorem D. (i) For $l\in G(T)$ and $x\in\mathrm{Cos}(Z)\times\mathrm{Cos}(Z)$ let $v(l,x)$ be the vector with the coordinates $\mathcal{J}(Z;\omega_i,l)_x$, $i\in\mathcal{C}$. Then

$$\sum_{i,i'} R_{ii'}\langle \mathcal{J}(Z;\omega_i,l), \mathcal{J}(Z;\omega_{i'},l)\rangle = \sum_x v(l,x)^* R\, v(l,x) \;\geq 0,$$

as R is positive semidefinite. Each summand of $\mathcal{Q}$ is an integral of an integrable function (Theorem C(i) for $\xi = 0$), over the same set $D = \{l:\ h(z,l^{-1}z) - t\in L\}$ because $(\omega_i)_\varrho = t$. So $\mathcal{Q} = \int_D \sum_x v(l,x)^* R v(l,x)\, d\mu^{\mathcal{L}}_{\varrho,2}(l)$ is real and ≥ 0, and equals

the integral of $G(l)=\sum_x(\mathrm{Re}\ v(l,x)^{*}Rv(l,x))^{+}$ over D. By $\mu^{\mathcal{L}}_{\varrho,2}=\theta_n(\mathcal{L})*\theta_{\varrho}(\mathcal{L})$, and since $(h\sigma)^{-1}z=\sigma^{-1}z$ for $h\in\mathcal{H}(T)$,

$$\begin{aligned}\mathcal{Q}&=\int \mathbf{1}\big[h(z,\sigma^{-1}z)-t\in L\big]\int G(h\sigma)\,d\theta_n(\mathcal{L})(h)\,d\theta_{\varrho}(\mathcal{L})(\sigma)\\&\geq\int \mathbf{1}\big[h(z,\sigma^{-1}z)-t\in L\big]\cdot\mathcal{E}(Z;R,\omega,\sigma^{-1}z)\,d\theta_{\varrho}(\mathcal{L})(\sigma),\end{aligned}$$

because $\sigma\in\mathcal{H}_{\varrho}(T)$ almost surely and the energy at $\sigma^{-1}z$ is an infimum over a set that contains $l=\sigma$. The right side is at least the integral of the theorem: $\delta^{(\varrho)}(\mathcal{L})$ is the image of $\theta_{\varrho}(\mathcal{L})$ under $\sigma\mapsto\sigma^{-1}z$, and $h(z,e)=(J(T)e)_z$; the integral of a function for an image measure is at most the integral of its composite, with equality for measurable functions, so no measurability of the energy is needed.

(ii) Fix $o\in\Theta_0$; then $l_o e=z$. Let u_0 be the vector of Input 3(a) and E the Eichler elements of Input 3(f). For a vector x put $m(x)=l_o^{-1}\,\mathrm{E}(l_o x)\,l_o$. The z-coordinate of $l_o x$ is 1 at $x=e$; as the units are open and inversion is continuous at 1, for x near e this coordinate is a unit and $m(x)$ is close to $m(e)=1$. By Proposition 6.2, applied to each of the finitely many ω_i, there is a neighbourhood N of e such that for $x\in N$: the z-coordinate of $l_o x$ is a unit, and

$$\mathcal{J}(Z;\omega_i,l\,m(x))=\mathcal{J}(Z;\omega_i,l)\qquad\text{for all } i\in\mathcal{C}\text{ and } l\in\mathcal{H}_{\varrho}(T),\ \text{if } m(x)\in\mathcal{H}_{\varrho}(T).\tag{8}$$

Let $x\in N$, $k\in\mathcal{H}(T)\cap\mathrm{K}^{\circ}(\mathcal{L})$ and y with $ky=x$, and let $l\in\mathcal{H}_{\varrho}(T)$ with $l^{-1}z=y$; we must show $\theta_n(\mathcal{L})(\mathrm{K}^{\circ}(\mathcal{L}))\sum_{\theta}c_{\theta}\leq\int\sum_{x'}G_{x'}(hl)\,d\theta_n(\mathcal{L})(h)$, where $G_{x'}(l')=(\mathrm{Re}\ v^{*}Rv)^{+}$ for the vector $v_i=\mathcal{J}(Z;\omega_i,l')_{x'}$ and $c_{\theta}=G_{n_{\theta}}(l_{\theta})$.

The vector $l_o x=l_o k\,l^{-1}z$ has vanishing coordinates at all e_a, e_a^{*} and satisfies $h(l_o x,l_o x)=h(z,z)$; so $m=m(x)\in\mathcal{H}_{\varrho}(T)$ and $\mathrm{E}(l_o x)^{-1}z=l_o x$, that is, $m\,x=e$. For $\theta\in\Theta_0$ the elements l and $l_{\theta}mk$ of $\mathcal{H}_{\varrho}(T)$ satisfy $(l_{\theta}mk)^{-1}z=k^{-1}m^{-1}e=y=l^{-1}z$, so $b_{\theta}=l\,(l_{\theta}mk)^{-1}\in\mathcal{H}(T)$ by Input 3(d). Thus

$$l=b_{\theta}\,l_{\theta}\,m\,k\qquad(\theta\in\Theta_0).\tag{9}$$

Two invariances of the correlations: for $k'\in\mathcal{H}(T)\cap\mathrm{K}^{\circ}(\mathcal{L})$, $l'\in G(T)$ and a sequence p, $\mathcal{J}(Z;p,k'l')=\mathcal{J}(Z;p,l')=\mathcal{J}(Z;p,l'k')$. Indeed $W(k'y')=W(y')$ for all y', by Lemma 4.1(d) with $u=1$ and $\mathrm{sd}(1)=0$; this gives the first equality in the definition, and the second after the substitution $y'\mapsto k'^{-1}y'$, since k' commutes with $w_{\varrho}(p)$ and $\mathsf{M}(\mathcal{L})$ is left invariant.

Now let $h\in\mathcal{H}(T)$, which carries $\theta_n(\mathcal{L})$, and let θ be such that $hb_{\theta}\in\mathrm{K}^{\circ}(\mathcal{L})$. By (9), the two invariances and (8), $\mathcal{J}(Z;\omega_i,hl)=\mathcal{J}(Z;\omega_i,(hb_{\theta})\,l_{\theta}\,m\,k)=\mathcal{J}(Z;\omega_i,l_{\theta})$ for all i, so $G_{n_{\theta}}(hl)=c_{\theta}$. If also $hb_{\theta'}\in\mathrm{K}^{\circ}(\mathcal{L})$, then $l_{\theta}l_{\theta'}^{-1}=b_{\theta}^{-1}b_{\theta'}\in\mathrm{K}^{\circ}(\mathcal{L})$ by (9); so $\theta\mapsto n_{\theta}$ is injective on the set of these θ, by the hypothesis. Hence

$$\sum_{\theta}\mathbf{1}\big[hb_{\theta}\in\mathrm{K}^{\circ}(\mathcal{L})\big]\cdot c_{\theta}\ \leq\ \sum_{x'}G_{x'}(hl).$$

Integrating over h and using the invariance of $\theta_n(\mathcal{L})$ under right translation by $b_{\theta}\in\mathcal{H}(T)$, the left side becomes $\theta_n(\mathcal{L})(\mathrm{K}^{\circ}(\mathcal{L}))\sum_{\theta}c_{\theta}$. $\square$

7 Where the results are used

All results are used inside the unit. Note F (*Translates of Poincaré series fill the rows*) quotes them as its Input 5, for the form T in the lattice basis of the filling data over the product of the completions at a finite set of places: Lemma 4.1(a), (c), (e) and Lemma 4.2(c) (its part (a)); Theorem B and Lemma 4.4 (b); Lemma 4.9 and Lemma 4.2(f) (c); Theorem A (d); Theorem C (e); Theorem D(i) (f); Theorem D(ii) (g); Lemma 4.5, Corollary 5.5 and Lemma 4.8 (h). The facts that this note recalls and does not prove, and that Note F uses as well (the Haar property and the upper bound for the mass of the integral group, the conditions on the measure on $\mathcal{H}(T)$, the descent and the bound of a floor form by its modulus), are Input 10 of Note F, with the notes that own them. Note G (*From amplitude sums to local correlations*) uses Definition 2.2, Lemma 4.1, the finite Bessel vector and the correlations in its unfolding theorem, Lemma 4.2(a) and Lemma 4.2(e), and the notion of an intermediate group.

8 Notes on the formal text

1. *Arguments that the census reads differently from Lean; to be settled by* `#check` *on a build.* The census reads the arguments from the text, and counts a variable of the file as an argument when its name occurs in a declaration. For the energy (Definition 2.5(c)) it lists five explicit arguments, among them a sequence p; in the definition p is the index of the family, bound inside, and both uses of the energy in the Lean text (the two statements of Theorem D) apply it to four arguments: Z, R, ω and the vector. The note writes these four. The same happens with the letter r in Lemma 6.1, with p in both parts of Theorem D, and with u in Definition 2.2: each is bound in the statement and has no counterpart as an argument. In the other direction, the census does not list Z, p, q for Theorem C(i), nor Z for Theorem D(i), although the statements name these variables of the file; the note states them. Implicit elements x, y, k, g that the census lists for many statements are bound variables, or parts of other names, and have no counterpart either.
2. *Generality.* The form $\mathcal{J}_0(\mathcal{L}; Z)$ is defined for every subgroup Z and every level; the theorems take an intermediate group of a standard level. Lemma 4.1 is stated in the formal text without the hypothesis that the split Gram matrix is a hermitian unit.
3. *The bound for the Bessel vector.* In Lemma 4.5 the bound of the norm is $\sqrt{\#\,\mathrm{Cos}(Z)}$, from coordinates of modulus at most 1; the dossier's first reading said that the norm is at most 1, and the second reader corrected it. Nothing depends on the value of the bound.
4. *Arguments that a conclusion does not name.* In Corollary 5.5 the number r occurs only in the hypothesis $r + 10^8 n(\mathfrak{s})^4 \le k(\mathfrak{s})$, which thus says $10^8 n(\mathfrak{s})^4 \le k(\mathfrak{s})$. In Theorem B the number t is free, so the bound holds with the largest t allowed. In Proposition 5.3 the hypothesis is the existence of one point where the majorant does not vanish; it is used only to see that the partial products of p and q are integral.
5. *Hypotheses on the ring.* Theorem D(ii) assumes that the units of A form an open set and that inversion is continuous at 1. Both hold for a finite product of local

fields; they are hypotheses here because the formal notion of a semilocal field is axiomatic. In Theorem D(ii) the matrix R is arbitrary.

6. *Forms of the formal statements.* Proposition 5.4 is stated in the formal text for a gauge Γ together with an equation that identifies it with a gauge of some depth; $[\xi]^{t/2}$ in Theorem A is written as a power of $\sqrt{[\xi]}$, and the denominator index enters through its inverse; the inequality $j \le \varrho(\mathfrak{s})$ is needed to name the diagonal entry $Z_T(x)_{jj}$. Differences of natural numbers (the volume exponent, the exponents of the floor moduli) are truncated at 0 in the formal text. In Theorem D(i) the formal statement says $0 \le \mathcal{Q}$ for the order of the complex numbers, and bounds the integral by the real part of $\mathcal{Q}$.
7. *Constants.* The exponents 10^8, 10^9, 10^{10} are those of the formal text; the proofs above show which smaller numbers are used: Proposition 5.4 needs $\mathsf{s}(\mathcal{L}) \ge 8 \cdot 10^7 n(\mathfrak{s})^4 + t$, and Theorem A applies it with $t + 12$, which gives the sixth power of the denominator index.
8. *What was not re-derived.* The statements of Inputs 2 and 4 are the results of the tower method; this note uses them as stated. The formal proof of Theorem C(i) verifies the change of variables as an equality of the laws of two functions on product spaces; the text above gives the substitutions. The measurability of the functions that are integrated is checked in the formal text and not discussed here.

How this note was written. From the structured proofs of the module on the top floor in the third chunk of the unit's dossier, all of whose statements and claims a second reader had re-read; her remarks were taken into account. I read the module in the Lean text line by line and compared every statement of this note with it argument by argument; I read in the Lean text the definitions of the unit on the real place and of the note on standard levels that are recalled in §2, and the statements of Inputs 2 to 4. Inputs 1 and 5 are stated from the dossier's readings and from the way the formal proofs use them; of these I read in the Lean text the statements on primitive matrices, on Eichler elements, on the summation over ideals and the definition of a valuation pair. Arguments that are mine and replace computations of the formal text: the proof of Lemma 5.1 in terms of the lattice of the vectors w with Xw integral, the bookkeeping of the exponents in Proposition 5.4, and the description of the change of variables in Theorem C(i). Nothing was compiled for this note. The program check of the unit's dossier covered 1371 leaf steps of 179 proofs.

Appendix A. Concordance with the Lean artifact

The formal names of the objects and the letters of this note: `phase` is $\chi_g(z)$; `unitaryLevel`, `congGroup` are $K_T(g)$, $\mathrm{K}^\circ(\mathcal{L})$; `besselU`, `besselH`, `besselS`, `GT`, `unitriGroup` are $\mathcal{U}(T)$, $\mathcal{H}(T)$, $\mathcal{S}(T)$, $\mathcal{H}_l(T)$, $\mathcal{Q}_l(T)$; `simpleRootSum`, `frameGram`, `weylElem` are $\mathrm{sd}(u)$, $Z_T(x)$, $w_l(p)$; `md`, `genIndex`, `denomIndex`, `idealZeta` are mod_A, $[u]$, $\mathrm{den}(\xi)$, $\zeta_A(s)$; `groupMeasure`, `upperMeasure`, `floorMeasure`, `measureH`, `stackMeasure`, `floorQuadric` are $\mathsf{M}(\mathcal{L})$, $\mathsf{M}_{\ge 0}(\mathcal{L})$, $\theta_l(\mathcal{L})$, $\theta_n(\mathcal{L})$, $\mu^{\mathcal{L}}_{l,i}$, $\delta^{(\varrho)}(\mathcal{L})$; `ascConv` `heisenbergMeasure` is $\eta_{<j}$; `floorModulus`, `headDensity`, `volumeExponent`, `floorValues` are $\mathsf{d}_l(\mathcal{L};g)$, $\mathsf{h}_j(\mathcal{L};p,q)$, $\mathsf{s}(\mathcal{L})$, $\mathrm{Val}_a(\mathcal{L};x,y)$; `upperPairing`, `pivotModulus`, `pairingNorm` are $\mathsf{Av}_j(\mathcal{L};k)(g,y)$, $\mathsf{Pv}_j(\mathcal{L};k)(g,y)$, $\mathrm{PN}(\mathcal{L};W,W')$; `floorForm`, `formModulus`, `formMajorant`, `selfNormProduct` are $\mathcal{J}_j(\mathcal{L};p,q;W,\omega)$ and its modulus,

majorant and self-norm product; `besselCorrelation`, `finHeadWeight` are $\mathrm{J}(\mu, W; \gamma)$, $\Lambda_K(j; p)$; `IsStdLevel.gauge`, `Gauge.Λ`, `IsHead` are $\Gamma_{\mathcal{L}}(\alpha)$, $\Lambda(\Gamma)$, $p \in \mathrm{Hd}_j(\Gamma)$; the level `F` is $\mathcal{L}$, the index set `j` of Theorem D is $\mathcal{C}$, and `Level.energy` is $\mathcal{E}(Z; R, \omega, e)$. Three statements as the artifact has them:

$\mathsf{d}_l(\mathcal{L}; g)$, $\mathsf{h}_j(\mathcal{L}; p, q)$, $\mathsf{s}(\mathcal{L})$, s, $\mathrm{Val}_a(\mathcal{L}; x, y)$ floor modulus, head density, volume exponent, floor values

$\mathsf{Av}_j(\mathcal{L}; k)(g, y)$, $\mathsf{Pv}_j(\mathcal{L}; k)(g, y)$, $k^d_{W,W'}$, $\mathrm{PN}(\mathcal{L}; W, W')$ averaged kernel, pivot modulus, the kernel of two functions, pairing norm

$\mathcal{I}_j(\mathcal{L}; p, q; W, \omega)$, Φ_j, $\mathcal{I}_j^{\mathrm{mod}}(\mathcal{L}; p, q; W, x, \omega)$, $\mathcal{I}_j^{\mathrm{maj}}(\mathcal{L}; p, q; W, W', x)$ floor form, its integrand, modulus, majorant

Γ, Γ', Γ'', $\mathrm{Gau}(\mathcal{L})$, $\mathrm{sz}_\Gamma(x) \leq i$, $\Lambda(\Gamma)$, Λ, $p \in \mathrm{Hd}_j(\Gamma)$, $\Gamma_{\mathcal{L}}(\alpha)$ gauges, size, the constant, heads, gauge of depth α

$\mathrm{SNP}_j(\Gamma; p, q; W, W', x)$, Σ_0, V_0 self-norm product, its factor at floor 0, the floor-mass constant

$\Lambda_K(j; p)$, $\mathrm{J}(\mu, W; \gamma)$, $\ell^2(X)$ head weight, Bessel correlation, the space $\mathbb{C}^X$ with its inner product

$\chi_g(z)$, $\mathrm{Int}(\mathcal{L})$, Z, $\mathrm{Cos}(Z)$, a_c, $\mathsf{v}(\mathcal{L})$, v, $\mathrm{mr}(Z)$ finite Bessel function, intermediate groups, cosets, representatives, unipotent mass, mass ratio

$\mathcal{J}_0(\mathcal{L}; Z)$, $W_Z(y)$, W, k_Z the form at the bottom, finite Bessel vector, its kernel

$\mathcal{J}(Z; p, l)$, $\mathcal{K}(L; Z; p, q)$, $\mathcal{E}(Z; R, \omega, e)$, G, $G_{x'}$ correlation, top kernel, energy, the integrands of the energy

p, q, r, P_l, Q_l, ω_i, $\mathcal{C}$, R, $\mathcal{Q}$ sequences of units, partial products, a family, its index set, a matrix, the kernel sum

ξ, η, α, β, γ, ϕ, ϕ_0, ϵ, ϵ_0, ε units and real numbers of the proofs (frequency, its modification, depths, products, thresholds)

ω, φ_ξ, F_ξ, $\mathcal{A}$, f, e, E, K, t, B, V, C, D, N, L functions and numbers of the statements; C also a product of floor values or a compact set, D a domain, N a neighbourhood, L a subset of A

x, y, u, v, k, l, b, σ, τ, w, d, c, X, Y_x, i, j, a elements of $G(T)$, vectors, matrices, units, indices, as said at each place

Θ_0, θ, l_θ, n_θ, v_θ, c_θ, b_θ, o, $m(x)$, E, u_0 packets and the objects of the proof of Theorem D

READBACK NOTE 38

From amplitude sums to local correlations: filling levels at finitely many places, and the filling data of the admissible data

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. The second moment of the Poincaré series is a sum of *amplitudes* of rational elements of a unitary group, sorted by classes and by an element of a finite level group. This note is the dictionary that turns such sums into integrals at a finite set T of finite places. It shows that the product of the completions at T carries a standard level whose congruence subgroup reads the principal level of the filling data, that integrality off T and the components at T describe the level groups and the unipotent character, and it proves the *unfolding*: the sum of the amplitudes over a double coset of the unipotent group, cut off at T, is the product of an archimedean Bessel correlation and one coordinate of the local correlation of Note T. A second theorem writes a block of amplitude sums with a given link as a sum of limits of such coset amplitudes as T grows. The last section attaches the filling data to the admissible data of the proof, proves that Bessel systems of the required type exist at the infinite places, and verifies the standing hypotheses of the filling theorem.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, of the Riemann hypothesis and of its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles and that Lean's kernel accepted the proofs; an independent replay is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note (Note G of its unit) treats 34 of the 497 declarations of the unit *Translates of Poincaré series fill the rows*: the modules on the passage from global data to the places of T, on the filling data of the admissible data and on their admissibility. Proved here from the inputs: Theorems A to C and the statements of §§4–6. Theorem D and Proposition 7.3 are assemblies; the note says which inputs they assemble and does not reproduce their arithmetic. Taken for granted and stated as Inputs 1 to 6 in §3: the set-up of the unit, the local theory of Note T, the standard levels, facts on adeles from the background library, and the results on the data from Chapter III and from the units on the columns, the rows and the discrete series. Every statement was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 34 declarations.

1 The statements

The objects are recalled in §2. In brief: S is filling data over a CM field E, $G_S(E)$ the rational unitary group, G_S^{lat} its finite adelic points in the lattice basis, with the level groups $K_g(S) \le K(S)$ and the reduction red_S to the finite group $\mathsf{G}(S)$; $\mathrm{pos}_S(c, c'; \gamma)$ is the position of a rational element for two classes, $\mathrm{loc}_{S,\mathsf{T}}$ takes the components at T, and $a^{\sigma}_{S,\mathsf{T}}(c, s, c'; \gamma)$ is the coset amplitude of the side σ (Definition 2.5).

Theorem A (unfolding). *In Setting 2.4, suppose that $\hat{g}(S)^{-1}$ is integral off T, that E carries Weil data and that S is admissible. Let σ be a side, $\gamma_1 \in \mathcal{H}_\varrho(T_S^{\mathrm{rat}}(E))$, p a sequence of units of E, and c, c' classes such that $\mathrm{pos}_S(c, c'; w_\varrho(p)\gamma_1) \in \mathrm{Int}^{\mathsf{T}}(S)$. Let $Z \in \mathrm{Int}(\mathcal{L})$, $k \in K(S)$, and let $a, b \in \mathrm{Cos}(Z)$ be cosets with $\mathrm{loc}_{S,\mathsf{T}}(k)^{-1} a_a a_b^{-1} \in \mathrm{K}^\circ(\mathcal{L})$. Put $\gamma = w_\varrho(p)\gamma_1$, let p_{T} be the sequence of the components of p at T, and $W^\sigma = W_S^\sigma(\cdot)$.. Then*

$$\begin{aligned} &\mathcal{J}(Z; p_{\mathsf{T}}, \mathrm{loc}_{S,\mathsf{T}}(\mathrm{pos}_S(c, c'; \gamma_1))^{-1})_{(a,b)} \cdot \mathrm{J}(dy, W^\sigma; \mathrm{r}_S^\infty(\gamma)) \\ &\quad = \mathsf{h}_\varrho(\mathcal{L}; p_{\mathsf{T}}, 1) \cdot \mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L})) \cdot a^{\sigma}_{S,\mathsf{T}}(c, \mathrm{red}_S(k), c'; \gamma). \end{aligned}$$

LEAN `Filling.IsFillingLevel.correlation_smul_eq_cosetAmplitude`

Theorem B (blocks as limits of coset amplitudes). *In Setting 2.1, suppose that E carries Weil data and that S is admissible. Let σ be a side, c, c' classes, $s \in \mathsf{G}(S)$ and Λ a link, such that $A^\sigma_S(\mathrm{Tm}^{\mathrm{lk}}_S(\Lambda); c, s, c') \neq 0$ and such that for every $\gamma \in \mathrm{Tm}_S(c, s, c')$ all leading minors of $Z_S(\gamma)$ are non-zero. Then there are a unit t of E, an element $\gamma_1 \in G_S(E)$ and $k \in K(S)$ such that*

(i) *$\gamma_1 \in \mathcal{H}_\varrho(T_S^{\mathrm{rat}}(E))$, $Z_S(\gamma_1)_{\varrho\varrho} = t$, $N(S)^2 < |t_\tau|^2$ for every infinite place τ, $\mathrm{red}_S(k) = s$ and $\Lambda = \mathrm{link}(w_\varrho(1)\gamma_1)$; and*

(ii) *there is a family (L_p) of vectors of $\ell^2(\mathrm{Bc}(S) \times \mathrm{Bc}(S))$, indexed by the maps $p\colon \{0, \dots, \varrho(\mathfrak{s}) - 1\} \to E^\times$, which is summable with sum $A^\sigma_S(\mathrm{Tm}^{\mathrm{lk}}_S(\Lambda); c, s, c')$, such that for every p*

$$a^{\sigma}_{S,\mathsf{T}}(c, s, c'; w_\varrho((p \mid t))\gamma_1) \longrightarrow L_p$$

as T grows in the directed set of the finite sets of finite places of E.

LEAN `Filling.exists_hasSum_cosetAmplitude`

Theorem C (filling levels exist). *In Setting 2.1:*

(i) *Suppose that E carries Weil data, and let T be a finite set of finite places of E that is stable under complex conjugation. Then there are an integral place structure on E_{T} and a level $\mathcal{L}$ of $T_S^{\mathrm{lat}}(E_{\mathsf{T}})$ with $\mathcal{L} \in \mathrm{FL}(S, \mathsf{T})$.*

(ii) *For every finite set T_0 of units of E there are arbitrarily large finite sets T of finite places, stable under complex conjugation, such that t and t^{-1} are integral off T for all $t \in \mathsf{T}_0$, $\hat{g}(S)^{-1}$ is integral off T, $\Lambda(S)$ and its inverse have entries integral off T, and $N(S)^{-1}$ is integral off T.*

(iii) *Every finite adele a is integral off all sufficiently large finite sets T of finite places; and for every $x \in G_S^{\mathrm{lat}}$, $x \in \mathrm{Int}^{\mathsf{T}}(S)$ for all sufficiently large T.*

Theorems A and B are Inputs 4(f) and 4(e) of the main note of the unit (Note F, *Translates of Poincaré series fill the rows*); Theorem C and the lemmas of §4 are its Inputs 4(a) to (c), the lemmas of §5 its Input 4(d), and Theorem D with Definition 7.1 and Proposition 7.3 its Input 9(a).

2 The setting

Conventions. The natural numbers are $0, 1, 2, \ldots$. E is a CM field with its CM type: a number field that is a CM field, with complex conjugation $x \mapsto \bar{x}$, together with the choice of one embedding at each infinite place τ; $x_\tau \in \mathbb{C}$ is the image of $x \in E$ under it, and $f(E)$ is the number of infinite places. A *finite place* w of E is a non-zero prime ideal; $\mathbb{F}_w$ is its residue field, E_w the completion, O_w its integers, $\bar{w}$ the conjugate place. $\mathbb{A}_{E,f}$ is the ring of finite adeles, $\hat{O}_E$ its subring of integral adeles, and ψ_f the standard additive character of $\mathbb{A}_{E,f}$. A finite set T of finite places is *stable under complex conjugation* if it contains $\bar{w}$ with every w; for a finite set T of finite places, $E_{\mathsf{T}} = \prod_{w \in \mathsf{T}} E_w$, $x_{\mathsf{T}} \in E_{\mathsf{T}}$ is the family of the components at T of a finite adele or of an element of E, and $\tilde{y}$ is the extension by zero of $y \in E_{\mathsf{T}}$ to a finite adele. A finite adele is *integral off* T if its components at the places outside T are integral, and an element of E if its image is. The field E is *stably unramified* if it contains a primitive root of unity of order 5040, and E *carries Weil data* if

it is stably unramified and a splitting character in the sense of Chapter III of the handout is given. A *shape* is a triple $\mathfrak{s} = (\varrho, \kappa, k_0)$ of a natural number, a finite set and an element of it; $\varrho(\mathfrak{s}) = \varrho$, $k(\mathfrak{s}) = \#\kappa$, $n(\mathfrak{s}) = \varrho(\mathfrak{s}) + 1$, $r(\mathfrak{s}) = 2\varrho(\mathfrak{s}) + k(\mathfrak{s}) + 1$. A *semilocal field*, an *integral place structure* on it, with its ring of integers, character and modulus, a *level* $\mathcal{L}$, its unit $g_{\mathcal{L}}$ and congruence subgroup $\mathrm{K}^\circ(\mathcal{L})$, the group measure $\mathsf{M}(\mathcal{L})$ and a *standard level* are as in Note T of this unit (*The top floor at a finite place*); on E_{T} the integers are $O_{\mathsf{T}} = \prod_{w \in \mathsf{T}} O_w$, the character is written ψ_{T} and the modulus $\mathrm{mod}_{\mathsf{T}}$. A *side* is one of the two words full, cut; in this note σ always denotes a side. P denotes the parameters of the proof (Chapter III). X^* is the conjugate transpose of a matrix, $\ell^2(X)$ the space $\mathbb{C}^X$ with its inner product, conjugate-linear in the first variable. The letters T, F of the formal text for a set of places and a level are written T and $\mathcal{L}$.

Forms and groups. As in Notes F and T: $I(\mathfrak{s})$ is the index set with $e_0, \dots, e_{\varrho-1}$, the elements of κ, z, and $e_0^*, \dots, e_{\varrho-1}^*$; the frame is $\mathfrak{f}_a = e_a$ $(a < \varrho)$, $\mathfrak{f}_\varrho = z$. For a commutative ring R with involution and an $\mathfrak{s}$-form T over R, $J(T)$ is the split Gram matrix, $G(T)$ its unitary group, $h(v, v') = v^* J(T) v'$, $Z_T(x)$ the frame Gram matrix with corner entry $h(z, xz)$; $\mathcal{U}(T)$, $\mathcal{H}(T)$, $\mathcal{S}(T) = \mathcal{U}(T)\mathcal{H}(T)$ are the Bessel unipotent subgroup, the subgroup fixing all e_a, e_a^* and z, and the Bessel subgroup; $\mathcal{H}_\varrho(T)$ is the subgroup fixing all e_a and e_a^*; $\mathrm{sd}(u)$ is the sum of the entries of u just above the diagonal of its frame block; and for a sequence p of units, $w_\varrho(p)$ is the Weyl element of length ϱ, which sends e_a to $p_a e_a^*$ and e_a^* to $\bar{p}_a^{-1} e_a$ for $a < \varrho$. For $p \colon \{0, \dots, \varrho - 1\} \to R^\times$ and a unit t, $(p \,|\, t)$ is the sequence $p_0, \dots, p_{\varrho-1}, t, 1, 1, \dots$. For a unit π, an element t and $x \in R^\kappa$, the *tail vector* $\mathrm{tv}(\pi, t, x)$ is the vector $x - (\pi\bar{\pi})^{-1} t\, z$, written in the lattice basis below.

Setting 2.1 (filling data)**.** E is a CM field with its CM type, $\mathfrak{s}$ is a shape, and S is filling data over E of shape $\mathfrak{s}$, in the sense of the set-up of this unit (the note *The filling data*). Its components are: a real number $b(S) \geq 1000$; a prime number $N(S) \geq 5$ and a finite idele $\bar{\pi}(S) \in \hat{O}_E$ with $\bar{\pi}(S)\,\overline{\bar{\pi}(S)} = N(S)$; two primes $q_0(S)$, $q_1(S)$ different from $N(S)$, with $g(S) = q_0(S) q_1(S)$; for $i = 0, 1$ a set $\mathrm{Ch}_i(S)$ of $f(E)$ finite places above $q_i(S)$, the *chosen places*, with residue fields of $q_i(S)$ elements and such that the conjugate of a chosen place is never chosen; a generator $\varpi(S)$ of the different of E with $\overline{\varpi(S)} = -\varpi(S)$; an open compact subgroup $K^{\mathrm{col}}(S)$ of the finite adelic unitary group of the standard form on κ, with trivial class automorphism groups; and for every infinite place τ a Bessel system $\mathfrak{B}_\tau(S)$. Among its inequalities: $10^5 \leq \varrho(\mathfrak{s})$, $n(\mathfrak{s})\,[E : \mathbb{Q}] \leq 2^{2\varrho(\mathfrak{s})}$ and $1000\,(2\varrho(\mathfrak{s}) + 2) \leq k(\mathfrak{s})$.

The groups of the set-up. In Setting 2.1, for a commutative ring R with involution over the integers of E: $T_S^{\mathrm{rat}}(R)$ is the $\mathfrak{s}$-form that is the identity on κ and $-N(S)$ at z, and $G_S(R) = G(T_S^{\mathrm{rat}}(R))$; $T_S^{\mathrm{lat}}(R)$ is the Gram matrix of the same form in the *lattice basis*, in which the basis vector x_{k_0} of k_0 is replaced by $\overline{\bar{\pi}(S)}^{-1} x_{k_0} + N(S)^{-1} z$ (the bar in $\bar{\pi}(S)$ is part of the name of the idele; the coefficient is the inverse of its conjugate); $\Lambda(S)$ is the matrix of this change of basis over $\mathbb{A}_{E,f}$, and $G_S^{\mathrm{lat}} = G(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$. The homomorphism $\mathrm{r}_S^f \colon G_S(E) \to G_S^{\mathrm{lat}}$ is the diagonal embedding followed by the change of basis; $\mathrm{r}_S^\infty \colon G_S(E) \to \prod_\tau G_1(\mathfrak{s})$ is the family of the images at the infinite places, rescaled to the real form $G_1(\mathfrak{s})$ of the library by positive numbers, of which $\mathrm{fs}_S(\tau, a) > 0$ $(a \leq \varrho)$ are the *frame scales*; inc_S embeds

the finite adelic points of the unitary group of the standard form on κ into G_S^{lat} as $\mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$. For $\gamma \in G_S(E)$, $Z_S(\gamma) = Z_{T_S^{\mathrm{rat}}(E)}(\gamma)$, $\mathsf{g}_S(\gamma)$ is the *term discriminant*, equal to $d\bar{d}\,(t\bar{t} - N(S)^2)$ when $Z_S(\gamma)$ is diagonal with entries $p_0, \dots, p_{\varrho-1}, t$ and $d = p_0 \cdots p_{\varrho-1}$; $\mathrm{link}(\gamma)$ is the *link* of γ, a subspace attached to γ in the set-up, and for a link Λ, $\mathrm{Tm}_S^{\mathrm{lk}}(\Lambda) = \{\gamma \in G_S(E) : \ \mathsf{g}_S(\gamma) \neq 0,\ \mathrm{link}(\gamma) = \Lambda\}$.

For a finite idele u, $\hat{K}_S(u)$ is the group of the $x \in G_S^{\mathrm{lat}}$ that have entries in $\hat{O}_E$, as has x^{-1}, and for which $u^{-1}(x-1)$ has entries in $\hat{O}_E$. Then $K(S) = \hat{K}_S(1)$, and with $\hat{g}(S)$, the integer $g(S)$ as a finite idele, $K_g(S) = \hat{K}_S(\hat{g}(S))$ is the kernel of the reduction $\mathrm{red}_S \colon K(S) \to \mathsf{G}(S)$ modulo the chosen places, where $\mathsf{G}(S) = \prod_i \prod_{w \in \mathrm{Ch}_i(S)} \mathrm{GL}_{I(\mathfrak{s})}(\mathbb{F}_w)$; for a subgroup B of G_S^{lat}, $\overline{B}^S = \mathrm{red}_S(B \cap K(S))$. The character $\psi_S(x) = \psi_f(-x/\varpi(S))$ of $\mathbb{A}_{E,f}$ is self-dual: $\psi_S(ra) = 1$ for all $r \in \hat{O}_E$ exactly if $a \in \hat{O}_E$; and $\psi_S^{\mathcal{U}}(u) = \psi_S(\hat{g}(S)^{-1}\,\mathrm{sd}(u))$ for $u \in G_S^{\mathrm{lat}}$. For a finite set T of finite places, $\psi_{S,\mathsf{T}}(y) = \psi_S(\tilde{y})$ is the character of E_{T} of the set-up. $\mathrm{Cl}(S)$ is the finite set of the double cosets of the finite adelic unitary group of κ by its rational points and $K^{\mathrm{col}}(S)$; each class c has a chosen representative y_c, and $h_S(c) = \mathrm{inc}_S(y_c)$. For classes c, c' and $\gamma \in G_S(E)$,

$$\mathrm{pos}_S(c, c'; \gamma) = h_S(c)^{-1}\, \mathrm{r}_S^f(\gamma)\, h_S(c') \in G_S^{\mathrm{lat}},$$

and for $s \in \mathsf{G}(S)$ the set of *terms over* (c, s, c') is $\mathrm{Tm}_S(c, s, c') = \{\gamma \in G_S(E) : \mathrm{pos}_S(c, c'; \gamma) \in K(S),\ \mathrm{red}_S(\mathrm{pos}_S(c, c'; \gamma)) = s\}$. $\mathcal{U}_{S,c}$ is the group of the rational $u \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$ with $\mathrm{pos}_S(c, c; u) \in K_g(S)$.

Amplitudes. $\mathrm{Bc}(S)$ is the set of the families $(i_\tau)_\tau$ of indices of the Bessel systems. For a side σ, a point y of $\prod_\tau G_1(\mathfrak{s})$ and $i \in \mathrm{Bc}(S)$, $W_S^\sigma(y)_i$ is the product over τ of the i_τ-th coordinates at y_τ of the full or the cut Bessel function of $\mathfrak{B}_\tau(S)$; $\mathrm{bk}_S^\sigma(\gamma, y) \in \ell^2(\mathrm{Bc}(S) \times \mathrm{Bc}(S))$, the *Bessel kernel*, has the coordinates $W_S^\sigma(y)_i\, \overline{W_S^\sigma(\mathrm{r}_S^\infty(\gamma)^{-1} y)_{i'}}$. With the cutoffs $\beta_{S,c} \geq 0$ of the set-up, functions on $\prod_\tau G_1(\mathfrak{s})$, the *amplitude* of $\gamma \in G_S(E)$ over c, c' and the *amplitude sum* of a set $\Xi \subseteq G_S(E)$ are

$$\begin{aligned} a_S^\sigma(c, c'; \gamma) &= \int \beta_{S,c}(y)\, \beta_{S,c'}(\mathrm{r}_S^\infty(\gamma)^{-1} y)\, \mathrm{bk}_S^\sigma(\gamma, y)\, dy, \\ A_S^\sigma(\Xi; c, s, c') &= \sum_{\gamma \in \Xi \cap \mathrm{Tm}_S(c, s, c')} a_S^\sigma(c, c'; \gamma), \end{aligned}$$

with dy the Haar measure of the set-up; $|a|_S^\sigma(c, c'; \gamma)$ is the same integral with the norm of the Bessel kernel. The *order* is $\mathrm{uo}(S) = g(S)^{f(E)\varrho(\mathfrak{s})(2k(\mathfrak{s})+2\varrho(\mathfrak{s})+1)}$. S is *admissible* if the standing hypotheses of the set-up hold: $K^{\mathrm{col}}(S) = \mathrm{inc}_S^{-1}(K_g(S))$, the reduction red_S is surjective, and the inequalities listed in the proof of Theorem D.

The local objects of Note T. For a finite set T of finite places and a unit u of E_{T}, $K_{S,\mathsf{T}}(u)$ is the group of the $y \in G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ that have entries in O_{T}, as has y^{-1}, and for which $u^{-1}(y-1)$ has entries in O_{T}. For a level $\mathcal{L}$ of $T_S^{\mathrm{lat}}(E_{\mathsf{T}})$: $\mathrm{K}^\circ(\mathcal{L}) = K_{S,\mathsf{T}}(g_{\mathcal{L}})$; $\chi_g(y)$ is the finite Bessel function; $\mathrm{Int}(\mathcal{L})$ the set of the intermediate groups Z, with $\mathrm{K}^\circ(\mathcal{L}) \leq Z \leq K_{S,\mathsf{T}}(1)$; $\mathrm{Cos}(Z)$ the set of the cosets of $\mathrm{K}^\circ(\mathcal{L})$ in Z, each coset c with a representative a_c; $W_Z(y)$ the finite Bessel vector, with the coordinate $\chi_{g_{\mathcal{L}}}(y\, a_c^{-1})$ at c; $\mathsf{v}(\mathcal{L}) = \prod_{l<\varrho} \mathsf{d}_l(\mathcal{L}; g_{\mathcal{L}})$ the unipotent mass, where $\mathsf{d}_l(\mathcal{L}; g) = \mathrm{mod}_{\mathsf{T}}(g)^{k(\mathfrak{s})+1+2(\varrho-l-1)+1/2}$; $\mathsf{h}_\varrho(\mathcal{L}; p, 1)$ the head density;

and for a sequence p of units of E_{T} and $l \in G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$, the correlation is $\mathcal{J}(Z;p,l) = \mathsf{h}_{\varrho}(\mathcal{L};p,1)\cdot \mathrm{J}(\mathsf{M}(\mathcal{L}), W_Z(\cdot); w_{\varrho}(p)\,l^{-1})$, where for a measure μ, a vector-valued function W and a group element γ the *Bessel correlation* $\mathrm{J}(\mu, W;\gamma)$ is the tensor with the coordinates $\int W(y)_i\,\overline{W(\gamma^{-1}y)_{i'}}\,d\mu(y)$. $\eta_{<j}$ is the convolution of the first j Heisenberg measures.

Definition 2.2 (integrality off T and the components at T)**.** In Setting 2.1, let T be a finite set of finite places of E.

(a) For $x \in G_S^{\mathrm{lat}}$ we write $x \in \mathrm{Int}^{\mathsf{T}}(S)$, and say that x is *integral off* T, if the entries of x and of x^{-1} are integral off T.

(b) If T is stable under complex conjugation, $\mathrm{loc}_{S,\mathsf{T}}\colon G_S^{\mathrm{lat}} \to G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ is the homomorphism that takes the components at T of every entry.

LEAN `Filling.IsIntegralOff` · `Filling.toPlaces`

Definition 2.3 (filling levels)**.** In Setting 2.1, let T be a finite set of finite places of E that is stable under complex conjugation, suppose that E_{T} carries an integral place structure, and let

$$\mathcal{L} \in \mathrm{Lev}(\{1,\dots,k(\mathfrak{s}) - 6\varrho(\mathfrak{s}) - 13\}, T_S^{\mathrm{lat}}(E_{\mathsf{T}}), 3\varrho(\mathfrak{s}) + 6)$$

be a level, with $3\varrho(\mathfrak{s}) + 6$ further hyperbolic pairs and an orthonormal part of $k(\mathfrak{s}) - 6\varrho(\mathfrak{s}) - 13$ vectors. Then $\mathcal{L} \in \mathrm{FL}(S,\mathsf{T})$ ($\mathcal{L}$ *is a filling level for* S *at* T) means: $\mathcal{L}$ is a standard level, $\mathcal{L} \in \mathrm{StdLev}$; the character of the place structure is $\psi_{\mathsf{T}} = \psi_{S,\mathsf{T}}$; and $g_{\mathcal{L}} = \hat{g}(S)_{\mathsf{T}}$.

LEAN `Filling.IsFillingLevel`

Setting 2.4 (a filling level)**.** In Setting 2.1, with E, $\mathfrak{s}$ and S as there: T is a finite set of finite places of E that is stable under complex conjugation; E_{T} carries an integral place structure; and $\mathcal{L}$ is a level of $T_S^{\mathrm{lat}}(E_{\mathsf{T}})$ with $\mathcal{L} \in \mathrm{FL}(S,\mathsf{T})$, a filling level.

Definition 2.5 (coset amplitudes)**.** In Setting 2.1, let T be a finite set of finite places of E, σ a side, c, c' classes, $s \in \mathsf{G}(S)$ and $\gamma \in G_S(E)$. The *coset amplitude* is

$$a^{\sigma}_{S,\mathsf{T}}(c,s,c';\gamma) = \sum_{(u,u')} a^{\sigma}_S(c,c';u\gamma u'^{-1}) \;\in\; \ell^2(\mathrm{Bc}(S)\times\mathrm{Bc}(S)),$$

the sum over the pairs (u,u') of elements of $\mathcal{U}(T_S^{\mathrm{rat}}(E))$ with $\mathrm{pos}_S(c,c;u) \in \mathrm{Int}^{\mathsf{T}}(S)$ and $u\gamma u'^{-1} \in \mathrm{Tm}_S(c,s,c')$. The side is an instance argument of the formal definition; it is the superscript σ of the notation, and every statement of this note says which side it is.

LEAN `Filling.cosetAmplitude`

Setting 2.6 (the admissible data)**.** $P = (N_0, d)$ are the parameters of the proof and D is admissible data for P (Chapter III of the handout). Attached to D are the CM field $E(D)$ with its CM type, which carries Weil data; the ranks $m(D)$, $r(D)$, $k(D)$ with $r(D)+1 = k(D)+m(D)$ and $m(D) = 2\varrho(D)+2$; the number $f(D)$ of the infinite places of $E(D)$; the third scale $b(D)$; the level $N(D)$, a prime, and a finite idele $\hat{\pi}(D)$ with $\hat{\pi}(D)\overline{\hat{\pi}(D)} = N(D)$, the principal idele of the integer $\pi_N(D)$ of $E(D)$ of the overview and of Note F; the primes $g_0(D)$, $g_1(D)$ with their chosen places; the generator $\varpi(P)$ of the different; from the units on the columns and on

the seesaw, the index set $X_0(D)$ of the columns, with $k(D)$ elements (Lemma 7.2), the level $K_0^{\mathrm{col}}(D)$ of the columns, the shape $\mathfrak{s}(D) = (\varrho(D), X_0(D), k_0)$ with k_0 the last index, the finite group $\mathsf{G}(D)$, and for every infinite place τ the doubled row parameter $2\varkappa_D(\tau,\cdot)$ and the column weight $\mathsf{w}_D^{\mathrm{col}}(\tau)$, a weight of the unitary group of the columns.

3 What is taken for granted

The following statements are used and not proved here. Inputs 1 to 3 belong to the set-up of this unit (the notes *The filling data*, *Box partitions of arithmetic unipotent groups* and *The energy of amplitude sums*) and, for the big cell, to the background library; Input 4 to Note T and to the note *Poincaré series of cut Bessel functions* of this unit; Input 5 to the background library; Input 6 to Chapter III and to the units on the columns, the rows, the real place and the discrete series. They are stated from the dossier's readings of their quoted Lean statements. Where a classical theorem stands behind an input, its reference is to be confirmed, except where another note is cited for it.

Input 1 (levels and the unipotent character; set-up of this unit). In Setting 2.1, with $\mathcal{U} = \mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and $\mathcal{H} = \mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$:

(a) The kernel of red_S is $\hat{K}_S(\hat{g}(S))$, as said in §2; $\hat{g}(S) \in \hat{O}_E$; the split Gram matrix of $T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})$ and its inverse have entries in $\hat{O}_E$; and the components of $T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})$ at T form $T_S^{\mathrm{lat}}(E_{\mathsf{T}})$, the lattice form for the integer $N(S)$ of E_{T}.

(b) $\psi_S(ra) = 1$ for all $r \in \hat{O}_E$ exactly if $a \in \hat{O}_E$; and $\psi_{S,\mathsf{T}}(x_{\mathsf{T}}) = \psi_S(x)$ for every finite adele x that is integral off T.

(c) For a rational $u \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$ and a class c: $\mathrm{r}_S^f(u) \in \mathcal{U}$ and $\mathrm{pos}_S(c,c;u) \in \mathcal{U}$. If $u, v \in \mathcal{U}$ and h is in the image of inc_S with $u^{-1}h^{-1}vh \in K_g(S)$, then $\psi_S^{\mathcal{U}}(v) = \psi_S^{\mathcal{U}}(u)$.

(d) *(Rational approximation.)* For a class c and $u \in \mathcal{U}$ there is a rational $u_0 \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$ with $u^{-1}\mathrm{pos}_S(c,c;u_0) \in K_g(S)$ and $\psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u_0)) = \psi_S^{\mathcal{U}}(u)$.

(e) For a form T as in Note T over $\mathbb{A}_{E,f}$ or over E_{T}, a unit g, $u \in \mathcal{U}(T)$ and $h \in \mathcal{H}(T)$: if uh lies in the congruence subgroup modulo g, so does h. Every element of $\mathcal{S}(T)$ is such a product uh.

Input 2 (amplitudes; set-up of this unit). In Setting 2.1, let σ be a side and c, c' classes.

(a) *(Partition of unity.)* If E is stably unramified and S admissible, then $\sum_{u \in \mathcal{U}_{S,c}} \beta_{S,c}(\mathrm{r}_S^\infty(u)\, y) = 1$ for every point y.

(b) *(The kernel under unipotent elements.)* For rational $u, u' \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$, $\gamma \in G_S(E)$ and a point y: $\mathrm{bk}_S^\sigma(u\gamma u'^{-1}, \mathrm{r}_S^\infty(u)\, y) = \psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u))^{-1}\, \psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u')) \cdot \mathrm{bk}_S^\sigma(\gamma, y)$.

(c) *(Summability.)* If E is stably unramified and S admissible, then for every $\Xi \subseteq G_S(E)$ and $s \in \mathsf{G}(S)$ the family of the amplitudes $a_S^\sigma(c,c';\gamma)$, $\gamma \in \Xi \cap \mathrm{Tm}_S(c,s,c')$, is summable, and $\sum_{\gamma \in \mathrm{Tm}_S(c,s,c')} |a|_S^\sigma(c,c';\gamma) < \infty$.

Input 3 (the big cell and links; background library and set-up). Let T be an $\mathfrak{s}$-form over a field with involution whose split Gram matrix is hermitian and invertible; here $T = T_S^{\mathrm{rat}}(E)$.

(a) If all leading minors of $Z_T(\gamma)$ are non-zero, there are $u, u' \in \mathcal{U}(T)$, a sequence p of units and $\gamma_1 \in \mathcal{H}_\varrho(T)$ with $\gamma = u^{-1}\, w_\varrho(p)\gamma_1\, u'$.

(b) If $v_1\, w_\varrho(p)\gamma_1\, v_2^{-1} = v_1'\, w_\varrho(q)\gamma_1\, v_2'^{-1}$ with $v_1, v_2, v_1', v_2' \in \mathcal{U}(T)$ and $\gamma_1 \in \mathcal{H}_\varrho(T)$, then $p_a = q_a$ for $a < \varrho$, $v_1 = v_1'$ and $v_2 = v_2'$.

(c) For $\gamma_1 \in \mathcal{H}_\varrho(T)$, $Z_T(w_\varrho(p)\gamma_1)$ is the diagonal matrix with the entries $p_0, \dots, p_{\varrho-1}$ and $h(z, \gamma_1 z)$. For $u, u' \in \mathcal{U}(T)$, the leading minors of $Z_T(u^{-1}\gamma u')$ are those of $Z_T(\gamma)$, the term discriminants of $u^{-1}\gamma u'$ and γ agree, and $\mathrm{link}(u^{-1}\gamma u') = \mathrm{link}(\gamma)$. For $\gamma_1, \gamma_2 \in \mathcal{H}_\varrho(T)$ and sequences p, q of units: $\mathrm{link}(w_\varrho(p)\gamma_1) = \mathrm{link}(w_\varrho(q)\gamma_2)$ exactly if $\gamma_1 = \gamma_2$.

Input 4 (the local theory; Note T and the note on standard levels). Let A be a semilocal field with an involution and an integral place structure, T a form and $\mathcal{L}$ a level as in Note T, with integers O_A, character ψ_A and modulus mod_A.

(a) *(Note T, Lemma on the finite Bessel function.)* For a unit g and $y \in G(T)$: if $\chi_g(y) \neq 0$ there is $u \in \mathcal{U}(T)$ with $u^{-1}y$ in the congruence subgroup modulo g; for every such u, $\chi_g(y) = \psi_A(g^{-1}\,\mathrm{sd}(u))$; $\chi_g(yk) = \chi_g(y)$ for k in that subgroup; and $\chi_g(uy) = \psi_A(g^{-1}\,\mathrm{sd}(u))\chi_g(y)$ for $u \in \mathcal{U}(T)$. Moreover $\mathrm{sd}(h) = 0$ for $h \in \mathcal{H}(T)$, and $\mathrm{sd}(uu') = \mathrm{sd}(u) + \mathrm{sd}(u')$ for $u, u' \in \mathcal{S}(T)$.

(b) *(Standard levels.)* If $\mathcal{L} \in \mathrm{StdLev}$: $\mathsf{M}(\mathcal{L})$ is a Haar measure, invariant under left and right translations and finite on the group of the integral isometries; $\eta_{<\varrho}$ is carried by $\mathcal{U}(T)$ and invariant under right translation by its elements; and for a unit $g \in O_A$ with $\bar{g} = g$, the congruence subgroup modulo g has $\eta_{<\varrho}$-measure $\prod_{l<\varrho} \mathsf{d}_l(\mathcal{L}; g)$.

(c) *(Lattice levels.)* Let $N \in O_A$ with $\bar{N} = N$ be such that the split Gram matrix of the lattice form of the shape $\mathfrak{s}$ for N is a hermitian unit, g a unit of A with $g \in O_A$, $\bar{g} = g$, and ι a finite set, m' a natural number with $k(\mathfrak{s}) = \#\iota + 2m' + 1$. Then that form has a level in $\mathrm{Lev}(\iota, \cdot, m')$ with unit g that is a *lattice level.* A level in $\mathrm{Lev}(\iota, \cdot, m+1)$ is standard exactly if it is a lattice level, $\zeta_A(m)^{n(\mathfrak{s})} \leq 1 + 2^{-n(\mathfrak{s})}$ for the ideal zeta function of O_A, $m < 9n(\mathfrak{s})$, $13n(\mathfrak{s}) \leq \#\iota$, and the unitary group has a Haar measure that is right invariant.

Input 5 (adeles; background library). Let T be a finite set of finite places of E.

(a) *(Extension by zero.)* The map $y \mapsto \tilde{y}$ from E_{T} to $\mathbb{A}_{E,f}$ is additive and multiplicative, $(\tilde{y})_{\mathsf{T}} = y$, $\tilde{y}$ is integral off T, and $\bar{\tilde{y}} = \tilde{\bar{y}}$ if T is stable under complex conjugation. A finite adele lies in $\hat{O}_E$ exactly if it is integral off T and its components at T are integral.

(b) *(Indices and archimedean absolute values.)* With the generalised index $[\cdot]$ of E_{T}: for $x \in E^{\times}$ integral off T, $[x_{\mathsf{T}}]^{1/2} \leq \prod_{\tau} |x_{\tau}|$.

(c) *(Zeta functions.)* The ideal zeta function of O_{T} is at most that of $\hat{O}_E$; and if $n\,[E : \mathbb{Q}] \leq 2^{v}$, then $\zeta_{\hat{O}_E}(u+v+4)^{n} \leq 1 + 2^{-u}$.

(d) *(Unimodular lattices.)* A hermitian matrix b over $\mathbb{A}_{E,f}$ that has, with its inverse, entries in $\hat{O}_E$ is $k^{*}bk = 1$ for some matrix k with k, k^{-1} integral. The image of a Haar measure of a locally compact group, restricted to an open subgroup, under a continuous homomorphism that is surjective on that subgroup is a Haar measure of the image; and E_{T} has a unit δ with $\bar{\delta} = -\delta$, $\delta, \delta^{-1} \in O_{\mathsf{T}}$, and an element $\tau_0 \in O_{\mathsf{T}}$ with $\tau_0 + \bar{\tau}_0 = 1$.

(e) *(Finite groups.)* The stabiliser of a non-zero vector of k^{n} in $\mathrm{GL}_n(k)$, for a finite field k and $n \geq 1$, has index $\#k^{n} - 1$.

Input 6 (the data; Chapter III and other units). In Setting 2.6:

(a) *(Chapter III.)* The logarithmic bounds of the admissible data, in particular $b(D)^{19} \le g_0(D)g_1(D) \le b(D)^{23}$, the window for $\log N(D)$, $k(D) \le a(D)$, $\pi \le b(D)$, and the inequalities of Setting 2.1 for $\mathfrak{s}(D)$ and $b(D)$; the primes $g_i(D)$ are different from $N(D)$, an integral adele is divisible by $g_0(D)g_1(D)$ exactly if it and its conjugate vanish modulo all chosen places, the conjugate of a chosen place is not chosen, and there are $f(D)$ chosen places above each $g_i(D)$; $\varpi(P)$ generates the different and $\overline{\varpi(P)} = -\varpi(P)$.

(b) *(Columns.)* The class automorphism groups of $K_0^{\mathrm{col}}(D)$ are trivial, so that the number of its classes is a class sum, which for a subgroup of K_f is its index times the class sum of K_f; the class sum of K_f is $\mathrm{mass}(E(D), k(D))$; $K_0^{\mathrm{col}}(D)$ is the group of the elements of K_f that reduce to 1 at all chosen places and whose row at the last index is congruent to that of the identity modulo every place dividing $\hat{\pi}(D)$; there are $f(D)$ such places, each with $N(D)$ elements in its residue field, none conjugate to another.

(c) *(The filling data fit.)* The filling data $S(D)$ of Definition 7.1 fit the space $Y_0(D)$ of the rows in the sense of the note on Poincaré series, and every family of residue matrices at the chosen places is the reduction of an integral element of the finite adelic unitary group; consequently $\mathrm{red}_{S(D)}$ is surjective. Under inc_S, an element y lies in $\mathrm{inc}_S^{-1}(K(S))$ exactly if it is integral and its row at k_0 is congruent to that of the identity modulo every place dividing $\bar{\pi}(S)$, and the reduction of $\mathrm{inc}_S(y)$ at a chosen place is 1 exactly if that of y is (set-up of the unit).

(d) *(Bessel functions; units on the discrete series, on the real place and on the exchange.)* For a Harish-Chandra parameter with a large gap: the formal degree is positive and is given by Weyl's dimension polynomial (the reference and its relation to the formal statement are given in Note F, Input 8(g)); the kernel of the discrete series in a frame is idempotent; there is a Bessel function of the type of an irreducible unitary representation of the unitary group of the columns whose matrix coefficient is the coefficient of the lowest type, with the bounds of the Laplace method for steep parameters; a Bessel function with these bounds has a cut pair; the full function of a cut pair satisfies Schur bounds; and a cut Bessel function has band limits.

(e) *(Sizes of the counts.)* A bound for $\#\mathrm{Bc}(S(D))$, the logarithm of the degree $\deg(S(D))$ within an explicit interval, and $|\log(\mathrm{mass}(E(D), i+1)/\mathrm{mass}(E(D), i)) - \cdots|$ bounded for $k(D) \le i < r(D)$, as the formal text states them (the note on the degree bounds of this unit and the library on masses).

(f) *(Line coordinates; unit on the rows.)* With the notation of the note *The height of a ratio of lift volumes*: the polynomial of the line coordinates $\mathrm{lc}_D(j, i, Y)$ in the weight of the first columns is the product Δ of the stacked determinants of the matrices $\mathrm{dr}_D(j, i, Y, \tau)$ along $\mathrm{pe}_D(j)$, read as a polynomial in the first columns with coefficients polynomials in the other columns.

4 The dictionary between adelic and local objects

Lemma 4.1 (lifting from the places of T)**.** *In Setting 2.1, let T be a finite set of finite places of E that is stable under complex conjugation. For every $y \in G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ there is $x \in G_S^{\mathrm{lat}}$ with $\mathrm{loc}_{S,\mathsf{T}}(x) = y$ and $x \in \mathrm{Int}^{\mathsf{T}}(S)$, such that $x \in \mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ if $y \in \mathcal{U}(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$, and $x \in \mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ if $y \in \mathcal{H}(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$.*

Proof. Let $e = y - 1$ and $x = 1 + \tilde{e}$, the extension by zero taken entry by entry. Let J be the split Gram matrix of $T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})$ and J_{T} that of $T_S^{\mathrm{lat}}(E_{\mathsf{T}})$, the matrix of the components of J. Extension by zero is multiplicative and commutes with conjugation (Input 3(a)), and $\tilde{a}\,b = \widetilde{a\,b_{\mathsf{T}}}$ for a finite adele b. So

$$x^* J x - J = \tilde{e}^* J + J\tilde{e} + \tilde{e}^* J \tilde{e} = e^* J_{\mathsf{T}} + \widetilde{J_{\mathsf{T}} e} + e^* J_{\mathsf{T}} e = y^* \widetilde{J_{\mathsf{T}} y} - J_{\mathsf{T}} = 0,$$

and $x \in G_S^{\mathrm{lat}}$. Its components at T are those of y; off T it is the identity, and its inverse is $1 + \widetilde{y^{-1} - 1}$, so $x \in \mathrm{Int}^{\mathsf{T}}(S)$. The groups $\mathcal{U}$ and $\mathcal{H}$ are defined by conditions that certain entries are 0 or 1; these pass from y to x. □

LEAN `Filling.exists_toPlaces_eq`

Lemma 4.2 (level groups at T)**.** *In Setting 2.1, let T be a finite set of finite places of E that is stable under complex conjugation, and $x \in G_S^{\mathrm{lat}}$.*

(a) *For a finite idele u such that u^{-1} is integral off T: $x \in \hat{K}_S(u)$ exactly if $x \in \mathrm{Int}^{\mathsf{T}}(S)$ and $\mathrm{loc}_{S,\mathsf{T}}(x) \in K_{S,\mathsf{T}}(u_{\mathsf{T}})$.*
(b) *$x \in K(S)$ exactly if $x \in \mathrm{Int}^{\mathsf{T}}(S)$ and $\mathrm{loc}_{S,\mathsf{T}}(x) \in K_{S,\mathsf{T}}(1)$.*

Suppose moreover that we are in Setting 2.4, with a filling level $\mathcal{L}$, and that $\hat{g}(S)^{-1}$ is integral off T.

(c) *$x \in K_g(S)$ exactly if $x \in \mathrm{Int}^{\mathsf{T}}(S)$ and $\mathrm{loc}_{S,\mathsf{T}}(x) \in \mathrm{K}^\circ(\mathcal{L})$.*
(d) *For $k, l \in K(S)$: $\mathrm{red}_S(k) = \mathrm{red}_S(l)$ exactly if $\mathrm{loc}_{S,\mathsf{T}}(k)^{-1}\,\mathrm{loc}_{S,\mathsf{T}}(l) \in \mathrm{K}^\circ(\mathcal{L})$.*

Proof. (a) A finite adele is integral exactly if it is integral off T and its components at T are integral (Input 3(a)). If the entries of x are integral off T, so are those of $u^{-1}(x-1)$, because u^{-1} is. So the three conditions that define $\hat{K}_S(u)$ split into $x \in \mathrm{Int}^{\mathsf{T}}(S)$ and the three conditions at T, which define $K_{S,\mathsf{T}}(u_{\mathsf{T}})$. (b) is (a) for $u = 1$. (c) is (a) for $u = \hat{g}(S)$, as $K_g(S) = \hat{K}_S(\hat{g}(S))$ (Input 3(a)) and $\mathrm{K}^\circ(\mathcal{L}) = K_{S,\mathsf{T}}(g_{\mathcal{L}})$ with $g_{\mathcal{L}} = \hat{g}(S)_{\mathsf{T}}$. (d) The reductions agree exactly if $k^{-1}l \in K_g(S)$; as $k^{-1}l \in K(S)$ is integral off T by (b), this is the condition of (c). □

LEAN `Filling.mem_unitaryLevel_iff` · `Filling.mem_latStabilizer_iff` · `Filling.IsFillingLevel.mem_principalLevel_iff` · `Filling.IsFillingLevel.reduction_eq_iff`

Lemma 4.3 (the unipotent character at T)**.** *In Setting 2.4, suppose that $\hat{g}(S)^{-1}$ is integral off T, and let $x \in G_S^{\mathrm{lat}}$ with $x \in \mathrm{Int}^{\mathsf{T}}(S)$. Then $\psi_{\mathsf{T}}(g_{\mathcal{L}}^{-1}\,\mathrm{sd}(\mathrm{loc}_{S,\mathsf{T}}(x))) = \psi_S^{\mathcal{U}}(x)$.*

Proof. The left side is $\psi_{S,\mathsf{T}}(a_{\mathsf{T}})$ for the finite adele $a = \hat{g}(S)^{-1}\,\mathrm{sd}(x)$, because $\psi_{\mathsf{T}} = \psi_{S,\mathsf{T}}$ and $g_{\mathcal{L}} = \hat{g}(S)_{\mathsf{T}}$. As a is integral off T, this is $\psi_S(a) = \psi_S^{\mathcal{U}}(x)$ by Input 3(b). □

LEAN `Filling.IsFillingLevel.psi_simpleRootSum_eq_unipotentChar`

Lemma 4.4 (moduli)**.** *In Setting 2.1, let T be a finite set of finite places of E that is stable under complex conjugation, and suppose that E_{T} carries an integral place structure.*

(a) *For a unit x of E such that x and x^{-1} are integral off T:* $\mathrm{mod}_{\mathsf{T}}(x_{\mathsf{T}})^{1/2} = \left(\prod_\tau |x_\tau|\right)^{-1}$.

Suppose moreover that we are in Setting 2.4, with a filling level $\mathcal{L}$, and that $\hat{g}(S)^{-1}$ is integral off T.

(b) $\mathrm{mod}_{\mathsf{T}}(g_{\mathcal{L}}) = g(S)^{-2f(E)}$.
(c) $\mathrm{uo}(S) \cdot \mathsf{v}(\mathcal{L}) = 1$.

Proof. (a) By Input 3(b) for x and for x^{-1}, $[x_{\mathsf{T}}]^{1/2} \le \prod_\tau |x_\tau|$ and $[x_{\mathsf{T}}]^{-1/2} \le \prod_\tau |x_\tau|^{-1}$; so $[x_{\mathsf{T}}]^{1/2} = \prod_\tau |x_\tau|$, and $\mathrm{mod}_{\mathsf{T}}(x_{\mathsf{T}}) = [x_{\mathsf{T}}]^{-1}$. (b) is (a) for the integer $x = g(S)$, whose absolute value at every infinite place is $g(S)$; its inverse is integral off T by hypothesis. (c) By (b),

$$\mathsf{v}(\mathcal{L}) = \prod_{l<\varrho} g(S)^{-2f(E)\,(k(\mathfrak{s})+1+2(\varrho-l-1)+1/2)} = g(S)^{-f(E)\,\varrho\,(2k(\mathfrak{s})+2\varrho+1)},$$

since $\sum_{l<\varrho}(k(\mathfrak{s}) + \frac{3}{2} + 2(\varrho - l - 1)) = \varrho(k(\mathfrak{s}) + \varrho + \frac{1}{2})$; this is $\mathrm{uo}(S)^{-1}$. □

LEAN `IntegralPlace.md_evalPlaces_rpow_half` · `Filling.IsFillingLevel.md_g` · `Filling.IsFillingLevel.g_pow_mul_unipotentMass`

Proof of Theorem C. (iii) A finite adele is integral at all but finitely many places; so are the finitely many entries of x and of x^{-1}.

(ii) Given a finite set T' of finite places, the finitely many finite adeles in question are integral off every sufficiently large set, by (iii); choose such a set that contains T', and add the conjugates of its places.

(i) Write $A = E_{\mathsf{T}}$. *The place structure.* By Input 3(d) there are a unit δ with $\bar{\delta} = -\delta$ and an element τ_0 with $\tau_0 + \bar{\tau}_0 = 1$, integral with integral inverse of δ. The data of the structure are: δ and τ_0; the Haar measure of the skew elements that gives mass 1 to the integral ones; the modulus $\mathrm{mod}_{\mathsf{T}}(u) = [u]^{-1}$; the character $\psi_{S,\mathsf{T}}$; and the Plancherel constant 1. The character is self-dual: for $a \in A$, $\psi_{S,\mathsf{T}}(ra) = 1$ for all $r \in O_{\mathsf{T}}$ exactly if $\psi_S(r'\tilde{a}) = 1$ for all $r' \in \hat{O}_E$, that is, exactly if $\tilde{a} \in \hat{O}_E$ (Input 3(b)), that is, $a \in O_{\mathsf{T}}$ (Input 3(a)). The formal text verifies the further axioms of a place structure for these data: the decomposition of the Haar measure of A along the map $(\beta, \beta') \mapsto \tau_0\delta\beta + \beta'$ from pairs of skew elements, the continuity of the modulus, a locally integrable majorant of $[x]^{1/2}$, and Plancherel's inequality, whose kernel is the indicator function of O_{T} by the self-duality.

The level. By Input 3(a), $T_S^{\mathrm{lat}}(E_{\mathsf{T}})$ is the lattice form for $N(S)$, and its split Gram matrix is a hermitian unit. Put $\iota = \{1, \dots, k(\mathfrak{s}) - 6\varrho - 13\}$ and $m' = 3\varrho + 6$; then $k(\mathfrak{s}) = \#\iota + 2m' + 1$, as $6\varrho + 13 \le k(\mathfrak{s})$. The unit $g = \hat{g}(S)_{\mathsf{T}}$ is integral and fixed by the involution. By Input 3(c) there is a lattice level $\mathcal{L}$ with $g_{\mathcal{L}} = g$. It is standard, with $m = 3\varrho + 5$: by Input 3(c), for $u = n(\mathfrak{s})$, $v = 2\varrho$ and $n = n(\mathfrak{s})$, and by $n(\mathfrak{s})[E : \mathbb{Q}] \le 2^{2\varrho}$ (Setting 2.1), $\zeta_A(m)^{n(\mathfrak{s})} \le \zeta_{\hat{O}_E}(m)^{n(\mathfrak{s})} \le 1 + 2^{-n(\mathfrak{s})}$; $m < 9n(\mathfrak{s})$; and $13n(\mathfrak{s}) \le k(\mathfrak{s}) - 6\varrho - 13$ because $1000(2\varrho + 2) \le k(\mathfrak{s})$. Finally the unitary group $G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ has a Haar measure invariant on both sides: by Input 3(d) the lattice has an orthonormal basis over $\hat{O}_E$, which identifies G_S^{lat} with the finite adelic unitary group of the standard form, a group with a Haar measure invariant on both sides; the elements that are integral off T form an open subgroup, on which $\mathrm{loc}_{S,\mathsf{T}}$ is surjective by Lemma 4.1; and the image of the restricted measure is a Haar measure of the image. So $\mathcal{L} \in \mathrm{FL}(S, \mathsf{T})$. □

Proposition 4.5 (counting reductions by a measure)**.** *In Setting 2.4, suppose that $\hat{g}(S)^{-1}$ is integral off T. Let B be a subgroup of G_S^{lat} and μ an s-finite measure on $G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$ such that μ-almost every z is $\mathrm{loc}_{S,\mathsf{T}}(x)$ for some $x \in B$ with $x \in \mathrm{Int}^{\mathsf{T}}(S)$, and such that μ is invariant under right translation by $\mathrm{loc}_{S,\mathsf{T}}(x)$ for every $x \in B$. Then $\#\overline{B}^S \cdot \mu(\mathrm{K}^\circ(\mathcal{L})) = \mu(K_{S,\mathsf{T}}(1))$.*

Proof. For every $s \in \overline{B}^S$ choose $k_s \in B \cap K(S)$ with $\mathrm{red}_S(k_s) = s$, and let $C_s = \{z : z\,\mathrm{loc}_{S,\mathsf{T}}(k_s) \in \mathrm{K}^\circ(\mathcal{L})\}$. By the invariance, $\mu(C_s) = \mu(\mathrm{K}^\circ(\mathcal{L}))$. The sets C_s are pairwise disjoint: if $z \in C_s \cap C_t$, then $\mathrm{loc}_{S,\mathsf{T}}(k_s)^{-1}\mathrm{loc}_{S,\mathsf{T}}(k_t) \in \mathrm{K}^\circ(\mathcal{L})$, so $s = t$ by Lemma 4.2(d). Their union is $K_{S,\mathsf{T}}(1)$ up to a μ-null set. Indeed, each C_s lies in $K_{S,\mathsf{T}}(1)$, because $\mathrm{K}^\circ(\mathcal{L})$ and $\mathrm{loc}_{S,\mathsf{T}}(k_s)$ do (Lemma 4.2(b)). Conversely let $z = \mathrm{loc}_{S,\mathsf{T}}(x) \in K_{S,\mathsf{T}}(1)$ with $x \in B$, $x \in \mathrm{Int}^{\mathsf{T}}(S)$. Then $x \in K(S)$ by Lemma 4.2(b), $s = \mathrm{red}_S(x^{-1})$ lies in $\overline{B}^S$, and $xk_s \in K_g(S)$, so $z\,\mathrm{loc}_{S,\mathsf{T}}(k_s) \in \mathrm{K}^\circ(\mathcal{L})$ by Lemma 4.2(c). Summing the measures gives the claim. □

LEAN `Filling.IsFillingLevel.card_reducedImage_mul`

Corollary 4.6 (the reduction of the Bessel subgroup)**.** *In Setting 2.1, suppose that E carries Weil data, and write $\mathcal{S} = \mathcal{S}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, $\mathcal{H} = \mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$. Then $\#\overline{\mathcal{S}}^S = \#\overline{\mathcal{H}}^S \cdot \mathrm{uo}(S)$.*

Proof. By Theorem C(ii), for $\mathsf{T}_0 = \emptyset$, and Theorem C(i) there are a set T off which $\hat{g}(S)^{-1}$ is integral and a filling level $\mathcal{L}$ for S at T. Apply Proposition 4.5 to $B = \mathcal{U} = \mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and $\mu = \eta_{<\varrho}$: this measure is carried by the unipotent group at T, every element of which is the image of an element of $\mathcal{U}$ that is integral off T (Lemma 4.1), and it is invariant under right translation by that group (Input 3(b)). By the same input $\mu(\mathrm{K}^\circ(\mathcal{L})) = \mathsf{v}(\mathcal{L})$ and $\mu(K_{S,\mathsf{T}}(1)) = 1$. Hence $\#\overline{\mathcal{U}}^S \cdot \mathsf{v}(\mathcal{L}) = 1$, and $\#\overline{\mathcal{U}}^S = \mathrm{uo}(S)$ by Lemma 4.4(c). It remains to see that $(\bar{u}, \bar{h}) \mapsto \bar{u}\bar{h}$ is a bijection from $\overline{\mathcal{U}}^S \times \overline{\mathcal{H}}^S$ to $\overline{\mathcal{S}}^S$. It is injective because the two images meet in 1: if $u \in \mathcal{U} \cap K(S)$ and $h \in \mathcal{H} \cap K(S)$ have the same reduction, then $u^{-1}h \in K_g(S)$, so $h \in K_g(S)$ by Input 3(e). It is surjective because an element of $\mathcal{S} \cap K(S)$ is a product uh with $u \in \mathcal{U}$, $h \in \mathcal{H}$, and then $h \in K(S)$ by the same input, hence also $u \in K(S)$. □

LEAN `Filling.card_reducedImage_besselS`

5 The floor group, Weyl elements, and blocks as limits

Lemma 5.1 (positions of the elements of the floor group)**.** *In Setting 2.1, let $\gamma_1 \in G_S(E)$ with $\gamma_1 \in \mathcal{H}_\varrho(T_S^{\mathrm{rat}}(E))$ and let c, c' be classes. Put $l = \mathrm{pos}_S(c, c'; \gamma_1)$, $t = Z_S(\gamma_1)_{\varrho\varrho}$, and let $\omega \in E^\kappa$ be the vector of the coefficients of $\gamma_1 z$ at the basis vectors of κ. Then:*

(i) $l \in \mathcal{H}_\varrho(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$;
(ii) $l\,z = \mathrm{tv}(\bar{\pi}(S), t, y_c^{-1}\omega)$, *with t and ω read in $\mathbb{A}_{E,f}$;*
(iii) $N(S) \cdot \omega^*\omega = t\bar{t} - N(S)^2$;
(iv) *for every sequence p of units of E, $\mathrm{pos}_S(c, c'; w_\varrho(p)\gamma_1) = w_\varrho(p) \cdot l$, where on the right p is read as a sequence of finite ideles.*

Proof. As γ_1 fixes all e_a and e_a^*, it preserves the span of κ and z; write $\gamma_1 z = \sum_j \omega_j x_j + \zeta z$. The form is the identity on κ and $-N(S)$ at z, so $t = h(z, \gamma_1 z) = -N(S)\zeta$, and $h(\gamma_1 z, \gamma_1 z) = h(z, z)$ reads $\omega^*\omega - N(S)\bar{\zeta}\zeta = -N(S)$; this gives (iii). (i) The elements

$h_S(c)$, $h_S(c')$ lie in $\mathcal{H}$ and $\mathrm{r}^f_S(\gamma_1)$ fixes all e_a, e^*_a, since the change to the lattice basis only concerns the middle. (ii) $h_S(c')$ fixes z, so $l\,z = h_S(c)^{-1}\mathrm{r}^f_S(\gamma_1)z$; in the rational basis this is the vector with the κ-part $y_c^{-1}\omega$ and the coefficient $\zeta = -(\bar\pi(S)\overline{\bar\pi(S)})^{-1}t$ at z, and written in the lattice basis it is the tail vector. (iv) The Weyl element only moves the vectors e_a, e^*_a; it commutes with the change of basis and with the elements that fix all e_a and e^*_a, such as $h_S(c)$ and $h_S(c')$. □

LEAN `Filling.termPosition_floorGroup_spec`

Lemma 5.2 (Weyl elements at infinity; tail vectors at T)**.** *In Setting 2.1:*

(a) *For $\gamma \in G_S(E)$, a sequence p of units of E and an infinite place τ of E, $\mathrm{r}^\infty_S(w_\varrho(p)\gamma)_\tau = w_\varrho(p^{(\tau)}) \cdot \mathrm{r}^\infty_S(\gamma)_\tau$, where $p^{(\tau)}$ is the sequence $a \mapsto \mathrm{fs}_S(\tau, a) \cdot (p_a)_\tau$, read as 1 at the indices where this number is not a unit.*

(b) *For a finite set T of finite places of E that is stable under complex conjugation, a finite adele t and $x \in \mathbb{A}^\kappa_{E,f}$: $\mathrm{tv}(\bar\pi(S)_\mathsf{T}, t_\mathsf{T}, x_\mathsf{T}) = \big(\mathrm{tv}(\bar\pi(S), t, x)\big)_\mathsf{T}$.*

Proof. (a) r^∞_S is a homomorphism, and at the place τ it conjugates the image of a matrix by the diagonal matrix of the basis scales. The Weyl element has the entries p_a and $\bar p_a^{-1}$ between e_a and e^*_a; conjugation multiplies p_a by the quotient of the two scales, which is the frame scale $\mathrm{fs}_S(\tau, a)$, a positive real number, and $\bar p_a^{-1}$ by its inverse. (b) Taking components at T is a homomorphism of rings with involution, and the tail vector is given by ring operations. □

LEAN `Filling.ratToInf_weylElem_mul` · `Filling.tailVector_evalPlaces`

Proof of Theorem B. Write $T = T^{\mathrm{rat}}_S(E)$ and $\mathcal{U} = \mathcal{U}(T)$, and let

$$\mathcal{B} = \mathrm{Tm}^{\mathrm{lk}}_S(\Lambda) \cap \mathrm{Tm}_S(c, s, c').$$

As the amplitude sum over $\mathrm{Tm}^{\mathrm{lk}}_S(\Lambda)$ is not zero, there is an element γ_0 of $\mathcal{B}$. By hypothesis its leading minors do not vanish, so by Input 3(a) we can write $\gamma_0 = v^{-1}\, w_\varrho(r)\gamma_1\, v'$ with $v, v' \in \mathcal{U}$, a sequence r of units and $\gamma_1 \in \mathcal{H}_\varrho(T)$. Let $t = h(z, \gamma_1 z) = Z_S(\gamma_1)_{\varrho\varrho}$. By Input 3(c) the last leading minor of $Z_S(\gamma_0)$ is $r_0 \cdots r_{\varrho-1} t$, so t is a unit; the term discriminant of γ_0 is $d\bar d(t\bar t - N(S)^2) \neq 0$; and $\Lambda = \mathrm{link}(\gamma_0) = \mathrm{link}(w_\varrho(p)\gamma_1)$ for every sequence p.

(i) By Lemma 5.1(iii), at an infinite place τ, $|t_\tau|^2 - N(S)^2 = N(S)\sum_j |(\omega_j)_\tau|^2 \geq 0$, and it is not zero because $t\bar t \neq N(S)^2$ in E. The element $k = \mathrm{pos}_S(c, c'; \gamma_0)$ lies in $K(S)$ and has the reduction s, as $\gamma_0 \in \mathrm{Tm}_S(c, s, c')$.

(ii) For $p\colon \{0, \dots, \varrho - 1\} \to E^\times$ and $u, u' \in \mathcal{U}$ put $\gamma_{p,u,u'} = u\, w_\varrho((p \mid t))\gamma_1\, u'^{-1}$. The map $(p, u, u') \mapsto \gamma_{p,u,u'}$ is injective by Input 3(b). Its values lie in $\mathrm{Tm}^{\mathrm{lk}}_S(\Lambda)$: the link is Λ, and the term discriminant is $d\bar d(t\bar t - N(S)^2) \neq 0$ with $d = p_0 \cdots p_{\varrho-1}$ (Input 3(c)). Every $\gamma \in \mathcal{B}$ is a value: by Input 3(a), $\gamma = w^{-1} w_\varrho(q)\gamma_2 w'$ with $\gamma_2 \in \mathcal{H}_\varrho(T)$, and $\mathrm{link}(w_\varrho(q)\gamma_2) = \Lambda = \mathrm{link}(w_\varrho(1)\gamma_1)$ forces $\gamma_2 = \gamma_1$. Therefore the family $\mathbf{1}[\gamma_{p,u,u'} \in \mathrm{Tm}_S(c, s, c')] \cdot a^\sigma_S(c, c'; \gamma_{p,u,u'})$, indexed by the triples, is a reindexing of the summable family of the amplitudes over $\mathcal{B}$ (Input 3(c)), completed by zeros. Its sum is the amplitude sum of the theorem, and summing first over (u, u') gives a summable family

$$L_p = \sum_{(u,u')} \mathbf{1}\big[\gamma_{p,u,u'} \in \mathrm{Tm}_S(c, s, c')\big] \cdot a^\sigma_S(c, c'; \gamma_{p,u,u'})$$

with the same sum. The coset amplitude $a^\sigma_{S,\mathsf{T}}(c, s, c'; w_\varrho((p \mid t))\gamma_1)$ is the same sum with the further factor $\mathbf{1}[\mathrm{pos}_S(c, c; u) \in \mathrm{Int}^{\mathsf{T}}(S)]$. For each (u, u') this factor is 1 for

all sufficiently large T (Theorem C(iii)), and the terms are dominated by the norms of a summable family; by dominated convergence for series the coset amplitudes tend to L_p. $\square$

6 The unfolding

Proof of Theorem A. Write $G_{\mathsf{T}} = G(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$, $g = g_{\mathcal{L}}$, $\mathcal{U} = \mathcal{U}(T_S^{\mathrm{rat}}(E))$, $s = \mathrm{red}_S(k)$ and $P = \mathrm{pos}_S(c, c'; \gamma)$, which is integral off T; for $u, u' \in \mathcal{U}$ put $\gamma_{u,u'} = u\gamma u'^{-1}$.

Step 1: the left side. By Lemma 5.1(iv), $\mathrm{loc}_{S,\mathsf{T}}(P) = w_{\varrho}(p_{\mathsf{T}}) \cdot l_0$ with $l_0 = \mathrm{loc}_{S,\mathsf{T}}(\mathrm{pos}_S(c, c'; \gamma_1))$, so that $\mathcal{J}(Z; p_{\mathsf{T}}, l_0^{-1}) = \mathsf{h}_{\varrho}(\mathcal{L}; p_{\mathsf{T}}, 1) \cdot \mathrm{J}(\mathsf{M}(\mathcal{L}), W_Z(\cdot); \mathrm{loc}_{S,\mathsf{T}}(P))$. Its coordinate at (a, b) is the head density times

$$\int \chi_g(z\, a_a^{-1})\, \overline{\chi_g(\mathrm{loc}_{S,\mathsf{T}}(P)^{-1} z\, a_b^{-1})}\, d\mathsf{M}(\mathcal{L})(z) = \int \chi_g(z)\, \overline{\chi_g(\mathrm{loc}_{S,\mathsf{T}}(P)^{-1} z\, \mathrm{loc}_{S,\mathsf{T}}(k))}\, d\mathsf{M}(\mathcal{L})(z),$$

by the right invariance of $\mathsf{M}(\mathcal{L})$ (substitute $z\, a_a$ for z), the hypothesis $a_a a_b^{-1} \in \mathrm{loc}_{S,\mathsf{T}}(k)\, \mathrm{K}^\circ(\mathcal{L})$ and Input 3(a). The archimedean factor is $\mathrm{J}(dy, W^\sigma; \mathrm{r}_S^\infty(\gamma)) = \int \mathrm{bk}_S^\sigma(\gamma, y)\, dy$. So the left side of the theorem is $\mathsf{h}_{\varrho}(\mathcal{L}; p_{\mathsf{T}}, 1)$ times the integral over (z, y) of

$$\mathsf{r}(z, y) = \chi_g(z) \cdot \overline{\chi_g(\mathrm{loc}_{S,\mathsf{T}}(P)^{-1} z\, \mathrm{loc}_{S,\mathsf{T}}(k))} \cdot \mathrm{bk}_S^\sigma(\gamma, y). \tag{1}$$

Step 2: the right side. For (u, u') let $Q(u, u')$ be the condition of Definition 2.5: $\mathrm{pos}_S(c, c; u) \in \mathrm{Int}^{\mathsf{T}}(S)$ and $\gamma_{u,u'} \in \mathrm{Tm}_S(c, s, c')$. By the left invariance of $\mathsf{M}(\mathcal{L})$ and of dy, for every (u, u'),

$$\mathsf{M}(\mathcal{L})(\mathrm{K}^\circ(\mathcal{L})) \cdot a_S^\sigma(c, c'; \gamma_{u,u'}) = \int\!\!\int \mathbf{1}\big[\mathrm{loc}_{S,\mathsf{T}}(\mathrm{pos}_S(c, c; u))\, z \in \mathrm{K}^\circ(\mathcal{L})\big] \cdot \mathsf{a}_{u,u'}(\mathrm{r}_S^\infty(u)\, y)\, d\mathsf{M}(\mathcal{L})(z)\, dy,$$

where $\mathsf{a}_{u,u'}(y) = \beta_{S,c}(y)\, \beta_{S,c'}(\mathrm{r}_S^\infty(\gamma_{u,u'})^{-1} y)\, \mathrm{bk}_S^\sigma(\gamma_{u,u'}, y)$ is the integrand of the amplitude. The sum over the (u, u') with $Q(u, u')$ may be taken under the integral: the integral of the norm of the term of (u, u') is at most $\mathsf{M}(\mathcal{L})(K_{S,\mathsf{T}}(1)) \cdot |a|_S^\sigma(c, c'; \gamma_{u,u'})$, the map $(u, u') \mapsto \gamma_{u,u'}$ is injective (Input 3(b)), and the sum of these numbers over $\mathrm{Tm}_S(c, s, c')$ is finite (Input 3(c); the measure is finite by Input 3(b)). So it suffices to show, for all z and y,

$$\sum_{(u,u')} \mathbf{1}[Q(u, u')] \cdot \mathbf{1}\big[\mathrm{loc}_{S,\mathsf{T}}(\mathrm{pos}_S(c, c; u))\, z \in \mathrm{K}^\circ(\mathcal{L})\big] \cdot \mathsf{a}_{u,u'}(\mathrm{r}_S^\infty(u)\, y) = \mathsf{r}(z, y). \tag{2}$$

Step 3: the two conditions. Fix z and y. By Lemma 4.1, $z = \mathrm{loc}_{S,\mathsf{T}}(x)$ with $x \in \mathrm{Int}^{\mathsf{T}}(S)$. Put $\xi = P^{-1} x k$; it is integral off T (Lemma 4.2(b) for k), and $\mathrm{loc}_{S,\mathsf{T}}(\xi) = \mathrm{loc}_{S,\mathsf{T}}(P)^{-1} z\, \mathrm{loc}_{S,\mathsf{T}}(k)$. We claim that, for $u, u' \in \mathcal{U}$,

$$\begin{aligned} & Q(u, u') \text{ and } \mathrm{loc}_{S,\mathsf{T}}(\mathrm{pos}_S(c, c; u))\, z \in \mathrm{K}^\circ(\mathcal{L}) \\ \iff\quad & \mathrm{pos}_S(c, c; u)\, x \in K_g(S) \text{ and } \mathrm{pos}_S(c', c'; u')\, \xi \in K_g(S). \end{aligned} \tag{3}$$

By Lemma 4.2(c), and since x is integral off T, the element $l_1 = \mathrm{pos}_S(c, c; u)\, x$ lies in $K_g(S)$ exactly if $\mathrm{pos}_S(c, c; u)$ is integral off T and $\mathrm{loc}_{S,\mathsf{T}}(\mathrm{pos}_S(c, c; u))\, z \in \mathrm{K}^\circ(\mathcal{L})$. Suppose this. From $P = x k \xi^{-1}$ we get

$$\mathrm{pos}_S(c, c'; \gamma_{u,u'}) = \mathrm{pos}_S(c, c; u) \cdot P \cdot \mathrm{pos}_S(c', c'; u')^{-1} = l_1 \cdot k \cdot \big(\mathrm{pos}_S(c', c'; u')\, \xi\big)^{-1}.$$

As $l_1 \in K_g(S)$ and $k \in K(S)$ has the reduction s, the left side lies in $K(S)$ with the reduction s exactly if $\mathrm{pos}_S(c', c'; u')\,\xi \in K_g(S)$. This proves (3).

Step 4: phases. Let $u \in \mathcal{U}$ with $\mathrm{pos}_S(c, c; u)\,x \in K_g(S)$. Then

$$\chi_g(z) = \psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u))^{-1}. \tag{4}$$

Indeed $u_1 = \mathrm{pos}_S(c, c; u)$ lies in $\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and is integral off T (Input 3(c), Step 3); by Lemma 4.2(c), $\mathrm{loc}_{S,\mathsf{T}}(u_1)\,z \in \mathrm{K}^\circ(\mathcal{L})$, so by Input 3(a) and Lemma 4.3 $\chi_g(z) = \psi_{\mathsf{T}}(g^{-1}\,\mathrm{sd}(\mathrm{loc}_{S,\mathsf{T}}(u_1)^{-1})) = \psi_S^{\mathcal{U}}(u_1)^{-1}$; and $\psi_S^{\mathcal{U}}(u_1) = \psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u))$ by Input 3(c), because $u_1 = h_S(c)^{-1}\mathrm{r}_S^f(u)h_S(c)$. The same holds for u', c' and ξ. With Input 3(b) and the definition of the cutoffs' arguments, for (u, u') satisfying (3) the term of (2) is

$$\begin{aligned}&\beta_{S,c}(\mathrm{r}_S^\infty(u)y)\cdot\beta_{S,c'}(\mathrm{r}_S^\infty(u')\mathrm{r}_S^\infty(\gamma)^{-1}y)\cdot\psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u))^{-1}\psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u'))\cdot\mathrm{bk}_S^\sigma(\gamma,y)\\ &\quad=\beta_{S,c}(\mathrm{r}_S^\infty(u)y)\cdot\beta_{S,c'}(\mathrm{r}_S^\infty(u')\mathrm{r}_S^\infty(\gamma)^{-1}y)\cdot\mathsf{r}(z,y),\end{aligned}$$

by (4) for (u, x) and for (u', ξ), the values of $\psi_S^{\mathcal{U}}(\cdot)$ being of modulus 1.

Step 5: the cutoffs sum to one. So the left side of (2) is $\mathsf{r}(z, y)$ times the product of

$$\Sigma_c(x, y) = \sum_{u \in \mathcal{U}} \mathbf{1}[\mathrm{pos}_S(c, c; u)\,x \in K_g(S)] \cdot \beta_{S,c}(\mathrm{r}_S^\infty(u)\,y)$$

and of $\Sigma_{c'}(\xi, \mathrm{r}_S^\infty(\gamma)^{-1}y)$. If $\mathsf{r}(z, y) = 0$ we are done. Otherwise $\chi_g(z) \neq 0$ and $\chi_g(\mathrm{loc}_{S,\mathsf{T}}(\xi)) \neq 0$, and it suffices to show: if x is integral off T and $\chi_g(\mathrm{loc}_{S,\mathsf{T}}(x)) \neq 0$, then $\Sigma_c(x, y) = 1$ for all y. By Input 3(a) and Lemma 4.1 there is $u_2 \in \mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, integral off T, with $\mathrm{loc}_{S,\mathsf{T}}(u_2^{-1}x) \in \mathrm{K}^\circ(\mathcal{L})$, hence $u_2^{-1}x \in K_g(S)$ (Lemma 4.2(c)). By Input 3(d) there is a rational $v \in \mathcal{U}$ with $u_2^{-1}\mathrm{pos}_S(c, c; v) \in K_g(S)$. Then, for $u \in \mathcal{U}$, $\mathrm{pos}_S(c, c; u)\,x \in K_g(S)$ exactly if $\mathrm{pos}_S(c, c; uv) \in K_g(S)$, that is, $uv \in \mathcal{U}_{S,c}$; so with $u = wv^{-1}$,

$$\Sigma_c(x, y) = \sum_{w \in \mathcal{U}_{S,c}} \beta_{S,c}(\mathrm{r}_S^\infty(w)\,\mathrm{r}_S^\infty(v)^{-1}y) = 1$$

by the partition of unity of Input 3(a). This proves (2) and the theorem. □

7 The filling data of the admissible data

Definition 7.1 (the filling data of D)**.** In Setting 2.6, the *filling data of* D, $S(D)$, are the filling data over $E(D)$ of the shape $\mathfrak{s}(D)$ with the following components: the number $b(D)$; the prime $N(D)$ and the idele $\hat{\pi}(D)$; the primes $g_0(D)$, $g_1(D)$ with the chosen places of D above them; the generator $\varpi(P)$ of the different; the column level $K_0^{\mathrm{col}}(D)$; and at every infinite place τ a Bessel system chosen among those of Proposition 7.3. The conditions on filling data (Setting 2.1) hold by Input 3(a), (b). In particular $b(S(D)) = b(D)$, $N(S(D)) = N(D)$, $g(S(D)) = g_0(D)g_1(D)$, and for the shape $\mathfrak{s} = \mathfrak{s}(D)$: $\varrho(\mathfrak{s}) = \varrho(D)$, $k(\mathfrak{s}) = k(D)$ and $r(\mathfrak{s}) = 2\varrho(D) + k(D) + 1 = r(D)$.

LEAN `Data.filling`

Lemma 7.2 (three small facts)**.** *In Setting 2.6: the index set $X_0(D)$ of the columns has $k(D)$ elements. Moreover the formal text fixes, as instances, a unitary matrix that diagonalises the real form of the shape $\mathfrak{s}(D)$ with the signs of the space of the rows (a* frame*), and records the bound $b(D)^{10} \leq 2^{\varrho(D)}$.*

Proof. The first is the count of the index set in the unit on the seesaw. The frame exists because the form has as many negative signs as the standard form of these signs, and one is chosen. The bound is one of the logarithmic bounds of Chapter III: $10 \log b(D) \le \varrho(D) \log 2$. □

LEAN `Data.card_X₀` · `Data.unitarySignFrameY` · `Data.instLbHPowRealNatOfNatgHMulLb`

Proposition 7.3 (Bessel systems for the data)**.** *In Setting 2.6, let τ be an infinite place of $E(D)$. Then there is a Bessel system $\mathfrak{B}$ on the real group $G_1(\mathfrak{s}(D))$, for the bound $b(D)$ and the number $f(D)$ in the sense of the set-up, of the type $\mathfrak{B} \in \mathrm{Bes}(2\varkappa_D(\tau,\cdot), \mathsf{w}_D^{\mathrm{col}}(\tau))$, which means:*

(i) *the degree of $\mathfrak{B}$ is the value of Weyl's dimension polynomial at the doubled row parameter $2\varkappa_D(\tau,\cdot)$;*

(ii) *there is an invertible matrix A such that, for every h in the unitary group of the columns, embedded as the subgroup that fixes the frame and its dual, and every point y, the full Bessel function satisfies $A\,W^{\mathrm{full}}(hy) = \mathrm{Sch}(h)\,A\,W^{\mathrm{full}}(y)$, where* Sch *is the transpose of the Schur representation of weight $\mathsf{w}_D^{\mathrm{col}}(\tau)$ at the transposed element; and*

(iii) *W^{full} is fixed by right convolution with the kernel of the discrete series of the parameter $2\varkappa_D(\tau,\cdot)$, read in the frame of Lemma 7.2.*

Proof. An assembly of Input 3(d); its content lies there. The steps, in the order of the formal text: (1) the doubled row parameter λ has entries of absolute value at most $3a(D)$ and a gap of size $r(D)^7$ (Chapter III), and its lowest type for the maximal compact subgroup is the column weight at one position and 0 at the others. (2) The formal degree of λ is positive and equals Weyl's dimension polynomial; the kernel of its discrete series in the frame is idempotent; and the parameter is steep in the sense of the unit on the exchange. (3) The Gram matrix of the Weyl module of the column weight is positive definite, of the form B^*B; conjugating the Schur representation by B gives a unitary representation ρ, and a matrix that commutes with it is scalar. (4) There is a Bessel function of type ρ whose matrix coefficient is that of the lowest type, with the bounds of the Laplace method. (5) It has a cut pair, whose full function satisfies the Schur bounds. (6) The cut function has band limits; the constant that this requires is bounded as follows: each factor $|\lambda_i - \lambda_j|/2$ of Weyl's polynomial is at most $3a(D)$, since both entries are at most $3a(D)$ in absolute value, and the remaining factorials and powers are compared with powers of $b(D)$ by the bounds of Chapter III. These data form a Bessel system; (i) holds by (2), (ii) with $A = B^*$ by (3), and (iii) by the convolution identity of the cut pair and the idempotent kernel. □

LEAN `Data.exists_besselSystem`

Proof of Theorem D. Write $S = S(D)$, $N = N(D)$, $k = k(D)$, $f = f(D)$.

(i) By Input 3(c), $\mathrm{inc}_S^{-1}(K_g(S))$ is the group of the $y \in K_f$ whose row at k_0 is congruent to that of the identity modulo every place dividing $\hat{\pi}(D)$, and whose reduction at every chosen place is 1. By Input 3(b) this is the description of $K_0^{\mathrm{col}}(D)$.

(ii) By Input 3(c), $\mathrm{inc}_S^{-1}(K(S)) \cap K_f$ is the group of the $y \in K_f$ such that, for each of the f places w dividing $\hat{\pi}(D)$, the inverse transpose of the reduction of y at w fixes the basis vector of k_0 in $\mathbb{F}_w^k$. No two of these places are conjugate, so the reduction

maps K_f onto the product of the groups $\mathrm{GL}_k(\mathbb{F}_w)$, and the index is the product of the indices of the stabilisers of a non-zero vector, each equal to N^k-1 (Input 3(e)).

(iii) The class automorphism groups of the column level are trivial, so $\#\mathrm{Cl}(S)$ is its class sum, which is $[K_f : K_0^{\mathrm{col}}(D)] \cdot \mathrm{mass}(E(D),k)$ (Input 3(b)). By (i) the index is

$$[K_f : \mathrm{inc}_S^{-1}(K(S)) \cap K_f] \cdot [\mathrm{inc}_S^{-1}(K(S)) : \mathrm{inc}_S^{-1}(K_g(S))] = (N^k-1)^f \cdot \#\overline{\mathcal{H}}^S,$$

by (ii), and because inc_S maps onto $\mathcal{H}$, so that the second index is the order of the image of $\mathcal{H} \cap K(S)$ under red_S.

(iv) The standing hypotheses are: (1) $K^{\mathrm{col}}(S) = \mathrm{inc}_S^{-1}(K_g(S))$; (2) red_S is surjective; (3) $|\varpi(S)_\tau| \le b(S)$ and $1 \le |\kappa_\tau(S)| \le b(S)^{23}$ for all τ, and $N(S) \le b(S)^{60n(\mathfrak{s})}$; (4) the band inequality $\prod_\tau c_{\mathrm{band}}(\mathfrak{s})\, b(S)^{7k(\mathfrak{s})} \left(|\kappa_\tau(S)|^{2\varrho(\mathfrak{s})+1}/(g(S)N(S))\right)^{k(\mathfrak{s})-n(\mathfrak{s})^7} \le \deg(S)^{-1}$; (5) $\mathrm{tl}(S)^{44}\mathtt{d}_1(S) \le \mathtt{d}(S)$, $\mathrm{tl}(S)^{18}\mathrm{cf}(S)\mathtt{d}(S) \le \mathtt{d}_1(S)$ and $\mathrm{cf}(S) \le 1$; (6) $\#\mathrm{Bc}(S) \le b(S)^{2k(\mathfrak{s})f(E)}$; (7) $(N(S)^{k(\mathfrak{s})}/b(S))^{f(E)}$ is at most the index of (ii); and (8) the bound for the packet constant $a_*(S)$ stated in Note F. Here $\kappa_\tau(S)$, $c_{\mathrm{band}}(\mathfrak{s})$, $\deg(S)$, $\mathrm{tl}(S)$, $\mathtt{d}_1(S)$, $\mathtt{d}(S)$, $\mathrm{cf}(S)$ are the constants of the set-up, as recalled in Note F. (1) is (i), and (2) is Input 3(c). The others are inequalities between positive real numbers. The formal proof makes every quantity explicit: $\#\overline{\mathcal{S}}^S = \#\overline{\mathcal{H}}^S \cdot \mathrm{uo}(S)$ (Corollary 4.6), $\#\mathrm{Cl}(S)$ by (iii), the index by (ii), $\prod_\tau |\varpi(S)_\tau|$ as a power of the root discriminant, the volumes and the covolume by their definitions, and $r(\mathfrak{s}) = k + 2\varrho(D) + 1$. It then takes logarithms; with the bounds for $\#\mathrm{Bc}(S)$, for $\log\deg(S)$ and for the ratios of the masses of the ranks from k to $r(D)$ (Input 3(e)), with $N \le N^k$ and $k\log N - 2/N \le \log(N^k-1)$, each inequality becomes a linear inequality between the logarithmic sizes of the data, which follows from the windows of Chapter III (Input 3(a)). This linear arithmetic is not reproduced here. □

Lemma 7.4 (an expansion of a product of stacked determinants)**.** *In Setting 2.6, with the notation of the note* The height of a ratio of lift volumes*: let j be a lift index, i a line choice with its short rows Y_i, and let Δ be the product of the stacked determinants of the matrices $\mathrm{dr}_D(j,i,Y_i,\tau)$ along $\mathrm{pe}_D(j)$, a polynomial in variables $x_{\tau,a,b}$ with τ an infinite place, $a < 2m(D)$, and b either a number below $k(D)+j-1$ or an index of the space L^+. Let n be a set, f a map from the row indices to n and g a map from the indices of L^+ to n. Let $\Delta^{f,g}$ be the image of Δ under the substitution $x_{\tau,a,b} \mapsto x_{\tau,a,f(\mathrm{bv}_D(b))}$ for the numbers b and $x_{\tau,a,b} \mapsto x_{\tau,a,g(b)}$ for the indices of L^+. Then*

$$\Delta^{f,g} = \sum_l f_*(P_l) \cdot g_*(\mathrm{lc}_D(j,i,Y_i)_l),$$

where l runs over the index set of the basis of the Weyl module of the weight of the first columns, P_l is the letter polynomial *of the l-th basis vector for the positive letters (its polynomial, with the variable of (τ,a) and of the number h replaced by the sum of the variables $x_{\tau,a,i'}$ over the row indices i' of positive sign and of order h, for the order function of the untwisted auxiliary pair), and f_*, g_* rename the last index of the variables.*

Proof. By Input 3(f) and the linearity of the polynomial of a vector, Δ, read as a polynomial in the first columns with coefficients in the variables of L^+, is $\sum_l p_l \cdot \mathrm{lc}_D(j,i,Y_i)_l$ with p_l the polynomial of the l-th basis vector. The substitution of the statement and the map that sends p_l to $f_*(P_l)$ and renames the coefficients by g are homomorphisms of algebras, so it suffices to compare them on the variables. On

a variable of L^{+} both are g_{*}. On the variable of (τ, a) and a number h, the second gives the sum of the $x_{\tau,a,f(i')}$ over the row indices i' of positive sign and order h; there is exactly one such index, $i' = \mathrm{bv}_{D}(h)$, because the order of such an index is its number, the numbering of the row indices is a bijection, and the sign is positive exactly for the numbers below $k(D) + j - 1$. □

LEAN `Data.stdClassSum_carrierXi_eq_lineMultiplier`

8 Where the results are used

Note F (*Translates of Poincaré series fill the rows*) quotes Theorem C as its Input 4(a); Lemma 4.1, Lemma 4.2, Lemma 4.3 and Lemma 4.4 as Input 4(b); Proposition 4.5 and Corollary 4.6 as Input 4(c); Lemma 5.1 and Lemma 5.2 as Input 4(d); Theorem B as Input 4(e); Theorem A as Input 4(f); and Definition 7.1, Proposition 7.3 and Theorem D as Input 9(a). Outside this unit, Proposition 7.3 is used in the unit on the seesaw, where the filling data are shown to fit the space of the rows (the module on generic Bessel functions), and Theorem D(i) in the seesaw theorem. Lemma 7.4 is used in the unit on the rows, in the module on the separation of the lines. Theorem D(ii), (iii) and Corollary 4.6 are used in the proof of Theorem D(iv).

9 Notes on the formal text

1. *Arguments that the census reads differently from Lean; to be settled by* `#check` *on a build.* In the three statements of Theorem C(ii), (iii) the set T is bound by "for all sufficiently large" or "there are arbitrarily large"; the census lists it as an argument, with its stability under conjugation, because a variable of the file has this name. The same holds for the stability of T in Theorem B and Corollary 4.6, where T is bound or absent. For Lemma 4.4(c) the census lists no hypothesis although the statement names the level; the note states the setting that Lean takes.
2. *Statements cut by the census.* The statements of Lemma 5.1 and of Theorem A contain local definitions at which the census ends the statement; they were read to their true end, with the second reader's table of corrected spans.
3. *The side.* The side is an instance argument of the coset amplitude and of Theorems A and B, with the full side as default instance; the note writes it as the superscript σ.
4. *Forms of the formal statements.* In Theorem A the two sides are written with scalar multiplications, and the measure of the congruence subgroup is taken as a real number. In Theorem B the family is indexed by the maps from $\{0, \dots, \varrho - 1\}$, the element k is given as an element of $K(S)$, and the limit is along all finite sets of finite places, not only the stable ones. In Definition 2.3 the index set of the orthonormal part and the number of further pairs are fixed by the type of the level. In Lemma 4.4(b) the right side is written as the square of the inverse of $g(S)^{f(E)}$.
5. *A hypothesis stronger than its use.* Proposition 4.5 assumes the invariance of μ under the images of all elements of B; the proof uses it only for the representatives $k_{s} \in B \cap K(S)$, which are integral. A statement with invariance only under the images of the elements of B that are integral off T is true by the same proof, but

it is not the formal one. Note F quotes the formal hypothesis in its Input 4(c), and its one application (to $B = \mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and to the measure of the level on the group $\mathcal{H}(T_S^{\mathrm{lat}}(E_{\mathsf{T}}))$) satisfies it.

6. *Definition 7.1.* The formal definition gives several components of the filling data only through the proofs of their properties; they were read off these proofs. The identification of the group $\mathsf{G}(S(D))$ with $\mathsf{G}(D)$, used in Note F, is not a statement of the modules of this note.
7. *Lemma 7.4.* Its formal name speaks of a class sum and a line multiplier; the statement is the polynomial identity given here, and the class sums appear where it is used.
8. *Points where the dossier's first reading was corrected by the second reader.* In Lemma 4.4(a) the summary of the proof gave the wrong power of the index; the statement is as above. In the proof of Theorem C(i) the self-duality is the statement about the annihilator of O_{T}, with the quantifier over r. In Proposition 7.3 the bound $3a(D)$ holds for each entry of the parameter (so $6a(D)$ for a difference, before the division by 2). In Theorem D(iv) the elementary fact used is $N \le N^k$.
9. *What was not re-derived.* The linear arithmetic of Theorem D(iv); the constructions behind Proposition 7.3; the axioms of a place structure in Theorem C(i) other than the self-duality; in Lemma 7.4, that the order of a row index of positive sign is its number, which is taken from the last step of the formal proof. The measurability and summability conditions of the interchange of sum and integral in Theorem A are verified in the formal text; the text above gives the bound that is used.

How this note was written. From the structured proofs of the three modules in the third chunk of the unit's dossier, all of whose statements and claims a second reader had re-read; her remarks were taken into account. I read the three modules in the Lean text line by line and compared every statement of this note with it argument by argument; I read in the Lean text the definitions of the filling data, of admissibility, of Bessel systems and their type, of the character at T, and of the notions of the unit on the rows that Lemma 7.4 needs. The inputs are stated from the dossier's readings of their quoted statements. Arguments that are mine and shorter than the formal ones: the proof of Lemma 4.1 by the identity for $x^{*}Jx - J$, the proof of Lemma 5.1 in coordinates, and the organisation of the proof of Theorem A in five steps. Nothing was compiled for this note. The program check of the unit's dossier covered 1371 leaf steps of 179 proofs.

Appendix A. Concordance with the Lean artifact

The formal names of the objects and the letters of this note: `IsIntegralOff`, `toPlaces`, `IsFillingLevel`, `cosetAmplitude` are $x \in \mathrm{Int}^{\mathsf{T}}(S)$, $\mathrm{loc}_{S,\mathsf{T}}$, $\mathcal{L} \in \mathrm{FL}(S,\mathsf{T})$, $a^{\sigma}_{S,\mathsf{T}}(c,s,c';\gamma)$; `Data.filling` is $S(D)$; `LocProd`, `evalPlaces`, `adeleOfLocal`, `integralOff` are E_{T}, $x \mapsto x_{\mathsf{T}}$, $y \mapsto \tilde{y}$, integrality off T; `unitaryLevel` is $\hat{K}_S(u)$ over the finite adeles and $K_{S,\mathsf{T}}(u)$ over E_{T}; `latStabilizer`, `principalLevel`, `reduction`, `reducedImage` are $K(S)$, $K_g(S)$, red_S, $\overline{B}^{S}$; `termPosition`, `termsOver`, `termsOfLink` are $\mathrm{pos}_S(c,c';\gamma)$, $\mathrm{Tm}_S(c,s,c')$, $\mathrm{Tm}^{\mathrm{lk}}_S(\Lambda)$; `selfDualChar`, `charOnPlaces`, `unipotentChar` are ψ_S, $\psi_{S,\mathsf{T}}$, $\psi^{\mathcal{U}}_S(u)$; `besselKernel`, `classCutoff`, `amplitude`, `amplitudeSum` are

$\mathrm{bk}^{\sigma}_{S}(\gamma, y)$, $\beta_{S,c}$, $a^{\sigma}_{S}(c, c'; \gamma)$, $A^{\sigma}_{S}(\Xi; c, s, c')$; `unipOrder`, `unipotentMass`, `frameScaleSq` are $\mathrm{uo}(S)$, $\mathsf{v}(\mathcal{L})$, $\mathrm{fs}_{S}(\tau, a)$; `padTuple`, `tailVector`, `weylElem` are $(p \,|\, t)$, $\mathrm{tv}(\pi, t, x)$, $w_{\varrho}(p)$; the element `σ` of the formal statements is γ_1, the set `T` is T, the level `F` is $\mathcal{L}$; `paramW` and `Data.κ` are the doubled row parameter and the column weight. Two statements as the artifact has them:

Notation

E, $x \mapsto \bar{x}$, τ, v, x_τ, $f(E)$ a CM field with its CM type, conjugation, infinite places, the image at a place, their number

w, $\bar{w}$, $\mathbb{F}_w$, E_w, O_w, $\mathbb{A}_{E,f}$, $\hat{O}_E$, ψ_f a finite place, its conjugate, residue field, completion, integers; finite adeles, integral adeles, the standard character

T, T_0, T', E_T, O_T, x_T, $\tilde{y}$ finite sets of places (of units for T_0), the product of completions, its integers, components, extension by zero

ψ_T, mod_T, $[u]$, δ, τ_0, β, A character, modulus, generalised index, a skew unit, a trace-one element and skew elements of the place structure on $A = E_\mathsf{T}$

$\mathfrak{s} = (\varrho, \kappa, k_0)$, $\varrho(\mathfrak{s})$, $k(\mathfrak{s})$, $n(\mathfrak{s})$, $r(\mathfrak{s})$ a shape and its numbers; in proofs ϱ abbreviates $\varrho(\mathfrak{s})$

$I(\mathfrak{s})$, e_a, e_a^*, z, x_j, $\mathfrak{f}_a$, h index set, basis vectors, the frame, the hermitian form

T, $J(T)$, $G(T)$, $Z_T(x)$, $\mathcal{U}(T)$, $\mathcal{H}(T)$, $\mathcal{S}(T)$, $\mathcal{H}_\varrho(T)$ a form, split Gram matrix, unitary group, frame Gram matrix, Bessel unipotent subgroup, the subgroup fixing the frame and its dual, Bessel subgroup, floor group; $\mathcal{U}$, $\mathcal{H}$, $\mathcal{S}$ in proofs

$\mathrm{sd}(u)$, $w_\varrho(p)$, $(p \,|\, t)$, $\mathrm{tv}(\pi, t, x)$ sum above the diagonal, Weyl element, padded sequence, tail vector

S, $b(S)$, $N(S)$, $\bar{\pi}(S)$, $q_i(S)$, $g(S)$, $\mathrm{Ch}_i(S)$, $\varpi(S)$, $K^{\mathrm{col}}(S)$, $\mathfrak{B}_\tau(S)$ filling data and their components

$T_S^{\mathrm{rat}}(R)$, $T_S^{\mathrm{lat}}(R)$, $G_S(R)$, G_S^{lat}, $\Lambda(S)$, r_S^f, r_S^∞, inc_S, $\mathrm{fs}_S(\tau, a)$ forms, groups, the lattice basis, the maps to the finite adeles, to infinity and from the unitary group of the columns, frame scales

$\hat{K}_S(u)$, $K(S)$, $K_g(S)$, $\hat{g}(S)$, red_S, $\mathsf{G}(S)$, $\overline{B}^S$, $K_{S,\mathsf{T}}(u)$ level groups, the idele of g, reduction, the finite group, reduced image, level groups at T

ψ_S, $\psi_{S,\mathsf{T}}$, $\psi_S^{\mathcal{U}}(u)$, $\mathrm{uo}(S)$ characters, unipotent character, the order

$\mathrm{Cl}(S)$, c, c', y_c, $h_S(c)$, $\mathrm{pos}_S(c, c'; \gamma)$, $\mathrm{Tm}_S(c, s, c')$, $\mathcal{U}_{S,c}$ classes, representatives, positions, terms, the unipotent lattice of a class

$Z_S(\gamma)$, $\mathfrak{g}_S(\gamma)$, $\mathrm{link}(\gamma)$, Λ, $\mathrm{Tm}_S^{\mathrm{lk}}(\Lambda)$ frame Gram matrix, term discriminant, links, the terms of a link

$\mathrm{Bc}(S)$, σ, $W_S^\sigma(y)_i$, W^σ, $\mathrm{bk}_S^\sigma(\gamma, y)$, $\beta_{S,c}$, $a_S^\sigma(c, c'; \gamma)$, $|a|_S^\sigma(c, c'; \gamma)$, $A_S^\sigma(\Xi; c, s, c')$ Bessel coordinates, a side, Bessel functions, kernel, cutoffs, amplitudes, amplitude sums

$x \in \mathrm{Int}^{\mathsf{T}}(S)$, $\mathrm{loc}_{S,\mathsf{T}}$, $\mathcal{L} \in \mathrm{FL}(S, \mathsf{T})$, $a_{S,\mathsf{T}}^\sigma(c, s, c'; \gamma)$ integral off T, components at T, filling levels, coset amplitude

$\mathcal{L}$, $g_\mathcal{L}$, $\mathrm{K}^\circ(\mathcal{L})$, $\mathcal{L} \in \mathrm{StdLev}$, $\mathsf{M}(\mathcal{L})$, $\eta_{<j}$, $\mathsf{d}_l(\mathcal{L}; g)$, $\mathsf{v}(\mathcal{L})$, $\mathsf{h}_\varrho(\mathcal{L}; p, 1)$ a level, its unit, congruence subgroup, standard levels, group measure, Heisenberg measures, floor modulus, unipotent mass, head density

$\chi_g(y)$, $\mathrm{Int}(\mathcal{L})$, Z, $\mathrm{Cos}(Z)$, a_c, $W_Z(y)$, $\mathcal{J}(Z; p, l)$, $\mathrm{J}(\mu, W; \gamma)$ finite Bessel function, intermediate groups, cosets, representatives, finite Bessel vector, correlation, Bessel correlation

γ, γ_0, γ_1, γ_2, $\gamma_{u,u'}$, $\gamma_{p,u,u'}$, p, q, r, t, ω, ζ, d rational elements, sequences of units, the corner entry, the vector and coefficient of $\gamma_1 z$, a product

k, l, l_0, l_1, x, ξ, P, u, u', u_0, u_1, u_2, v', w', s, a, b, y elements of the level groups and adelic elements of the proofs, cosets, a point at infinity

L_p, $\mathcal{B}$, $Q(u, u')$, r, $\mathsf{a}_{u,u'}$, Σ_c, C_s, k_s, B, μ, J, e, G_T the limits, a block, the condition, integrands, sums of cutoffs, sets, representatives, a subgroup, a measure, a Gram matrix, a difference, the group at T

P, D, $E(D)$, $m(D)$, $r(D)$, $k(D)$, $\varrho(D)$, $f(D)$, $b(D)$, $a(D)$, $N(D)$, $\hat{\pi}(D)$, $\pi_N(D)$, $g_i(D)$, $\varpi(P)$, N_0 parameters, admissible data and their numbers

$X_0(D)$, $K_0^{\mathrm{col}}(D)$, $\mathfrak{s}(D)$, $\mathsf{G}(D)$, $S(D)$, K_f, $\varkappa_D$, $\mathsf{w}_D^{\mathrm{col}}$, λ index set and level of the columns, the shape, the finite group, the filling data, integral points, row parameter, column weight, the doubled parameter

$\mathfrak{B}$, $\mathfrak{B} \in \mathrm{Bes}(l, w)$, W^{full}, A, Sch, ρ, $G_1(\mathfrak{s})$ a Bessel system, its type, the full Bessel function, an intertwiner, the Schur representation, the real group

$\kappa_\tau(S)$, c_{band}, $\deg(S)$, $\mathrm{tl}(S)$, $\mathsf{d}_1(S)$, $\mathsf{d}(S)$, $\mathrm{cf}(S)$, $a_*(S)$, $\mathrm{mass}(E, r)$ constants of the set-up, the mass

Δ, $\Delta^{f,g}$, $x_{\tau,a,b}$, $\mathrm{bv}_D(b)$, $\mathrm{pe}_D(j)$, $\mathrm{dr}_D(j, i, Y, \tau)$, $\mathrm{lc}_D(j, i, Y)$, Y_i, L^+, P_l, p_l, f, g, n, j, i, i' the objects of Lemma 7.4

m, m', ι, n, ζ_A, $\zeta_{\hat{O}_E}$, $\ell^2(X)$, X, R, Ξ, N, K, F, O numbers of a level, zeta functions, $\mathbb{C}^X$, a ring, a set of rational elements, and letters in names

READBACK NOTE 39

Links of pairs of terms: integral lifts and the discriminant gain

One unit of the Lean artifact grh-compact, read back into mathematics

Summary. In the second moment of the Poincaré series, two rational terms γ, γ' over the same classes and the same element of the level group interact through their *links*, two Lagrangian subspaces of a split hermitian space of dimension $2(k(\mathfrak{s})+1)$. This note proves the arithmetic input for the pairs whose links differ: the product of the invariants of the pair, which measure the lattice of the common part of the links, is smaller than the product of the gauges of the two terms by a power of $2/g(S)$ for each dimension in which the links differ. The proof computes the discriminant of the lattice of integral lifts of a link by a bordered determinant and Jacobi's identity, splits this lattice orthogonally along the second link, and applies an inequality of Liouville type to the pairing of the two complements, which is divisible by $g(S)$ because the two terms are congruent.

What this note is. The artifact grh-compact is a body of Lean code: the compact edition of a formal proof, due to L. Alpöge with the AI system Claude, of the Riemann hypothesis and of its generalisation to Dirichlet L-functions. That headline is a claim. The authors report that every file compiles and that Lean's kernel accepted the proofs; an independent replay is recorded in the handout's record of checks when it reports. No mathematician has read the argument through, and nothing here says that the Riemann hypothesis is proved. This note (Note P of its unit) treats 9 of the 497 declarations of the unit *Translates of Poincaré series fill the rows*: the module on link pairings. Proved here from the inputs: Theorems A and B and the statements of §4; where a step is a verification of matrix entries, the note says so and gives the identity that is verified. Taken for granted and stated as Inputs 1 to 4: the properties of links, levels and class coordinates from the set-up of the unit, an inequality of Liouville type for Gram determinants, the bound of an index by agreeing characters, and Jacobi's identity for discriminants of complements from the background library. Every statement was compared with its Lean text, argument by argument. The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 9 declarations.

1 The statements

The objects are recalled in §2. In brief: $\mathrm{link}(\gamma)$ is the link of a rational element, $\mathrm{link}^{\circ}(\gamma,\gamma')$ the common part of two links inside E^{κ}; $\mathrm{pi}_S(c,c';\gamma,\gamma')$ is the invariant of the pair and $\mathrm{cg}_S(j;c,c';\gamma)$ the gauge of a term of level j.

Theorem A (the discriminant gain). *In Setting 2.1, suppose that E is stably unramified. Let c, c' be classes of S, $s \in \mathsf{G}(S)$ an element that agrees, x a natural number such that s fixes norm at least x, j a level, and $\gamma, \gamma' \in \mathrm{Tm}_S(c, s, c')$ two terms with $\gamma \in \mathrm{Lv}_j(S)$ and $\gamma' \in \mathrm{Lv}_j(S)$. Then there is a natural number i such that*

(i) $k(\mathfrak{s}) \le \dim_E \mathrm{link}^\circ(\gamma, \gamma') + i + (j - \varrho(\mathfrak{s}))_+$;
(ii) *if $i = 0$, then $\mathrm{link}(\gamma) = \mathrm{link}(\gamma')$; and*
(iii) *with $x' = x$ if $\varrho(\mathfrak{s}) < j$ and $i = 0$, and $x' = 1$ otherwise,*

$$\mathrm{pi}_S(c, c'; \gamma, \gamma') \cdot \mathrm{pi}_S(c, c'; \gamma', \gamma) \cdot x'^2 \le \Big(\frac{2}{g(S)}\Big)^{2\,i\,f(E)} \cdot \mathrm{cg}_S(j; c, c'; \gamma) \cdot \mathrm{cg}_S(j; c, c'; \gamma').$$

LEAN `Filling.pairInvariant_mul_le`

Theorem B (splitting a link along a second one). *In Setting 2.1, suppose that E is stably unramified. Let c, c' be classes of S, $s \in \mathsf{G}(S)$ an element that agrees, x a natural number such that s fixes norm at least x, j a level, $\gamma \in \mathrm{Tm}_S(c, s, c')$ a term with $\gamma \in \mathrm{Lv}_j(S)$, and $\gamma' \in G_S(E)$. Put $k_\gamma = \mathrm{pos}_S(c, c'; \gamma)$ and $L = \mathrm{link}(\gamma) \cap \mathrm{link}(\gamma')$. Then*

(i) $0 < \mathrm{disc}_{S,c}(\mathrm{link}^\circ(\gamma, \gamma'))$ *and* $1 \le \mathrm{o}_{S,c}(k_\gamma; 1, \mathrm{link}^\circ(\gamma, \gamma'))$;
(ii) *there are a natural number i, a finite index set $\mathcal{C}$, a matrix m over E with columns indexed by $\mathcal{C}$, a matrix y over E with i columns, $v \in \mathrm{GL}_i(\mathbb{A}_{E,f})$ and a matrix z over $\mathbb{A}_{E,f}$ with rows $\mathcal{C}$ and i columns, such that: $i = k(\mathfrak{s}) + 1 - \dim L$; $k(\mathfrak{s}) \le \dim \mathrm{link}^\circ(\gamma, \gamma') + i + (j - \varrho(\mathfrak{s}))_+$; if $i = 0$ then $L = \mathrm{link}(\gamma)$; the columns of m span L; the columns of y lie in $\mathrm{link}(\gamma)$; $yt \in L$ only for $t = 0$; the columns of $(m \mid y)$ span $\mathrm{link}(\gamma)$; $\tilde{m}z + \tilde{y}v \in \mathrm{IL}(c; \gamma)$; and, with x' as in Theorem A,*

$$\big(\mathrm{pi}_S(c, c'; \gamma, \gamma') \cdot x'\big)^2 \cdot \mathrm{ld}_S(y, v) \le \mathrm{cg}_S(j; c, c'; \gamma)^2.$$

LEAN `Filling.exists_link_split_le_classGauge`

Theorem A is used in the crude estimate of the unit (the note on the energy of amplitude sums): there the pairs of terms of one level over one (c, s, c') are summed with the weights that the invariants of the pair control, and the factor $(2/g(S))^{2if(E)}$ pays for the number of links at distance i.

2 The setting

Conventions. The natural numbers are $0, 1, 2, \dots$, and $(a)_+$ is a if $a \ge 0$ and 0 otherwise. E is a CM field with its CM type: a number field that is a CM field, with complex conjugation $x \mapsto \bar{x}$ and one embedding at each infinite place τ; x_τ is the image of x, $f(E)$ the number of infinite places, $N_{E/\mathbb{Q}}$ the norm. $\mathbb{A}_{E,f}$ is the ring of finite adeles, $\hat{O}_E$ its subring of integral adeles, $\tilde{a}$ the image in $\mathbb{A}_{E,f}$ of a matrix a over E, and $[\xi]$ the generalised index of $\xi \in \mathbb{A}_{E,f}$: the index of $\xi\hat{O}_E$ in $\hat{O}_E$ for

integral ξ, extended multiplicatively to the units and 0 on non-units; for $\xi \in E^\times$ it is $|N_{E/\mathbb{Q}}(\xi)|$. E is *stably unramified* if it contains a primitive root of unity of order 5040. A *shape* is a triple $\mathfrak{s} = (\varrho, \kappa, k_0)$; $\varrho(\mathfrak{s})$, $k(\mathfrak{s}) = \#\kappa$; a *level* is an element j of $\{0, \dots, \varrho(\mathfrak{s}) + 1\}$. For a matrix X over a ring with involution, X^* is the conjugate transpose; a matrix *has a left inverse* if its columns are linearly independent, and its *column span* is the space spanned by its columns. Index sets written $\mathcal{C}$, $\mathcal{C}'$ are finite index sets of columns of matrices; where the formal text lists such a set, its finiteness or a matrix among the arguments of a statement that does not use them, this is said in §6. As in Note F, and unlike in the handout's overview, c, c' are classes of the filling data and s, t elements of the finite group $\mathsf{G}(S)$; the complex variable and the unit class of the overview do not occur.

Setting 2.1 (filling data)**.** E is a CM field with its CM type, $\mathfrak{s}$ is a shape, and S is filling data over E of shape $\mathfrak{s}$, in the sense of the set-up of this unit, with its prime $N(S)$, the number $g(S)$, the finite group $\mathsf{G}(S)$, the classes $\mathrm{Cl}(S)$, the groups $G_S(E)$ and G_S^{lat}, the integral subgroup $K(S)$ with its reduction red_S and kernel $K_g(S)$, the positions $\mathrm{pos}_S(c, c'; \gamma)$ and the sets of terms $\mathrm{Tm}_S(c, s, c')$, as recalled in the setting "filling data" of Note F of this unit (*Translates of Poincaré series fill the rows*).

Recalled definitions. All the notions below belong to the set-up of the unit; they are recalled with every argument of their formal definitions. The index set $I(\mathfrak{s})$ of the whole space consists of $e_0, \dots, e_{\varrho(\mathfrak{s})-1}$, of κ, of z and of $e_0^*, \dots, e_{\varrho(\mathfrak{s})-1}^*$; $M(\mathfrak{s}) = \kappa \sqcup \{z\}$ indexes the *middle*. X is the span of the e_a; the frame is $\mathfrak{f}_a = e_a$ $(a < \varrho(\mathfrak{s}))$, $\mathfrak{f}_{\varrho(\mathfrak{s})} = z$. In Setting 2.1: $T = T_S^{\mathrm{rat}}(E)$ is the diagonal matrix on $M(\mathfrak{s})$ with entries 1 on κ and $-N(S)$ at z; J_S is its split Gram matrix on $I(\mathfrak{s})$, the Gram matrix of the hermitian form h; $T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})$ and its split Gram matrix J_f are the same in the lattice basis over the finite adeles.

(a) For $\gamma \in G_S(E)$: $Z_S(\gamma) = (h(\mathfrak{f}_a, \gamma\mathfrak{f}_{a'}))_{a,a'}$ is the frame Gram matrix, $D_l(Z)$ the leading minor of order l of a matrix Z, and the *term discriminant* is

$$\mathfrak{g}_S(\gamma) = |D_{\varrho+1}(Z_S(\gamma))|^2 - N(S)^2 |D_\varrho(Z_S(\gamma))|^2,$$

with $|\xi|^2 = \xi\bar{\xi}$; $\|\mathfrak{g}\|_S(\gamma) = \prod_\tau |\mathfrak{g}_S(\gamma)_\tau|$.

(b) $[\mathfrak{f} \mid \gamma\mathfrak{f}] = (\mathfrak{f} \,|\, \gamma\mathfrak{f})$ is the matrix of the frame and its image, $[\mathfrak{e} \mid \gamma\mathfrak{e}] = (e_a \,|\, \gamma e_a)_{a<\varrho(\mathfrak{s})}$ its part on X. The *link matrix* $\mathrm{L}(\gamma)$ sends a vector t to the pair of the middle parts of t and of $\gamma^{-1}t$, a vector indexed by $M(\mathfrak{s}) \sqcup M(\mathfrak{s})$; and $\mathrm{link}(\gamma) = \mathrm{L}(\gamma)(\ker([\mathfrak{e} \mid \gamma\mathfrak{e}]^* J_S))$, the *link*: the pairs of the classes of t and of $\gamma^{-1}t$ for t orthogonal to X and γX.

(c) $\mathrm{L}_z(T)$ is the matrix with two rows that takes from a pair of middle vectors the two products with the row of T at z; $Q_S^{\pm} = \mathrm{diag}(T, -T)$ is the *link form* and

$$Q_S^{\mathrm{link}} = \tfrac{1}{2}\,\mathrm{diag}(T, T) + N(S)^{-1}\,\mathrm{L}_z(T)^* \mathrm{L}_z(T)$$

the *link metric*, both on pairs of middle vectors. For γ, γ', the subspace $\mathrm{link}^\circ(\gamma, \gamma')$ of E^κ is the space of the κ-parts of the first components of the pairs in $\mathrm{link}(\gamma) \cap \mathrm{link}(\gamma') \cap \ker \mathrm{L}_z(T)$.

(d) For a matrix v over E on pairs of middle vectors with columns $\mathcal{C}$ and $e \in \mathrm{GL}_{\mathcal{C}}(\mathbb{A}_{E,f})$: $\mathrm{ld}_S(v, e) = |N_{E/\mathbb{Q}} \det(v^* Q_S^{\mathrm{link}} v)| \cdot [\det e]^2$.

(e) For a class c, $\mathrm{C}_S(c)$ is the matrix over $\mathbb{A}_{E,f}$ that takes rational coordinates on the whole space to coordinates in the basis of the lattice of c, and $\mathrm{C}^\circ_S(c)$ the matrix whose columns are the basis vectors of E^κ in the basis of the middle part of that lattice. For classes c, c', $\gamma \in G_S(E)$ and $k = \mathrm{pos}_S(c, c'; \gamma)$: $\mathrm{C}_S(c)\,[\widetilde{\mathfrak{f} \mid \gamma\mathfrak{f}}] = [\mathfrak{f} \mid k\mathfrak{f}]$.

(f) For a class c, $\gamma \in G_S(E)$ and a matrix m over $\mathbb{A}_{E,f}$ on pairs of middle vectors with columns $\mathcal{C}$: $m \in \mathrm{IL}(c; \gamma)$ (*m has integral lifts*) if there are a finite index set $\mathcal{C}'$, a matrix t over E with rows $I(\mathfrak{s})$ and columns $\mathcal{C}'$ and a matrix w over $\mathbb{A}_{E,f}$ with rows $\mathcal{C}'$ and columns $\mathcal{C}$ such that $[\mathfrak{e} \mid \gamma\mathfrak{e}]^* J_S\, t = 0$, the matrix $\mathrm{C}_S(c)\,\tilde{t}\,w$ is integral, and $\widetilde{\mathrm{L}(\gamma)t}\,w = m$.

(g) For $k \in G_S^{\mathrm{lat}}$ with frame Gram matrix $Z(k)$ for $T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})$ and a level j: $\mathrm{i}_{S,j}(k)$ is the index of the $\hat{O}_E$-span of the conjugated first $\min(j, \varrho(\mathfrak{s}))$ rows of $Z(k)$ in that of its conjugated first $\varrho(\mathfrak{s})$ rows, and $\mathfrak{d}_S(k)$ the index of the $\hat{O}_E$-span of the columns of $[\mathfrak{e} \mid k\mathfrak{e}]$ in the lattice of the integral vectors of their span; both are 0 if infinite.

(h) For a class c and a subspace V of E^κ: $\mathrm{disc}_{S,c}(V)$ is the discriminant of the lattice of the adelic points of V that are integral in the lattice of c; for $k \in G_S^{\mathrm{lat}}$ and a unit a of $\mathbb{A}_{E,f}$, $\mathrm{o}_{S,c}(k; a, V)$ is the index in the lattice of the values $(h(k\mathfrak{f}_l, y))_{l<\varrho(\mathfrak{s})}$, for y in that lattice of V, of its intersection with a times the lattice spanned by the conjugated first $\varrho(\mathfrak{s})$ rows of $Z(k)$ (0 if infinite). The *invariant of a pair* is

$$\begin{aligned}\mathrm{pi}_S(c, c'; \gamma, \gamma') = {} & \mathrm{disc}_{S,c}(\mathrm{link}^\circ(\gamma, \gamma')) \cdot \mathrm{o}_{S,c}(\mathrm{pos}_S(c, c'; \gamma); 1, \mathrm{link}^\circ(\gamma, \gamma')) \\ & \cdot \mathfrak{d}_S(\mathrm{pos}_S(c, c'; \gamma)).\end{aligned}$$

(i) For a level j, $\gamma \in G_S(E)$ and classes c, c', with $k = \mathrm{pos}_S(c, c'; \gamma)$, the *minor norm* and the *gauge* are

$$\mathrm{mn}_S(j; \gamma) = |N_{E/\mathbb{Q}}(D_j(Z_S(\gamma)))| \cdot N(S)^{-2(j-\varrho(\mathfrak{s}))_+ f(E)},$$

$$\mathrm{cg}_S(j; c, c'; \gamma) = \frac{\max(\|\mathbf{g}\|_S(\gamma),\ N(S)^{f(E)}\mathrm{mn}_S(j; \gamma))}{\mathrm{i}_{S,j}(k) \cdot \mathrm{i}_{S,j}(k^{-1})}.$$

(j) $\gamma \in \mathrm{Lv}_j(S)$ (γ *has level* j) if γ is in normal form of index j, $D_j(Z_S(\gamma)) \neq 0$, and $\varrho(\mathfrak{s}) < j$ holds exactly if $\mathbf{g}_S(\gamma) \neq 0$. Here γ is in *normal form of index* j if there is $v \in E$ with $v\bar{v} = 1$ such that for every frame index $a \geq j$ there are coefficient vectors x, y supported on the indices $\leq a$ with $x_a = v$, $y_a = 1$ and $\sum_{a'} x_{a'}\mathfrak{f}_{a'} = \gamma \sum_{a'} y_{a'}\mathfrak{f}_{a'}$.

(k) $s \in \mathsf{G}(S)$ *agrees*, in symbols $s \in \mathrm{Agr}(S)$, if for all $u, u' \in K(S)$ in the Bessel unipotent group with $\mathrm{red}_S(u)\, s = s\, \mathrm{red}_S(u')$ the unipotent characters of u and u' are equal. For a natural number x, s *fixes norm at least* x, in symbols $\mathrm{fix}(s) \geq x$, in the sense of the definition of fixing sets recalled in Note F: there is a finite set of triples of an index $i \in \{0, 1\}$, a chosen place above the i-th prime of S and a Boolean, the product of whose primes is at least x, such that for each of them s, or its inverse adjoint if the Boolean is true, fixes at that place a non-zero vector of the span of the frame.

The symbols of (a) to (k) are those of the notes on the set-up of this unit, which state the definitions; the predicates of (k) are written there with their symbols and here in words.

3 What is taken for granted

Input 1 (links, levels, class coordinates; set-up of this unit). In Setting 2.1, for $\gamma, \gamma' \in G_S(E)$:

(a) $\dim_E \mathrm{link}(\gamma) = k(\mathfrak{s}) + 1$, and $\mathrm{link}(\gamma)$ is Lagrangian for the link form: a pair p lies in $\mathrm{link}(\gamma)$ exactly if $q^* Q_S^{\pm} p = 0$ for all $q \in \mathrm{link}(\gamma)$. In particular $v^* Q_S^{\pm} u = 0$ for matrices u, v with columns in $\mathrm{link}(\gamma)$.

(b) If the columns of t are orthogonal to $X + \gamma X$ and those of t' to $X + \gamma' X$, then for $a, a' \in E$: $(\mathrm{L}(\gamma)t)^* \,\mathrm{diag}(aT, -a'T)(\mathrm{L}(\gamma')t') = a\, t^* J_S t' - a'\, t^* J_S (\gamma\gamma'^{-1}) t'$.

(c) The link metric is positive definite at every infinite place, and $\det(v^* Q_S^{\mathrm{link}} v) \neq 0$ for every matrix v with a left inverse.

(d) For matrices t, t' over E with rows $I(\mathfrak{s})$: $(\mathrm{C}_S(c)\tilde{t})^* J_f (\mathrm{C}_S(c)\tilde{t}') = \widetilde{t^* J_S t'}$; J_f is unimodular; and the frame Gram matrix of $\mathrm{pos}_S(c, c'; \gamma)$ is the image of $Z_S(\gamma)$.

(e) If $\gamma \in \mathrm{Lv}_j(S)$, then $\gamma^{-1} \in \mathrm{Lv}_j(S)$ and $\mathrm{mn}_S(j; \gamma) > 0$. If γ is in normal form of index j, then for every vector y of frame coordinates there are x, y' with $y'_a = y_a$ for $a \geq j$ and $\sum_a x_a \mathfrak{f}_a = \gamma \sum_a y'_a \mathfrak{f}_a$; in such a relation the top coordinates satisfy $\bar{x}_\varrho x_\varrho = \bar{y}'_\varrho y'_\varrho$. If $\gamma \in \mathrm{Lv}_j(S)$ and $b \geq j$ is a frame index, the combination of the vectors $\gamma \mathfrak{f}_a$ with the coefficients of column b of the inverse of the matrix $\mathrm{pl}_j(Z_S(\gamma))$, whose rows $a < j$ are those of $Z_S(\gamma)$ and whose other rows are those of the identity, lies in the span of the frame.

(f) If $Z_S(\gamma)\, y = D\, e_\varrho$ for a coefficient vector y and $D \in E$, and $t = \sum_a y_a \gamma \mathfrak{f}_a$, then the coordinates of t at the e_a^* vanish, $-N(S)\, t_z = D$, and $N(S) \sum_{i \in \kappa} |t_i|^2 = |D|^2 - N(S)^2 |y_\varrho|^2$.

(g) If $\gamma \in \mathrm{Tm}_S(c, s, c')$ and $\gamma' \in \mathrm{Tm}_S(c', s', c'')$, then $\gamma\gamma' \in \mathrm{Tm}_S(c, ss', c'')$; the inverse of a term over (c, s, c') is a term over (c', s^{-1}, c); and the position of a term over $(c, 1, c)$ lies in $K_g(S)$, so that it is congruent to 1 modulo $g(S)$.

(h) If the columns of n are orthogonal to $X + kX$ for $k \in G(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and $\mathrm{L}_z(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))\mathrm{L}(k)n = 0$, then $\mathrm{fm}(k)^*\, T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})\, n_M = -Z_X(k)^*\, n_X$, where n_X is the part of n on the e_a, n_M its middle part, $\mathrm{fm}(k)$ the matrix of the middle parts of the $k\mathfrak{f}_l$, $l < \varrho(\mathfrak{s})$, and $Z_X(k)$ the matrix of the first $\varrho(\mathfrak{s})$ rows of $Z(k)$.

Input 2 (Liouville's inequality for Gram determinants; set-up of this unit). Let E be stably unramified, Q a square matrix over E that is positive definite at every infinite place, a, a' matrices over E with the rows of Q and columns indexed by a finite set $\mathcal{C}$ with $\det(a^* Q a') \neq 0$, $v, v' \in \mathrm{GL}_{\mathcal{C}}(\mathbb{A}_{E,f})$, and $x_0 \geq 0$ a real number such that $x_0 \leq [\delta]$ whenever $\delta = \det(v^* \widetilde{a^* Q a'}\, v')$ is a unit of $\mathbb{A}_{E,f}$. Then $x_0^2 \leq [\det v]^2\, |N_{E/\mathbb{Q}} \det(a^* Q a)| \cdot |N_{E/\mathbb{Q}} \det(a'^* Q a')|\, [\det v']^2$.

Input 3 (lattices; set-up of this unit and background library). Let E be stably unramified.

(a) *(Primitive completion.)* If a matrix over $\mathbb{A}_{E,f}$ with columns $\mathcal{C} \sqcup \mathcal{C}'$ has a left inverse, it becomes primitive (its columns extend to a basis of the lattice of integral vectors) after multiplication on the right by a block matrix with diagonal blocks $a \in \mathrm{GL}_{\mathcal{C}}(\mathbb{A}_{E,f})$, $e \in \mathrm{GL}_{\mathcal{C}'}(\mathbb{A}_{E,f})$, an upper right block z and lower left block 0. A square primitive matrix is integral with integral inverse, so its determinant has generalised index 1.

(b) *(Jacobi's identity for discriminants of complements; reference to be confirmed.)* Let J be a unimodular hermitian matrix over $\mathbb{A}_{E,f}$, F an integral matrix, n a primitive matrix with $F^* J n = 0$, of complementary sizes, p a matrix of bordering columns and c_0 a unit. Then the solutions u' of $n^* J u' = 0$ are the combinations of the columns of F, and

$$[\det(n^*(J + c_0^{-1} J p p^* J) n)] \cdot \mathfrak{i}(F)^2 \cdot [c_0]^{d_p} = [\det M],$$

where M is the Gram matrix of $(F \,|\, p)$ for J with c_0 added on the diagonal block of p, d_p is the number of columns of p, and $\mathfrak{i}(F)$ the index of the lattice of integral vectors in the lattice of the y with Fy integral.

(c) *(Extension of a basis modulo a kernel.)* Let A and x be matrices over E with $\det(Ax) \neq 0$, and L a subspace containing the columns of x. Then there is a matrix y with $\dim(L \cap \ker A)$ columns such that $(x \,|\, y)$ has a left inverse and its columns span L, the columns of y lie in L, $Ay = 0$, and yt lies in the column span of x only for $t = 0$.

(d) *(Discriminant of a sublattice.)* Let c be a class, V a subspace of E^κ of dimension d, p a matrix over E with d columns in V, $a \in \mathrm{GL}_d(\mathbb{A}_{E,f})$ with $D = [\det(p^* p)]\,[\det a]^2 \neq 0$, and k in G_S^{lat}. If $\mathrm{C}_S^\circ(c)\,\tilde{p}\,a$ is integral and its values $(h(k\mathfrak{f}_l, \cdot))_l$ lie in the lattice spanned by the conjugated first $\varrho(\mathfrak{s})$ rows of $Z(k)$, then $(\mathrm{disc}_{S,c}(V) \cdot \mathrm{o}_{S,c}(k; 1, V))^2 \leq D$, $\mathrm{disc}_{S,c}(V) > 0$ and $\mathrm{o}_{S,c}(k; 1, V) \geq 1$.

Input 4 (agreeing characters force a large index; set-up of this unit). In Setting 2.1, let E be stably unramified, $k \in K(S)$ with $\mathrm{red}_S(k)$ agreeing, x a natural number such that $\mathrm{red}_S(k)$ fixes norm at least x, and n an integral matrix with rows $I(\mathfrak{s})$ and two columns whose *pairings* with the e_a and the $k e_a$ vanish, that is $[\mathfrak{e} \mid k\mathfrak{e}]^* J_f\, n = 0$; here the pairing of a column v of n with a vector w is $w^* J_f v = h(w, v)$. If the determinant δ of the 2×2 matrix of the pairings of the columns of n with z and kz is a unit of $\mathbb{A}_{E,f}$, then $x \leq [\delta]$. (The formal statement is about an integral matrix t and the plain products $[\mathfrak{f} \mid k\mathfrak{f}]^* t$; it is used for $t = J_f n$, which is integral because n and J_f are.)

4 Proofs

Throughout, in Setting 2.1, $N = N(S)$, $\varrho = \varrho(\mathfrak{s})$, $T = T_S^{\mathrm{rat}}(E)$, and $[N] = N^{2f(E)}$ is the generalised index of the integer N, the degree of E being $2f(E)$.

The bordered determinant.

Lemma 4.1 (a bordered Gram determinant)**.** *In Setting 2.1, let j be a level and $\gamma \in G_S(E)$ with $\gamma \in \mathrm{Lv}_j(S)$. Let P be the matrix over E with rows $I(\mathfrak{s})$ whose columns are: the vectors e_a for $a < \varrho(\mathfrak{s})$; the vectors γe_a for $a < \varrho(\mathfrak{s})$ with $a < j$; the basis vectors e_a^* for $a < \varrho(\mathfrak{s})$ with $a \geq j$; and z and γz. Let M be the sum of $P^* J_S P$ and of the diagonal matrix with entry $N(S)$ at the columns e_a^*, z, γz and 0 at the others. Then*

$$[\det \tilde{M}] = \left(N(S)^{2f(E)} \cdot \mathrm{mn}_S(j;\gamma)\right)^2.$$

Proof. Let $Z' = Z_S(\gamma^{-1})$, the conjugate transpose of $Z_S(\gamma)$, and let A be the square matrix of size $\varrho + 1$ whose rows $a < j$, $a < \varrho$, are those of Z', whose rows $j \leq a < \varrho$ are those of the identity, and whose top row is that of Z'.

Order the columns of P as the frame $\mathfrak{f}_0, \dots, \mathfrak{f}_\varrho$ (the e_a, $a < \varrho$, and z), followed by the $\varrho + 1$ columns γe_b ($b < \min(j, \varrho)$), e_b^* ($j \leq b < \varrho$) and γz, which we index by $b \leq \varrho$, the column γz having the index ϱ. On the frame, M is the matrix $(h(\mathfrak{f}_a, \mathfrak{f}_{a'}))_{a,a'} + \mathrm{diag}(0, \dots, 0, N)$, which is zero: the e_a are isotropic and orthogonal to z, and $h(z,z) = -N$. The block of the frame against the other columns has the entries

$$h(\mathfrak{f}_a, \gamma e_b) = Z_S(\gamma)_{ab}, \qquad h(\mathfrak{f}_a, e_b^*) = \delta_{ab}, \qquad h(\mathfrak{f}_a, \gamma z) = Z_S(\gamma)_{a\varrho};$$

its columns $b < \min(j, \varrho)$ and $b = \varrho$ are those of $Z_S(\gamma) = Z'^*$ and its columns $j \leq b < \varrho$ are those of the identity, so it is A^*. As M is hermitian,

$$M = \begin{pmatrix} 0 & A^* \\ A & * \end{pmatrix}, \qquad \det M = \pm \det A \cdot \overline{\det A},$$

and as $\det M \in E$, $[\det \tilde{M}] = |N_{E/\mathbb{Q}}(\det A)|^2$. It remains to show $|N_{E/\mathbb{Q}}(\det A)| = N^{2f(E)} \mathrm{mn}_S(j;\gamma)$.

If $j = \varrho + 1$, then $A = Z'$, $|N_{E/\mathbb{Q}} \det Z'| = |N_{E/\mathbb{Q}} D_{\varrho+1}(Z_S(\gamma))|$, and the claim is the definition of $\mathrm{mn}_S(\varrho + 1; \gamma)$, in which $(j - \varrho)_+ = 1$.

Let $j \leq \varrho$. The element γ^{-1} has level j (Input 1(e)), so for the frame index $\varrho \geq j$ the combination of the $\gamma^{-1}\mathfrak{f}_a$ with the coefficients y of the top column of $\mathrm{pl}_j(Z')^{-1}$ lies in the span of the frame: $\sum_a y_a \gamma^{-1} \mathfrak{f}_a = \sum_a x_a \mathfrak{f}_a$. The matrix A differs from $\mathrm{pl}_j(Z')$ only in the top row, so by Cramer's rule $\det A = \det \mathrm{pl}_j(Z') \cdot (Z'y)_\varrho$, and $\det \mathrm{pl}_j(Z') = D_j(Z') \neq 0$. Now $(Z'y)_\varrho = h(z, \sum_a y_a \gamma^{-1} \mathfrak{f}_a) = h(z, \sum_a x_a \mathfrak{f}_a) = -N x_\varrho$, and $\bar{x}_\varrho x_\varrho = \bar{y}_\varrho y_\varrho = 1$, because the top diagonal entry of $\mathrm{pl}_j(Z') \, \mathrm{pl}_j(Z')^{-1}$ is 1 and the top row of $\mathrm{pl}_j(Z')$ is that of the identity. So $\det A = -N x_\varrho \, D_j(Z')$ with x_ϱ of norm one at every place, and

$$|N_{E/\mathbb{Q}}(\det A)| = N^{2f(E)} \, |N_{E/\mathbb{Q}} D_j(Z_S(\gamma))| = N^{2f(E)} \mathrm{mn}_S(j;\gamma),$$

the leading minors of Z' being the conjugates of those of $Z_S(\gamma)$. □

LEAN `Filling.HasLevel.abs_norm_bordered_det`

Integral lifts of a basis of the link.

Proposition 4.2 (lifts with small discriminant)**.** *In Setting 2.1, suppose that E is stably unramified. Let c, c' be classes of S, $t \in \mathsf{G}(S)$, j a level, $\gamma \in \mathrm{Tm}_S(c,t,c')$ with $\gamma \in \mathrm{Lv}_j(S)$, $\mathcal{C}$ a finite index set and v a matrix over E with rows $M(\mathfrak{s}) \sqcup M(\mathfrak{s})$ and columns $\mathcal{C}$ that has a left inverse and whose column span is $\mathrm{link}(\gamma)$. Put $k = \mathrm{pos}_S(c,c';\gamma)$ and $w_0 = \mathrm{i}_{S,j}(k) \cdot \mathrm{i}_{S,j}(k^{-1}) \cdot \mathfrak{d}_S(k)$. Then there is $e \in \mathrm{GL}_{\mathcal{C}}(\mathbb{A}_{E,f})$ such that*

$$\tilde{v}\, e \in \mathrm{IL}(c;\gamma), \qquad \mathrm{ld}_S(v,e) \cdot w_0^2 \le \mathrm{mn}_S(j;\gamma)^2, \qquad w_0 \neq 0.$$

Proof. Let B be the set of the $a < \varrho$ with $a \ge j$; it is empty if $j \ge \varrho$.

Step 1: a rational lift. There is a matrix u over E with rows $I(\mathfrak{s})$ and columns $B \sqcup \mathcal{C}$ such that the columns of u are orthogonal to $X + \gamma X$; $\mathrm{L}(\gamma)u = (0 \,|\, v)$; and the e_a-coordinates of the columns of u, for $a \in B$, form the matrix $(1 \,|\, 0)$. Indeed, a column v_b of v lies in the link, so $v_b = \mathrm{L}(\gamma)t_b$ with t_b orthogonal to $X + \gamma X$. By the normal form of γ^{-1} (Input 1(e)), for every prescription of coordinates at the indices $a \in B$ there is a vector $w' = \sum_a y'_a e_a$ with these coordinates, with $y'_\varrho = 0$, such that $\gamma^{-1}w' = \sum_a x_a \mathfrak{f}_a$ with $x_\varrho = 0$. Then w' lies in $X \cap \gamma X$; it is orthogonal to $X + \gamma X$, both spaces being isotropic, and $\mathrm{L}(\gamma)w' = 0$, the middle parts of w' and of $\gamma^{-1}w'$ being zero. Adding such vectors to the t_b, and taking them alone for the columns of B, gives u.

Step 2: completion. The matrix $\mathrm{C}_S(c)\tilde{u}$ has a left inverse. By Input 3(a) there are $a \in \mathrm{GL}_B(\mathbb{A}_{E,f})$, $e \in \mathrm{GL}_{\mathcal{C}}(\mathbb{A}_{E,f})$ and z_1 such that $n = \mathrm{C}_S(c)\,\tilde{u}\,\left(\begin{smallmatrix} a & z_1 \\ 0 & e \end{smallmatrix}\right)$ is primitive. The columns of n indexed by $\mathcal{C}$ are $\mathrm{C}_S(c)\tilde{u}\binom{z_1}{e}$; they are integral, and $\widetilde{\mathrm{L}(\gamma)u}\binom{z_1}{e} = \tilde{v}\, e$. With Step 1 this shows $\tilde{v}\, e \in \mathrm{IL}(c;\gamma)$.

Step 3: Jacobi's identity. Let F and p' be the images under $\mathrm{C}_S(c)$ of the first columns (e_a for $a < \varrho$; γe_a for $a < j$, $a < \varrho$) and of the last columns (e_a^* for $a \in B$; z; γz) of the matrix P of Lemma 4.1; by the last sentence of §2(e), F consists of the vectors e_a and ke_a. The matrix F is integral because $k \in K(S)$; $F^* J_f n = 0$ by Step 1 and Input 1(d); and the sizes are complementary because $\#\mathcal{C} = k(\mathfrak{s}) + 1$ (Input 1(a)). Jacobi's identity (Input 3(b)), for $J = J_f$, F, n, p' and $c_0 = N$, gives

$$\left[\det(n^*(J_f + N^{-1}J_f p' p'^* J_f)n)\right] \cdot \mathfrak{i}(F)^2 \cdot [N]^{\#B+2} = [\det \tilde{M}] = \left(N^{2f(E)}\mathrm{mn}_S(j;\gamma)\right)^2,$$

the Gram matrix in the coordinates of the lattice being the rational one (Input 1(d)) and the last equality being Lemma 4.1. On the left, with Q the matrix of the products of the columns of u with e_a^* ($a \in B$), z and γz,

$$n^*(J_f + N^{-1}J_f p' p'^* J_f)n = \left(\begin{smallmatrix} a & z_1 \\ 0 & e \end{smallmatrix}\right)^* \left(u^* J_S u + \widetilde{N^{-1}Q^*Q}\right) \left(\begin{smallmatrix} a & z_1 \\ 0 & e \end{smallmatrix}\right),$$

$$u^* J_S u + N^{-1}Q^*Q = \begin{pmatrix} N^{-1} \cdot 1_B & 0 \\ 0 & v^* Q_S^{\mathrm{link}} v \end{pmatrix}.$$

The second identity follows from Step 1. A column of u indexed by B lies in $X \cap \gamma X$: its products with z, γz and with the other columns vanish, and its products with the e_a^*, $a \in B$, are its e_a-coordinates; this gives the block $N^{-1} \cdot 1_B$ and the zero blocks. For the columns indexed by $\mathcal{C}$, the products with the e_a^*, $a \in B$, vanish, the products with z and γz are the values of $\mathrm{L}_z(T)$ on the link images, which gives the term

$N^{-1}\mathrm{L}_z(T)^*\mathrm{L}_z(T)$ of the link metric, and Input 1(b), with $\gamma' = \gamma$ and the coefficients $\frac{1}{2}$, $-\frac{1}{2}$, gives $u^* J_S u = v^* \frac{1}{2}\operatorname{diag}(T,T)\, v$ on them. Taking generalised indices,

$$[\det a]^2\,[\det e]^2 \cdot [N]^{-\#B} \cdot |N_{E/\mathbb{Q}} \det(v^* Q_S^{\mathrm{link}} v)| \cdot \mathfrak{i}(F)^2 \cdot [N]^{\#B+2} = [N]^2\, \mathrm{mn}_S(j;\gamma)^2,$$

that is

$$\mathrm{ld}_S(v,e) \cdot [\det a]^2 \cdot \mathfrak{i}(F)^2 = \mathrm{mn}_S(j;\gamma)^2. \tag{1}$$

Step 4: the indices. The formal text shows two divisibilities. First, the matrix a is integral, the index of its column lattice in the integral vectors is $[\det a] \neq 0$, and by the relation of Input 1(h), applied to the columns of n indexed by B, and the description of the frame Gram matrix of k (Input 1(d)), the lattice of the conjugated first ϱ rows of $Z(k)$ is generated by that of its first $\min(j,\varrho)$ rows and the image of the column lattice of a; so $\mathrm{i}_{S,j}(k)$ divides $[\det a]$. Second, $\mathrm{i}_{S,j}(k^{-1})$ divides the index of the column lattice of $[\mathfrak{e} \mid k\mathfrak{e}]$ in that of F, $\mathfrak{d}_S(k)$ is the index of the column lattice of $[\mathfrak{e} \mid k\mathfrak{e}]$ in the lattice of the integral vectors of its span, and by the first assertion of Jacobi's identity that lattice lies in the lattice of the y with Fy integral; as indices multiply, $\mathrm{i}_{S,j}(k^{-1}) \cdot \mathfrak{d}_S(k)$ divides $\mathfrak{i}(F)$, which is non-zero by (1) and $\mathrm{mn}_S(j;\gamma) > 0$. Hence $w_0 \neq 0$, $w_0 \leq [\det a]\,\mathfrak{i}(F)$, and (1) gives $\mathrm{ld}_S(v,e)\, w_0^2 \leq \mathrm{mn}_S(j;\gamma)^2$. □

LEAN `Filling.exists_lifts_linkDiscSq_le`

Corollary 4.3 (positivity)**.** *In Setting 2.1, suppose that E is stably unramified. Let c, c' be classes of S, $s \in \mathsf{G}(S)$, j a level and $\gamma \in \mathrm{Tm}_S(c,s,c')$ with $\gamma \in \mathrm{Lv}_j(S)$, and $k = \mathrm{pos}_S(c,c';\gamma)$. Then $1 \leq \mathrm{i}_{S,j}(k)$, $1 \leq \mathfrak{d}_S(k)$ and $0 < \mathrm{cg}_S(j;c,c';\gamma)$.*

Proof. Apply Proposition 4.2 to a basis of the link: $w_0 \neq 0$, so its three factors, which are natural numbers, are at least 1; and the numerator of the gauge is at least $N^{f(E)}\mathrm{mn}_S(j;\gamma) > 0$ (Input 1(e)). □

LEAN `Filling.one_le_xRowsIndex_and_saturationIndex`

Lemma 4.4 (an integral matrix from lifts)**.** *In Setting 2.1, let c be a class of S, $\gamma \in G_S(E)$, $\mathcal{C}$ an index set, m a matrix over $\mathbb{A}_{E,f}$ with rows $M(\mathfrak{s}) \sqcup M(\mathfrak{s})$ and columns $\mathcal{C}$, and c' a class of S. Suppose that $m \in \mathrm{IL}(c;\gamma)$. Then, with $k = \mathrm{pos}_S(c,c';\gamma)$, there is an integral matrix n with rows $I(\mathfrak{s})$ and columns $\mathcal{C}$ such that*

$$\mathrm{L}_z(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))\,\mathrm{L}(k)\,n = \widetilde{\mathrm{L}_z(T)}\,m, \qquad [\mathfrak{e} \mid k\mathfrak{e}]^* J_f n = 0,$$

and such that, for every matrix p with rows κ: if the first half of m is p on the rows κ and 0 on the row z, then the middle rows of n are $\mathrm{C}_S^\circ(c)\,p$.

Proof. Let $(\mathcal{C}', t, w)$ be as in the definition of integral lifts and put $n = \mathrm{C}_S(c)\tilde{t}w$. It is integral. As $\mathrm{C}_S(c)[\mathfrak{f} \mid \widetilde{\gamma\mathfrak{f}}] = [\mathfrak{f} \mid k\mathfrak{f}]$, Input 1(d) turns the pairings of n with the columns of $[\mathfrak{f} \mid k\mathfrak{f}]$ into those of $\tilde{t}w$ with the columns of $[\mathfrak{f} \mid \gamma\mathfrak{f}]$: those with the e_a, γe_a vanish, and those with z, γz, which are the values of $\mathrm{L}_z(\cdot)$ on the link images, are $\widetilde{\mathrm{L}_z(T)}\,\widetilde{\mathrm{L}(\gamma)}t\,w = \widetilde{\mathrm{L}_z(T)}\,m$. The last assertion is read off from the block form of $\mathrm{C}_S(c)$ on the middle coordinates. □

LEAN `Filling.HasIntegralLifts.exists_isIntMatrix`

Lemma 4.5 (orthogonal splitting of lifts)**.** *In Setting 2.1, suppose that E is stably unramified. Let c be a class of S, $\gamma \in G_S(E)$, $\mathcal{C}$ a finite index set, m a matrix over E with rows $M(\mathfrak{s}) \sqcup M(\mathfrak{s})$ and columns $\mathcal{C}$, d a natural number, y a matrix over E with the same rows and d columns, and f an invertible matrix over $\mathbb{A}_{E,f}$ with rows and*

columns indexed by $\mathcal{C}$ and the d columns of y. Suppose that $m^{*}Q_S^{\mathrm{link}}\,y = 0$ and that $\widetilde{(m \mid y)}f \in \mathrm{IL}(c;\gamma)$. Then there are $a \in \mathrm{GL}_{\mathcal{C}}(\mathbb{A}_{E,f})$, $v \in \mathrm{GL}_d(\mathbb{A}_{E,f})$ and a matrix z_1 over $\mathbb{A}_{E,f}$ with rows $\mathcal{C}$ and d columns such that

$$\tilde{m}a \in \mathrm{IL}(c;\gamma), \qquad \tilde{m}z_1 + \tilde{y}v \in \mathrm{IL}(c;\gamma), \qquad \mathrm{ld}_S(m,a)\cdot \mathrm{ld}_S(y,v) = \mathrm{ld}_S((m \mid y), f).$$

Proof. By Input 3(a), applied to f^{-1}, there are a, v, z_1 such that $f^{-1}\left(\begin{smallmatrix} a & z_1 \\ 0 & v \end{smallmatrix}\right)$ is primitive, in particular integral with $[\det a]\,[\det v] = [\det f]$. Let $(\mathcal{C}', t, w)$ be lift data for $\widetilde{(m \mid y)}f$. Then $(\tilde{m}a \mid \tilde{m}z_1 + \tilde{y}v) = \widetilde{\mathrm{L}(\gamma)t}\cdot w\, f^{-1}\left(\begin{smallmatrix} a & z_1 \\ 0 & v \end{smallmatrix}\right)$, and $\mathrm{C}_S(c)\tilde{t}\cdot w\, f^{-1}\left(\begin{smallmatrix} a & z_1 \\ 0 & v \end{smallmatrix}\right)$ is integral; taking the two blocks of columns gives the two lifts. Since $m^{*}Q_S^{\mathrm{link}}y = 0$, the Gram matrix of $(m \mid y)$ for the link metric is block diagonal, so its determinant is the product of those of m and of y; with $[\det f]^2 = [\det a]^2[\det v]^2$ this is the identity of the discriminants. □

LEAN `Filling.HasIntegralLifts.exists_orthogonal_split`

The vector that carries the term discriminant.

Lemma 4.6. *In Setting 2.1, let j be a level and $\gamma \in G_S(E)$ with $\gamma \in \mathrm{Lv}_j(S)$. Then there are $a \in E^{\kappa}$ and $y \in E$ such that the pair $(a - z,\ yz)$ of middle vectors lies in* $\mathrm{link}(\gamma)$*, and*

$$\mathrm{g}_S(\gamma) = D_j(Z_S(\gamma))\cdot \overline{D_j(Z_S(\gamma))}\cdot(1 - \bar{y}y).$$

Proof. It suffices to find a coefficient vector x such that $t = \sum_b x_b\gamma\mathfrak{f}_b$ has middle part $a - z$ and such that $\gamma^{-1}t = \sum_b x_b\mathfrak{f}_b$ has middle part yz, that is $y = x_{\varrho}$, with t orthogonal to X and γX: then the pair is the link image of t.

If $j = \varrho + 1$, then $D = \det Z_S(\gamma) = D_j(Z_S(\gamma)) \neq 0$; let x' be the solution of $Z_S(\gamma)x' = D\,e_{\varrho}$ and $x = (N/D)\,x'$, so that $Z_S(\gamma)x = N e_{\varrho}$. By Input 1(f) the vector $t = \sum_b x_b\gamma\mathfrak{f}_b$ has no coordinates at the e_a^{*} and has $t_z = -1$; so its middle part is $a - z$ with $a \in E^{\kappa}$, and it is orthogonal to X. It is orthogonal to γX because $h(\gamma e_a, t) = h(e_a, \sum_b x_b\mathfrak{f}_b) = 0$. By Cramer's rule $x'_{\varrho} = D_{\varrho}(Z_S(\gamma))$, the cofactor of the top entry; so $y = x_{\varrho} = N D_{\varrho}(Z_S(\gamma))/D$, and

$$\mathrm{g}_S(\gamma) = D\bar{D} - N^2|D_{\varrho}(Z_S(\gamma))|^2 = D\bar{D}(1 - \bar{y}y).$$

If $j \le \varrho$, the normal form of γ^{-1} for the prescription -1 at the top (Input 1(e)) gives x, y' with $y'_{\varrho} = -1$ and $\sum_b x_b\mathfrak{f}_b = \gamma^{-1}\sum_b y'_b\mathfrak{f}_b$; take $t = \sum_b y'_b\mathfrak{f}_b$, whose middle part is $-z$ (so $a = 0$), and $y = x_{\varrho}$, for which $\bar{y}y = \bar{y}'_{\varrho}y'_{\varrho} = 1$. Both t and $\gamma^{-1}t$ lie in the span of the frame, so t is orthogonal to X and to γX. As $j \le \varrho$, $\mathrm{g}_S(\gamma) = 0$ by the definition of the level, and $1 - \bar{y}y = 0$. □

LEAN `Filling.HasLevel.exists_mem_link_termDisc_eq`

Comparison of the minor with a partial discriminant.

Proposition 4.7. *In Setting 2.1, suppose that E is stably unramified. Let c, c' be classes of S, $s \in \mathsf{G}(S)$ an element that agrees, x a natural number such that s fixes norm at least x, j a level and $\gamma \in \mathrm{Tm}_S(c, s, c')$ with $\gamma \in \mathrm{Lv}_j(S)$. Let r and i be natural numbers, w a matrix over $\mathbb{A}_{E,f}$ with rows $M(\mathfrak{s}) \sqcup M(\mathfrak{s})$ and r columns, y a matrix over E with the same rows and r columns, and $v \in \mathrm{GL}_r(\mathbb{A}_{E,f})$. Suppose that*

(a) *if $i = 0$, then* $\dim(\mathrm{link}(\gamma) \cap \ker \mathrm{L}_z(T)) + r = \dim \mathrm{link}(\gamma)$*;*

(b) *the columns of y lie in* $\mathrm{link}(\gamma)$*, and* $\mathrm{L}_z(T)\,y$ *has a left inverse;*
(c) $w \in \mathrm{IL}(c;\gamma)$*, and* $\widetilde{\mathrm{L}_z(T)}\,w = \widetilde{\mathrm{L}_z(T)}\,y\,v$.

Then $r \le 1 + (j - \varrho(\mathfrak{s}))_+$ *and, with* $x' = x$ *if* $\varrho(\mathfrak{s}) < j$ *and* $i = 0$*, and* $x' = 1$ *otherwise,*

$$x'^2 \cdot \mathrm{mn}_S(j;\gamma)^2 \;\le\; \mathrm{ld}_S(y,v) \cdot \max\big(\|\mathfrak{g}\|_S(\gamma),\; N(S)^{f(E)}\mathrm{mn}_S(j;\gamma)\big)^2.$$

Proof. Let $k = \mathrm{pos}_S(c,c';\gamma) \in K(S)$ and let n be the integral matrix of Lemma 4.4 for w. By Lemma 4.6 for γ and for γ^{-1} there are pairs $\varepsilon_1 = (a - z,\; uz)$ in $\mathrm{link}(\gamma)$ with $\mathfrak{g}_S(\gamma) = D_j\bar{D}_j(1-\bar{u}u)$, $D_j = D_j(Z_S(\gamma))$, and $(a' - z,\; u'z)$ in $\mathrm{link}(\gamma^{-1})$; exchanging the two components of the latter gives a second pair $\varepsilon_2 = (u'z,\; a' - z)$ in $\mathrm{link}(\gamma)$. Let ε be the matrix with the columns ε_1, ε_2.

Two identities. For every matrix w' with columns in $\mathrm{link}(\gamma)$,

$$\varepsilon^*\, Q_S^{\mathrm{link}}\, w' = \mathrm{L}_z(T)\, w', \qquad \mathrm{L}_z(T)\,\varepsilon = N\begin{pmatrix} 1 & -\bar{u} \\ -u & 1 \end{pmatrix}. \tag{2}$$

Indeed the value of $\mathrm{L}_z(T)$ on a pair with coordinates s_1, s_2 at z is $(-Ns_1, -Ns_2)$, which gives $\mathrm{L}_z(T)\varepsilon$ with the entry $-Nu'$ in the upper right corner; and $\varepsilon_1^* Q_S^{\pm}\varepsilon_2 = 0$ (Input 1(a)) reads $Nu' - N\bar{u} = 0$, so $u' = \bar{u}$. For the first identity write $Q_S^{\mathrm{link}} = \frac{1}{2}Q_S^{\pm} + \mathrm{diag}(0,T) + N^{-1}\mathrm{L}_z(T)^*\mathrm{L}_z(T)$; the link form vanishes on the link, and the two other terms, computed from the coordinates of ε_1, ε_2 and using once more that $\varepsilon_2^* Q_S^{\pm} w' = 0$, add up to $\mathrm{L}_z(T)w'$.

A minor. As $\mathrm{L}_z(T)y$ has two rows and a left inverse, $r \le 2$, and there is an injective map ς_0 from the r columns to the two rows such that the corresponding minor of $\mathrm{L}_z(T)y$ is non-zero. Let $\varepsilon_{\varsigma_0}$ be the matrix of the columns of ε selected by ς_0; by (2) the matrix $\varepsilon_{\varsigma_0}^* Q_S^{\mathrm{link}} y$ is that minor's matrix, so its determinant is non-zero.

Liouville's inequality (Input 2, with $Q = Q_S^{\mathrm{link}}$, which is positive definite at the infinite places, $a = \varepsilon_{\varsigma_0}$, $a' = y$, the identity and v) gives

$$x'^2 \;\le\; |N_{E/\mathbb{Q}} \det(\varepsilon_{\varsigma_0}^* Q_S^{\mathrm{link}} \varepsilon_{\varsigma_0})| \cdot \mathrm{ld}_S(y,v), \tag{3}$$

provided $x' \le [\delta]$ whenever $\delta = \det\big((\widetilde{\mathrm{L}_z(T)}\,y\,v)_{\varsigma_0}\big) = \det\big((\widetilde{\mathrm{L}_z(T)}w)_{\varsigma_0}\big)$ is a unit. By Lemma 4.4, $\widetilde{\mathrm{L}_z(T)}w$ is the matrix of the pairings of the columns of the integral matrix n with z and kz, and the pairings of n with the e_a, ke_a vanish; these are the pairings $w^* J_f v$ of Input 4. If $\varrho < j$ and $i = 0$, then $\mathfrak{g}_S(\gamma) \neq 0$, so $1 - \bar{u}u \neq 0$ and $\mathrm{L}_z(T)\varepsilon$ is invertible; hence $\dim \mathrm{link}(\gamma) = 2 + \dim(\mathrm{link}(\gamma) \cap \ker \mathrm{L}_z(T))$, hypothesis (a) gives $r = 2$, the minor is the full determinant, and Input 4 gives $x \le [\delta]$; otherwise $x' = 1 \le [\delta]$ because δ is a unit that is the determinant of an integral matrix.

The determinant of the selected block. By (2), $\varepsilon^* Q_S^{\mathrm{link}} \varepsilon = \mathrm{L}_z(T)\varepsilon$. If $r = 0$, the determinant in (3) is 1. If $r = 1$, it is a diagonal entry, equal to N, of absolute norm $N^{2f(E)}$. If $r = 2$, it is $N^2(1 - \bar{u}u)$, and it is non-zero: $\mathrm{L}_z(T)y = \varepsilon^* Q_S^{\mathrm{link}} y$ is invertible, so ε has rank 2 and the link metric is positive definite. Hence $\mathfrak{g}_S(\gamma) = D_j\bar{D}_j(1-\bar{u}u) \neq 0$ and $j = \varrho + 1$ by the definition of the level; so $r \le 1 + (j - \varrho)_+$ in all cases. Moreover, as $|N_{E/\mathbb{Q}}(\xi)| = \prod_\tau |\xi_\tau|^2$ and $\mathrm{mn}_S(\varrho+1;\gamma) = |N_{E/\mathbb{Q}}(D_j)|\, N^{-2f(E)}$, $|N_{E/\mathbb{Q}}(N^2(1-\bar{u}u))| \cdot \mathrm{mn}_S(j;\gamma)^2 = |N_{E/\mathbb{Q}}(D_j)|^2\, |N_{E/\mathbb{Q}}(1-\bar{u}u)| = \|\mathfrak{g}\|_S(\gamma)^2$. Multiplying (3) by $\mathrm{mn}_S(j;\gamma)^2$: for $r \le 1$ the right side is at most $\mathrm{ld}_S(y,v)\,(N^{f(E)}\mathrm{mn}_S(j;\gamma))^2$, and for $r = 2$ it is $\mathrm{ld}_S(y,v)\,\|\mathfrak{g}\|_S(\gamma)^2$. Both are bounded by the maximum. □

LEAN `Filling.minorNorm_sq_le_linkDiscSq_mul`

Proof of Theorem B.

Proof of Theorem B. Write $k_0 = k(\mathfrak{s})$, $k_\gamma = \mathrm{pos}_S(c, c'; \gamma)$, $L_0 = L \cap \ker \mathrm{L}_z(T)$ and $T^\circ = \mathrm{link}^\circ(\gamma, \gamma')$.

Bases. Let m be a matrix whose columns, indexed by a finite set $\mathcal{C}$, are a basis of L_0, and p its part on the rows κ of the first components. The rows z of m vanish, and the link form vanishes on L_0; so $m^* Q_S^{\mathrm{link}} m = p^* p$, and T° is the column span of p, of dimension $\#\mathcal{C}$. By Input 3(c) (with $A = m^* Q_S^{\mathrm{link}}$, whose product with m is invertible by Input 1(c)), extend m by a matrix u to a basis $(m \,|\, u)$ of L with $m^* Q_S^{\mathrm{link}} u = 0$, and then $(m \,|\, u)$ by a matrix y with i columns to a basis of $\mathrm{link}(\gamma)$ with $(m \,|\, u)^* Q_S^{\mathrm{link}} y = 0$ and $yt \in L$ only for $t = 0$. Then $i = k_0 + 1 - \dim L$ by Input 1(a), and if $i = 0$ then $L = \mathrm{link}(\gamma)$. Moreover $\mathrm{L}_z(T) u$ has a left inverse, the columns of u being independent modulo L_0.

Lifts. By Proposition 4.2 there is e with $(\widetilde{m \,|\, u} \,|\, y)e \in \mathrm{IL}(c; \gamma)$, $\mathrm{ld}_S((m \,|\, u \,|\, y), e)\, w_0^2 \le \mathrm{mn}_S(j; \gamma)^2$ and $w_0 = \mathrm{i}_{S,j}(k_\gamma)\mathrm{i}_{S,j}(k_\gamma^{-1})\mathfrak{d}_S(k_\gamma) \neq 0$. Lemma 4.5, applied to $m_1 = (m \,|\, u)$ and y, gives a', v, z with integral lifts of $\tilde{m}_1 a'$ and of $\tilde{m}_1 z + \tilde{y} v$; applied to m and u and the lift $\tilde{m}_1 a'$, it gives a, g_0, z' with integral lifts of $\tilde{m}a$ and of $\tilde{m}z' + \tilde{u}g_0$; and the discriminants multiply:

$$\mathrm{ld}_S(m, a) \cdot \mathrm{ld}_S(u, g_0) \cdot \mathrm{ld}_S(y, v) = \mathrm{ld}_S((m \,|\, u \,|\, y), e). \tag{4}$$

The matrix of the statement of Theorem B is m_1, whose columns span L, with the index set $\mathcal{C} \sqcup \{1, \dots, r\}$, r the number of columns of u.

The part in L_0. Let n be the integral matrix of Lemma 4.4 for $\tilde{m}a$ and c'. Its middle rows are $\mathrm{C}_S^\circ(c)\, \tilde{p}\, a$, its link image is killed by $\mathrm{L}_z(\cdot)$, and its columns are orthogonal to $X + k_\gamma X$; so by Input 1(h) the values $(h(k_\gamma \mathfrak{f}_l, \cdot))_{l < \varrho}$ of its middle part lie in the lattice of the conjugated first ϱ rows of $Z(k_\gamma)$. Input 3(d), with $V = T^\circ$, p, a and $D = [\det(p^* p)]\,[\det a]^2 = \mathrm{ld}_S(m, a) \neq 0$, gives (i) and

$$\big(\mathrm{disc}_{S,c}(T^\circ) \cdot \mathrm{o}_{S,c}(k_\gamma; 1, T^\circ)\big)^2 \;\le\; \mathrm{ld}_S(m, a). \tag{5}$$

The part in L off L_0. Proposition 4.7, for the matrix u, the lift $\tilde{m}z' + \tilde{u}g_0$ (whose image under $\widetilde{\mathrm{L}_z(T)}$ is that of $\tilde{u}g_0$) and the number i (if $i = 0$ then $L = \mathrm{link}(\gamma)$ and hypothesis (a) holds), gives $r \le 1 + (j - \varrho)_+$ and

$$x'^2\, \mathrm{mn}_S(j; \gamma)^2 \;\le\; \mathrm{ld}_S(u, g_0) \cdot \max\big(\|\mathrm{g}\|_S(\gamma), N^{f(E)} \mathrm{mn}_S(j; \gamma)\big)^2. \tag{6}$$

Since $k_0 + 1 = \dim \mathrm{link}(\gamma) = \#\mathcal{C} + r + i$, we get $k_0 \le \dim T^\circ + i + (j - \varrho)_+$.

Assembly. Multiplying (5), (6) and $\mathrm{ld}_S(y, v)$, then using (4) and the bound for the full lift,

$$\begin{aligned}\big(\mathrm{disc}_{S,c}(T^\circ)\mathrm{o}_{S,c}(k_\gamma; 1, T^\circ)\big)^2 x'^2\, \mathrm{mn}_S(j; \gamma)^2\, \mathrm{ld}_S(y, v) &\le \max(\cdots)^2\, \mathrm{ld}_S((m \,|\, u \,|\, y), e) \\ &\le \max(\cdots)^2\, \mathrm{mn}_S(j; \gamma)^2\, w_0^{-2}.\end{aligned}$$

Dividing by $\mathrm{mn}_S(j; \gamma)^2 > 0$ and multiplying by $\mathfrak{d}_S(k_\gamma)^2$, the left side becomes

$$\big(\mathrm{pi}_S(c, c'; \gamma, \gamma')\, x'\big)^2\, \mathrm{ld}_S(y, v),$$

and the right side becomes

$$\max(\cdots)^2 \cdot \big(\mathrm{i}_{S,j}(k_\gamma)\, \mathrm{i}_{S,j}(k_\gamma^{-1})\big)^{-2} = \mathrm{cg}_S(j; c, c'; \gamma)^2. \qquad \square$$

Proof of Theorem A.

Proof of Theorem A. Apply Theorem B to (γ,γ') and to (γ',γ); the space L is the same, so both give the same number $i = k(\mathfrak{s}) + 1 - \dim L$ and the same x'. This gives (i) and (ii) of Theorem A, matrices m, y, v, z for γ and m', y', v', z' for γ', with i columns in y and in y', and

$$\begin{aligned} \big(\mathrm{pi}_S(c,c';\gamma,\gamma')x'\big)^2 \mathrm{ld}_S(y,v) &\le \mathrm{cg}_S(j;c,c';\gamma)^2, \\ \big(\mathrm{pi}_S(c,c';\gamma',\gamma)x'\big)^2 \mathrm{ld}_S(y',v') &\le \mathrm{cg}_S(j;c,c';\gamma')^2. \end{aligned} \tag{7}$$

The pairing of the complements. Let Q_0 be the diagonal matrix with $Q_S^{\mathrm{link}} Q_0 = Q_S^{\pm}$; it satisfies $Q_0^* Q_S^{\pm} = 4\, Q_S^{\mathrm{link}}$ (both are checked on the diagonal entries). We apply Input 2 with $Q = Q_S^{\mathrm{link}}$, $a = g(S)^{-1}y$, $a' = Q_0 y'$, v, v' and $x_0 = 1$. Here

$$a^* Q a' = g(S)^{-1} y^* Q_S^{\pm} y', \qquad a^* Q a = g(S)^{-2} y^* Q_S^{\mathrm{link}} y, \qquad a'^* Q a' = 4\, y'^* Q_S^{\mathrm{link}} y',$$

and the determinants of the last two have the absolute norms

$$g(S)^{-4if(E)}\, |N_{E/\mathbb{Q}} \det(y^* Q_S^{\mathrm{link}} y)| \qquad \text{and} \qquad 2^{4if(E)}\, |N_{E/\mathbb{Q}} \det(y'^* Q_S^{\mathrm{link}} y')|.$$

So, once its hypotheses are verified, Input 2 gives

$$1 \;\le\; \Big(\frac{2}{g(S)}\Big)^{4if(E)} \mathrm{ld}_S(y,v) \cdot \mathrm{ld}_S(y',v'). \tag{8}$$

Invertibility. Suppose $y^* Q_S^{\pm} y'\, t = 0$. The vector $y't$ lies in $\mathrm{link}(\gamma')$, which is isotropic for the link form and contains L; so $y't$ is orthogonal to the columns of m and of y, which span $\mathrm{link}(\gamma)$. As the link is Lagrangian (Input 1(a)), $y't \in \mathrm{link}(\gamma)$, hence $y't \in L$ and $t = 0$ by the property of y'.

Integrality. Let (t_1, w_1) and (t_2, w_2) be lift data for $\tilde{m}z + \tilde{y}v$ and for $\tilde{m}'z' + \tilde{y}'v'$. The columns of m, m' lie in L, which is orthogonal for the link form to $\mathrm{link}(\gamma)$ and to $\mathrm{link}(\gamma')$; so

$$v^*\, \widetilde{y^* Q_S^{\pm} y'}\, v' = (\tilde{m}z + \tilde{y}v)^*\, \widetilde{Q_S^{\pm}}\, (\tilde{m}'z' + \tilde{y}'v') = w_1^*\, t_1^*\, J_S(1 \widetilde{-\gamma\gamma'^{-1}}) t_2\, w_2,$$

the last step by Input 1(b) with the coefficients 1, 1. In the coordinates of the lattice of c this is $(\mathrm{C}_S(c)\tilde{t}_1 w_1)^* J_f (1-\kappa_0)(\mathrm{C}_S(c)\tilde{t}_2 w_2)$ with $\kappa_0 = \mathrm{pos}_S(c,c;\gamma\gamma'^{-1})$; as $\gamma\gamma'^{-1}$ is a term over $(c,1,c)$, $g(S)^{-1}(1-\kappa_0)$ is integral (Input 1(g)), and the other factors are integral. Hence the matrix $v^*\, \widetilde{a^* Q a'}\, v'$ is integral, and if its determinant δ is a unit then $1 \le [\delta]$.

Conclusion. Multiplying the two inequalities (7) and using (8),

$$\big(\mathrm{pi}_S(c,c';\gamma,\gamma')\mathrm{pi}_S(c,c';\gamma',\gamma)\, x'^2\big)^2 \le \Big(\frac{2}{g(S)}\Big)^{4if(E)} \big(\mathrm{cg}_S(j;c,c';\gamma)\mathrm{cg}_S(j;c,c';\gamma')\big)^2,$$

and all the quantities are non-negative; taking square roots gives (iii). □

5 Where the results are used

Theorems A and B (the latter for its part (i)) and Corollary 4.3 are used in the crude estimate of the note on the energy of amplitude sums of this unit, in the estimate of the pairs of terms of one level (Input 3 of Note F); Corollary 4.3 is used also in the modules on thin classes and on the block bound. Proposition 4.2, Lemmas 4.1, 4.4, 4.5, 4.6 and Proposition 4.7 are used only inside this module. Nothing of this note is used directly by the filling theorem.

6 Notes on the formal text

1. *Arguments that the census reads differently from Lean; to be settled by* `#check` *on a build.* In Lemma 4.4 the formal statement names the index set of the columns of m, a variable of the file, so Lean takes it as an argument although the census does not list it; it is the set $\mathcal{C}$ of the statement here. For Theorem B the census lists a variable of the file for a matrix, its index set and the finiteness of that set; the statement introduces its own matrix m after "there are", and Lean takes none of the three. They have no counterpart in the statement of Theorem B.
2. *Statements cut by the census.* The statements of Lemma 4.1, Proposition 4.2, Lemma 4.4 and Theorem B contain local definitions at which the census ends the statement; they were read to their true end, with the second reader's table of corrected spans.
3. *The columns of the bordered matrix.* In Lemma 4.1 the columns are γe_a for $a < j$ and e_a^* for $a \geq j$, as the code selects them; the comment of the source says $a \leq j$ and $a > j$. The second reader of the dossier had noted this.
4. *The matrix m of Theorem B* spans $L = \mathrm{link}(\gamma) \cap \mathrm{link}(\gamma')$, not its part in $\ker \mathrm{L}_z(T)$; the latter appears only in the proof.
5. *Truncated differences.* $(j - \varrho(\mathfrak{s}))_+$ and $k(\mathfrak{s}) + 1 - \dim L$ are differences of natural numbers in the formal text; the first is 0 or 1, and the second is not truncated since $\dim L \leq k(\mathfrak{s}) + 1$.
6. *Exponents computed here.* In Proposition 4.2 the powers of N in Jacobi's identity cancel exactly: $[N]^{\#B+2} \cdot [N]^{-\#B} = [N]^2 = N^{4f(E)}$, the square of the factor in Lemma 4.1. In Theorem A the factor $(2/g(S))^{2if(E)}$ is the square root of $g(S)^{-4if(E)} \cdot 2^{4if(E)}$, the absolute norms of $g(S)^{-2i}$ and of 4^i. In Proposition 4.7 the case $r = 2$ uses $|N_{E/\mathbb{Q}}(N^2)| = N^{4f(E)}$, which cancels the normalisation of $\mathrm{mn}_S(\varrho + 1; \gamma)$.
7. *What was not re-derived.* One passage is stated as the formal text has it and was not derived again for this note: the two divisibilities of Step 4 of Proposition 4.2. All other steps are proved in the text from the inputs. In Lemma 4.1 the formal text reorders the rows and columns of the bordered matrix and verifies its block form entry by entry; the note gives the three lines that this verification amounts to.
8. *The threshold x* of "fixes norm at least x" is a natural number in the formal text; in the inequalities of Theorems A and B and of Proposition 4.7 it is read as a real number.

9. *Input 4.* The formal statement is about an integral matrix and its plain products with the frame and its image; the note states it for the pairings of the hermitian form, as it is applied.

How this note was written. From the structured proofs of the module on link pairings in the fourth chunk of the unit's dossier, which a second reader had re-read completely. I read the module in the Lean text line by line and compared every statement of this note with it argument by argument; I read in the Lean text the definitions recalled in §2. The inputs are stated from the dossier's readings of their quoted statements; of them I read in the Lean text only the definitions they involve. The block form of the bordered matrix in Lemma 4.1 is written as the referee of this note gave it. Arguments that are mine and replace matrix computations of the formal text: the evaluation of $\det A$ in Lemma 4.1 by a rank-one update, the block identity in Step 3 of Proposition 4.2, the two identities (2), the exclusion of $r = 2$ for $j \le \varrho$, and the computation of the pairing in Theorem A. Nothing was compiled for this note. The program check of the unit's dossier covered 1371 leaf steps of 179 proofs.

Appendix A. Concordance with the Lean artifact

The formal names of the objects and the letters of this note: `link`, `commonLink` and `linkMatrix` are $\mathrm{link}(\gamma)$, $\mathrm{link}^{\circ}(\gamma,\gamma')$ and $\mathrm{L}(\gamma)$; `framePair` and `isotropicFramePair` are $[\mathfrak{f} \mid \gamma\mathfrak{f}]$ and $[\mathfrak{e} \mid \gamma\mathfrak{e}]$; `linkForm`, `linkMetric`, `zFormPair` are $Q_S^{\pm}$, Q_S^{link}, $\mathrm{L}_z(T)$; `linkDiscSq`, `minorNorm`, `classGauge`, `pairInvariant`, `termDiscNorm` are $\mathrm{ld}_S(v,e)$, $\mathrm{mn}_S(j;\gamma)$, $\mathrm{cg}_S(j;c,c';\gamma)$, $\mathrm{pi}_S(c,c';\gamma,\gamma')$, $\|\mathrm{g}\|_S(\gamma)$; `xRowsIndex`, `saturationIndex`, `latticeDisc`, `frameValueIndex` are $\mathrm{i}_{S,j}(k)$, $\mathfrak{d}_S(k)$, $\mathrm{disc}_{S,c}(V)$, $\mathrm{o}_{S,c}(k;a,V)$; `HasIntegralLifts`, `HasLevel` are $m \in \mathrm{IL}(c;\gamma)$, $\gamma \in \mathrm{Lv}_j(S)$; `classCoord`, `classCoordX₀` are $\mathrm{C}_S(c)$, $\mathrm{C}^{\circ}_S(c)$; `genIndex` is $[\xi]$. Two statements as the artifact has them:

Notation

E, τ, x_τ, $f(E)$, $N_{E/\mathbb{Q}}$ a CM field with its CM type, an infinite place, the image at it, the number of infinite places, the norm

$\mathbb{A}_{E,f}$, $\hat{O}_E$, $\tilde{a}$, $[\xi]$ finite adeles, integral adeles, the image of a matrix over E, the generalised index

$\mathfrak{s} = (\varrho, \kappa, k_0)$ a shape; $\varrho(\mathfrak{s})$, $k(\mathfrak{s})$, $I(\mathfrak{s})$, $M(\mathfrak{s})$; j a level; in proofs ϱ, k_0 abbreviate $\varrho(\mathfrak{s})$, $k(\mathfrak{s})$

e_a, e_a^*, z, $\mathfrak{f}_a$, X basis vectors, the frame, the span of the e_a; h the hermitian form

S filling data: $N(S)$ (also N), $g(S)$, $\mathsf{G}(S)$, $\mathrm{Cl}(S)$, $G_S(E)$, G_S^{lat}, $K(S)$, red_S, $K_g(S)$

T, $T_S^{\mathrm{rat}}(E)$, $T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})$, J_S, J_f the middle form and the split Gram matrices, rational and in the lattice basis

c, c', s, t, γ, γ' classes, elements of $\mathsf{G}(S)$, rational elements

$\mathrm{pos}_S(c, c'; \gamma)$, $\mathrm{Tm}_S(c, s, c')$, k, k_γ, κ_0 position, terms; positions in proofs

$Z_S(\gamma)$, $Z(k)$, $Z_X(k)$, $D_l(Z)$, D_j, D frame Gram matrices, their first rows, leading minors

$\mathfrak{g}_S(\gamma)$, $\|\mathfrak{g}\|_S(\gamma)$ term discriminant and the product of its absolute values

$[\mathfrak{f} \mid \gamma\mathfrak{f}]$, $[\mathfrak{e} \mid \gamma\mathfrak{e}]$, $\mathrm{L}(\gamma)$, $\mathrm{link}(\gamma)$, $\mathrm{link}^\circ(\gamma, \gamma')$ frame pair, isotropic frame pair, link matrix, link, common link; the italic L, L_0 and T° are subspaces in the proof of Theorem B (the upright L belongs to the link matrix and to $\mathrm{L}_z(T)$)

$\mathrm{L}_z(T)$, $Q_S^{\pm}$, Q_S^{link}, Q_0 the z-pairings, link form, link metric, a diagonal matrix

$\mathrm{ld}_S(v, e)$, $\mathrm{mn}_S(j; \gamma)$, $\mathrm{cg}_S(j; c, c'; \gamma)$, $\mathrm{pi}_S(c, c'; \gamma, \gamma')$ squared discriminant, minor norm, gauge, invariant of a pair

$\mathrm{C}_S(c)$, $\mathrm{C}_S^\circ(c)$, $m \in \mathrm{IL}(c; \gamma)$ class coordinates; integral lifts, for the filling data S of the setting

$\mathrm{i}_{S,j}(k)$, $\mathfrak{d}_S(k)$, $\mathrm{disc}_{S,c}(V)$, $\mathrm{o}_{S,c}(k; a, V)$, $\mathrm{i}(F)$, w_0 indices and discriminants of lattices

$\gamma \in \mathrm{Lv}_j(S)$, $\mathrm{pl}_j(Z)$, υ level; the padded leading matrix; the scalar of a normal form; $s \in \mathrm{Agr}(S)$, $\mathrm{fix}(s) \geq x$ the predicates "agrees" and "fixes norm at least x"

P, M, A, Z', B, F, p', Q, u, n, a, e, z_1 matrices of Lemma 4.1 and Proposition 4.2; here P is a matrix, not the parameters

$\mathcal{C}$, $\mathcal{C}'$, m, y, v, z, f, d, r, i, w, x, x', x_0 index sets, matrices and numbers of the statements

ε, ε_1, ε_2, u', a', ς_0, δ the two link vectors, a selection of rows, a determinant, in Proposition 4.7

p, g_0, z', m_1, m', y', v', t_1, t_2, w_1, w_2 in the proofs of Theorems B and A

J, c_0, d_p, V, q, l, b, D_0, O, G, K, U, R, H, I, $\mathrm{fm}(k)$, n_X, n_M in the inputs and as stated where they occur; GL, $\mathbb{Q}$

READBACK NOTE 41

The filling data: Bessel subgroups, links of frames, Siegel's lemma and strong approximation

One unit of the Lean artifact grh-compact, read back into mathematics: Note S of the unit on the filling theorem

Summary. The filling theorem behind Theorem B of the write-up (*enough forms*) is a second moment of Poincaré series on a unitary group of signature $(\varrho + k, \varrho + 1)$ at every infinite place of a CM field E, built from Bessel functions along the subgroup $\mathcal{S} = \mathcal{U}\mathcal{H}$ that is unitriangular on a frame of ϱ isotropic vectors and one negative vector. This note sets the stage. It defines the record of the *filling data* with its standing hypotheses, the groups, double cosets, terms, cutoffs and amplitudes of the second moment, and the abstract inputs from the real places (Bessel systems, sieve systems). It then proves the tools of the later notes: the dictionary between rational, finite adelic and real coordinates; that the *link* of two frames is a Lagrangian subspace and an invariant of the double coset of $\mathcal{U}$; Siegel's lemma for hermitian lattices, with the convergence of a height zeta function of subspaces; strong approximation for $\mathcal{U}$; and that a term in the Bessel subgroup with trivial reduction is unipotent, by the freeness of the classes.

What this note is. The artifact grh-compact is a body of Lean code whose final theorems state the Riemann hypothesis and its analogue for Dirichlet L-functions. That is a claim: its authors report that Lean's kernel accepts the code, a replay of that check by the owner of this write-up is recorded elsewhere, and nothing was compiled for this note; no mathematician has read the proof through. This note treats the first part of one unit (the folder of the filling theorem): 232 of its 497 declarations, the content of nine files. Three further notes of the same writer treat the rest of the first half of the unit: Note B (*Box partitions of arithmetic unipotent groups*), Note E (*The energy of amplitude sums*) and Note U (*Poincaré series of cut Bessel functions*); the second half has four notes of another writer: Note F (the filling theorem), Note P (the pairing of links), Note T (the top floor at a finite place) and Note G (from amplitude sums to local correlations). This note is Note S; the eight notes cite each other by these letters. Every statement was compared, argument by argument, with the Lean text. Proofs are complete at the level of a research paper, with these exceptions, each said where it occurs: results of other units and of the background library are quoted as *Inputs*; identities between explicit matrices that the formal text checks entry by entry are stated and not recomputed; and the argument lists that the census of the artifact reads from the text differ from Lean's for some declarations (Section 8). The Lean text read is that of commit `72fead10`; Appendix A is the concordance of 232 declarations.

1 The statements

The notions are defined in Section 2; here is what they are in a few words. A *shape* $\mathfrak{s} = (\varrho, \kappa, k_0)$ fixes a hermitian space with basis $e_0, \dots, e_{\varrho-1}$; x_i $(i \in \kappa)$; z; $e^*_{\varrho-1}, \dots, e^*_0$, in which e_a and e^*_a are dual isotropic vectors and the middle part, spanned by the x_i and z, carries a form T. The *frame* is $(\mathfrak{f}_0, \dots, \mathfrak{f}_\varrho) = (e_0, \dots, e_{\varrho-1}, z)$. The group $\mathcal{U}(T)$ is the unipotent radical of the stabilizer of the flag of the e_a, the group $\mathcal{H}(T)$ fixes all e_a, e^*_a and z, and $\mathcal{S}(T) = \mathcal{U}(T)\mathcal{H}(T)$ is the Bessel subgroup. Filling data S over a CM field E single out the form $T^{\mathrm{rat}}_S(E) = \mathrm{diag}(1, \dots, 1, -N(S))$, a lattice, two primes $q_0(S), q_1(S)$ with product $g(S)$ and the principal congruence subgroup $K_g(S)$ of level $g(S)$ in the finite adelic group G^{lat}_S.

Theorem A (strong approximation for the unipotent group). *(a)* Let E be a number field that is a CM field, $\mathfrak{s}$ a shape, T an $\mathfrak{s}$-form over E that is hermitian and invertible, and T' an $\mathfrak{s}$-form over the finite adeles $\mathbb{A}_{E,f}$ such that $J(T')$ is the image of $J(T)$ under $E \to \mathbb{A}_{E,f}$. Then $\mathcal{U}(T')$ is contained in the closure, in $G(T')$, of the image of $\mathcal{U}(T)$ under the homomorphism $G(T) \to G(T')$ that embeds every entry.
(b) Let E be a CM field with a CM type, $\mathfrak{s}$ a shape and $S \in \mathrm{Fill}(E, \mathfrak{s})$. For every $x \in G^{\mathrm{lat}}_S$ with $x \in \mathcal{U}(T^{\mathrm{lat}}_S(\mathbb{A}_{E,f}))$ and every $y \in G^{\mathrm{lat}}_S$ there is a rational element $u \in \mathcal{U}(T^{\mathrm{rat}}_S(E))$ such that $y^{-1}\,(x^{-1}\,\mathrm{r}^f_S(u))\,y \in K_g(S)$.

Theorem B (the link of two frames). *(a)* Let F be a commutative ring with involution, $\mathfrak{s}$ a shape, T an $\mathfrak{s}$-form over F and $\gamma, u, u' \in G(T)$ with $u \in \mathcal{U}(T)$ and $u' \in \mathcal{U}(T)$. Then $\mathrm{link}(u^{-1}\gamma u') = \mathrm{link}(\gamma)$.
(b) Let E be a CM field with a CM type, $\mathfrak{s}$ a shape, $S \in \mathrm{Fill}(E, \mathfrak{s})$, $\gamma \in G_S(E)$ and $p \in E^{M(\mathfrak{s})} \times E^{M(\mathfrak{s})}$. Then $p \in \mathrm{link}(\gamma)$ if and only if $q^*\,Q^{\pm}_S\,p = 0$ for every $q \in \mathrm{link}(\gamma)$: the link is its own orthogonal complement for the form $Q^{\pm}_S$ of signature zero.

Theorem C (Siegel's lemma for hermitian lattices; a height zeta function). Let E be a CM field with a CM type that is stably unramified, κ a finite set, and $u \in G_f(E,\kappa)$ an element of the finite adelic unitary group of the standard form. Write $\|X\| = \big(\sum_\tau \sum_{i\in\kappa} |(X_i)_\tau|^2\big)^{1/2}$ for $X \in E^\kappa$, the sum over the infinite places τ of E, and $\mathrm{disc}_{u^{-1}}(V)$ for the discriminant of the lattice of the adelic points of a subspace $V \subseteq E^\kappa$ that lie in $u\,\hat{O}_E^\kappa$ (Definition 2.28).
(a) Let $V \subseteq E^\kappa$ be a subspace and s a natural number with $\dim_E V + s = \#\kappa$. Then there are vectors $X_1, \dots, X_s \in E^\kappa$, all non-zero and in $u\,\hat{O}_E^\kappa$, such that V is the set of the $v \in E^\kappa$ with $\sum_{i\in\kappa} \overline{(X_j)_i}\, v_i = 0$ for $j = 1, \dots, s$, and

$$\Big(\prod_{j=1}^{s} \|X_j\|\Big)^{2f(E)} \;\le\; \big(8\, f(E)\, s\ \mathrm{rd}_E\big)^{f(E)s} \cdot \mathrm{disc}_{u^{-1}}(V).$$

(b) For every natural number s,

$$\sum_{\substack{V\subseteq E^\kappa \\ \dim_E V + s = \#\kappa}} \mathrm{disc}_{u^{-1}}(V)^{-(\#\kappa+1)} \;\le\; \big(200\, f(E)\, \#\kappa\ \mathrm{rd}_E\big)^{f(E)(\#\kappa+1)s}.$$

Theorem D (terms in the Bessel subgroup). Let E be a CM field with a CM type, $\mathfrak{s}$ a shape and $S \in \mathrm{Fill}(E,\mathfrak{s})$ admissible filling data.
(a) Let $c, d \in \mathrm{Cl}(S)$ and $\gamma \in G_S(E)$ with $\gamma \in \mathcal{S}(T_S^{\mathrm{rat}}(E))$ and $\mathrm{pos}_S(c,d;\gamma) \in K_g(S)$. Then $c = d$ and $\gamma \in \mathcal{U}_{S,c}$.
(b) Let $c \in \mathrm{Cl}(S)$ and $s \in \overline{\mathcal{S}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))}^{\,S}$. Then there are a class $d \in \mathrm{Cl}(S)$ and an element $\gamma \in \mathcal{S}(T_S^{\mathrm{rat}}(E))$ with $\gamma \in \mathrm{Tm}_S(c,s,d)$.
(c) Let $c, c', d \in \mathrm{Cl}(S)$, $s \in \mathsf{G}(S)$ and $\gamma, u \in G_S(E)$ with $\gamma \in \mathrm{Tm}_S(c,s,c')$, $u \in \mathrm{Tm}_S(c,s,d)$ and $\gamma \mathfrak{f}_a = u \mathfrak{f}_a$ for all frame vectors. Then $c' = d$ and $\gamma^{-1}u \in \mathcal{U}^0_{S,c'}$.

Theorem E (the dictionary). Let E be a CM field with a CM type, $\mathfrak{s}$ a shape and $S \in \mathrm{Fill}(E,\mathfrak{s})$.
(a) $K_g(S)$ is the group of the $k \in G_S^{\mathrm{lat}}$ such that k and k^{-1} have entries in $\hat{O}_E$ and all entries of $\hat{g}(S)^{-1}(k-1)$ lie in $\hat{O}_E$.
(b) Let $k \in G_f(E,\kappa)$, where κ is the index set of $\mathfrak{s}$. Then $\mathrm{inc}_S(k) \in K(S)$ if and only if k and k^{-1} have entries in $\hat{O}_E$ and the row k_0 of $k-1$ has entries in $\bar{\pi}(S)\,\hat{O}_E$.
(c) Let σ be a side, $x \in G_S(\mathbb{A}_E)$ with $x \in \mathcal{U}(T_S^{\mathrm{rat}}(\mathbb{A}_E))$, and $y \in G_\infty(E,\mathfrak{s})$. Then, as vectors indexed by $\mathrm{Bc}(S)$,

$$W_S^\sigma(\mathrm{a}_S^\infty(x)\, y)_{\cdot} = \frac{\psi_E\big(-(g(S)\,\varpi(S))^{-1}\,\mathrm{sd}(x)\big)}{\psi_S^{\mathcal{U}}(\mathrm{a}_S^f(x))}\, W_S^\sigma(y)_{\cdot},$$

where ψ_E is the standard additive character of $\mathbb{A}_E$.

Theorem A is the classical strong approximation theorem for a unipotent group, in the form needed here (the artifact names Platonov and Rapinchuk [2] for it); part (b) feeds Theorem D and the construction of Poincaré series in Note U. Theorem B

is used in Note E to sort the terms of the second moment by their links. Theorem C counts subspaces by the discriminants of their lattices; the sum in (b) is what makes the contribution of degenerate terms small. Theorem D identifies the terms that lie in the Bessel subgroup, and Theorem E translates between the three systems of coordinates in which the data are written.

2 The setting

Conventions. Rings are commutative with 1. A *ring with involution* is a commutative ring with a ring automorphism $x \mapsto \overline{x}$ of order at most two; letters R, R', F, A, C denote such rings (each statement says which structure it uses), and M^* is the conjugate transpose of a matrix M, M^{t} its transpose. All index sets κ, Ω, P, m, n, I of matrices are finite. A *shape* is denoted $\mathfrak{s}$, an $\mathfrak{s}$-form T or T', and $\gamma, \gamma', \delta, u, u', s, s', x, y, \sigma_0, \sigma_1$ are elements of the groups named in the statements; p, q are sequences of units; j, l, a, b, i are indices and c, c', c'', d classes or ring elements, as each statement says. E is a number field that is a CM field: a totally complex quadratic extension of a totally real field, with complex conjugation $x \mapsto \overline{x}$. A *CM type* of E is the choice, for every infinite place τ of E, of an embedding $E \to \mathbb{C}$ inducing τ; the image of $x \in E$ is written x_τ. When E has a CM type we say *CM field with a CM type*. S always denotes filling data over E for $\mathfrak{s}$ (Definition 2.15); in statements about S the field E and the shape $\mathfrak{s}$ are those of S. A *side* is one of the two words full, cut, and σ denotes a side. Measures on locally compact groups are Haar measures, fixed by the formal text; integrals of functions with values in $[0, \infty]$ are Lebesgue integrals with values in $[0, \infty]$. The letters S, s, σ, q, ψ, ζ have in the notes of this unit the meanings given here, not those of the overview of the write-up (there: a set of columns, the complex variable, a field automorphism, a rational number, a column, Riemann's function). For the filling data of admissible data (Note G), the primes $q_0(S)$, $q_1(S)$ are the primes that the overview calls g_0, g_1, and $g(S)$ is their product.

Adeles. For a CM field E with ring of integers O_E: $\mathbb{A}_E$ is the ring of adeles, $\mathbb{A}_{E,f}$ the ring of finite adeles, $\hat{O}_E \subset \mathbb{A}_{E,f}$ the closure of O_E, a compact open subring. Complex conjugation acts on $\mathbb{A}_{E,f}$ and on the set of finite places $w \mapsto \overline{w}$; $\mathbb{F}_w$ is the residue field at w, q_w its number of elements, and $\hat{O}_E \to \mathbb{F}_w$ the reduction modulo w. The number of infinite places is $f(E)$, the discriminant d_E, the root discriminant $\mathrm{rd}_E = |d_E|^{1/(2f(E))}$, and $\mathrm{vol}(\hat{O}_E) = 2^{f(E)}/\sqrt{|d_E|}$. The standard additive character ψ_f of $\mathbb{A}_{E,f}$ is $\psi_f(x) = e^{2\pi i \,\mathrm{Tr}_{E/\mathbb{Q}}(a)}$ for any $a \in E$ with $x - a \in \hat{O}_E$, and $\psi_E(x) = e^{-2\pi i \sum_\tau 2\,\mathrm{Re}\, x_\tau}\, \psi_f(x_f)$ is the standard additive character of $\mathbb{A}_E$. For a unit a of $\mathbb{A}_{E,f}$ (or of a finite product of local fields), $[a]$ is the *generalized index*: the inverse of the factor by which multiplication by a scales Haar measure, equal to the index $[\hat{O}_E : a\hat{O}_E]$ when $a \in \hat{O}_E$; it is 0 at non-units. E is *stably unramified* if it contains a primitive root of unity of order 5040.

Setting 2.1 (shapes, forms, groups; background)**.** A *shape* $\mathfrak{s} = (\varrho, \kappa, k_0)$ is a natural number ϱ, a finite set κ and an element $k_0 \in \kappa$. Put $k(\mathfrak{s}) = \#\kappa$, $n(\mathfrak{s}) = \varrho + 1$, $M(\mathfrak{s}) = \kappa \sqcup \{z\}$ (the *middle indices*), and let $I(\mathfrak{s})$ be the disjoint union of $\{0, \dots, \varrho - 1\}$,

$M(\mathfrak{s})$ and a second copy of $\{0,\dots,\varrho-1\}$; its $r(\mathfrak{s}) = 2\varrho + k(\mathfrak{s}) + 1$ elements index a basis written

$$e_0,\dots,e_{\varrho-1};\qquad x_i\ (i\in\kappa),\ z;\qquad e^*_{\varrho-1},\dots,e^*_0.$$

The *frame* is $\mathfrak{f}_a = e_a$ for $a<\varrho$ and $\mathfrak{f}_\varrho = z$. The *level* of a basis vector is $\mathrm{lev}(e_a)=a$, $\mathrm{lev}(x_i)=\mathrm{lev}(z)=\varrho$, $\mathrm{lev}(e^*_a)=2\varrho-a$, and its *floor* is $\mathrm{fl}(e_a)=\mathrm{fl}(e^*_a)=a$, $\mathrm{fl}(z)=\varrho$, $\mathrm{fl}(x_i)=\varrho+1$.

Let R be a ring. An $\mathfrak{s}$-*form* over R is a square matrix T over R indexed by $M(\mathfrak{s})$; for $N\in R$, $T^{\mathrm{rat}}(\mathfrak{s};N)$ is the diagonal $\mathfrak{s}$-form with entries 1 on κ and $-N$ at z. The *split Gram matrix* $J(T)$, indexed by $I(\mathfrak{s})$, has the entries 1 at (e_a,e^*_a) and (e^*_a,e_a), the block T on $M(\mathfrak{s})$, and 0 elsewhere. If R has an involution, $G(T)$ is the group of the invertible matrices g over R indexed by $I(\mathfrak{s})$ with $g^*\,J(T)\,g = J(T)$, and $h_T(v,w) = v^*\,J(T)\,w$. For the form $T^{\mathrm{rat}}(\mathfrak{s};1)$ over $\mathbb{C}$ the group is $G_1(\mathfrak{s})$, a unitary group of signature $(\varrho+k(\mathfrak{s}),\varrho+1)$. Subgroups of $G(T)$:

- $\mathcal{U}(T)$: the g with $g_{ij}=\delta_{ij}$ whenever $\mathrm{lev}(j)\le\mathrm{lev}(i)$ (unitriangular for the blocks of equal level);
- $\mathcal{U}^0(T)$: the $g\in\mathcal{U}(T)$ with $g\mathfrak{f}_a=\mathfrak{f}_a$ for all $a\le\varrho$;
- $\mathcal{H}_l(T)$, for a natural number l: the g whose column j is that of 1 whenever $\mathrm{fl}(j)<l$; and $\mathcal{H}(T)=\mathcal{H}_{\varrho+1}(T)$, which fixes all e_a, e^*_a and z;
- $\mathcal{S}(T)$, the *Bessel subgroup*: the g with $g_{i\,\mathfrak{f}_a}=\delta_{i\,\mathfrak{f}_a}$ for all $a\le\varrho$ and all i with $\mathrm{lev}(i)\ge\mathrm{lev}(\mathfrak{f}_a)$, that is, $g\mathfrak{f}_a-\mathfrak{f}_a\in\mathrm{span}(e_b : b<a)$.

For a matrix γ indexed by $I(\mathfrak{s})$, the *frame Gram matrix* is the square matrix of size $\varrho+1$

$$Z_T(\gamma) = \big((J(T)\gamma)_{\mathfrak{f}_a,\mathfrak{f}_b}\big)_{a,b\le\varrho} = \big(h_T(\mathfrak{f}_a,\gamma\mathfrak{f}_b)\big)_{a,b},$$

and for $y\in G_1(\mathfrak{s})$ we write $Z(y)$ for the frame Gram matrix of y for $T^{\mathrm{rat}}(\mathfrak{s};1)$. For a square matrix Z and l at most its size, $\mathrm{D}_l(Z)$ is the determinant of its upper left $l\times l$ block. For $s\in G(T)$, $\mathrm{sd}(s)=\sum_{a<\varrho} s_{\mathfrak{f}_a,\mathfrak{f}_{a+1}}$. For $v\in R^{\varrho+1}$ we write $\mathfrak{f}v=\sum_a v_a\mathfrak{f}_a$ and $(\gamma\mathfrak{f})v=\gamma(\mathfrak{f}v)$. For a sequence p of units of R and $l\le\varrho$, the *Weyl element* $w_l(p)\in G(T)$ maps $e_a\mapsto p_a e^*_a$ and $e^*_a\mapsto \overline{p_a}^{-1}e_a$ for $a<l$ and fixes the other basis vectors.

The following facts about these groups are used throughout; the formal text proves them in its background library.

Inputs (groups). In Setting 2.1, let R be a ring with involution and T an $\mathfrak{s}$-form over R. (G1), unit 112: if d is an invertible matrix that is block upper triangular for the levels and u is unitriangular for the levels, then $d^{-1}ud$ is unitriangular for the levels. (G2), unit 1: $\mathcal{S}(T)$ normalizes $\mathcal{U}(T)$; $\mathrm{sd}(hu) = \mathrm{sd}(h) + \mathrm{sd}(u)$ for $h, u \in \mathcal{S}(T)$; $\mathrm{sd}(h) = 0$ for $h \in \mathcal{H}(T)$. (G3), units 119 and 1: $\mathcal{U}(T) \subseteq \mathcal{S}(T)$ and $\mathcal{H}(T) \subseteq \mathcal{S}(T)$; if $J(T)$ is hermitian and invertible, then $s \in \mathcal{S}(T)$ if and only if $s = uh$ with $u \in \mathcal{U}(T)$ and $h \in \mathcal{H}(T)$. For $T = T^{\mathrm{rat}}(\mathfrak{s}; N)$ and g in the unitary group $\mathrm{U}_\kappa(R)$ of the identity matrix on κ, let $\iota_N(g) \in G(T)$ act as g on the x_i and fix the other basis vectors; then $\iota_N(g) \in \mathcal{H}(T)$, and if N is a unit every $h \in \mathcal{H}(T)$ is $\iota_N(g)$ for some g; if moreover $J(T)$ is hermitian and invertible and R has an element t with $t + \bar{t} = 1$, every $s \in \mathcal{S}(T)$ is $u\,\iota_N(g)$ with $u \in \mathcal{U}(T)$ and $g \in \mathrm{U}_\kappa(R)$. (G4), unit 119: for $u, u' \in \mathcal{U}(T)$ and $\gamma \in G(T)$, every leading minor satisfies $\mathrm{D}_l(Z_T(u^{-1}\gamma u')) = \mathrm{D}_l(Z_T(\gamma))$; and $Z_T(\gamma) = \mathfrak{f}^*\, J(T)\, \gamma \mathfrak{f}$. (G5), unit 120: for $u \in \mathcal{U}(T)$, $u\mathfrak{f}_b - \mathfrak{f}_b \in \mathrm{span}(\mathfrak{f}_a : a < b)$ for all $b \le \varrho$ (the matrix of u on the frame is upper unitriangular), and the entries of u in the rows of $M(\mathfrak{s})$ and of the e_a^* and the columns of the e_a and of $M(\mathfrak{s})$ are those of 1: u preserves $X = \mathrm{span}(e_a)$ and acts trivially on $X^\perp/X$. (G6), unit 29: for $g \in G(T)$, $J(T)\, g^{-1} = g^*\, J(T)$ and $h_T(gv, gw) = h_T(v, w)$.

The lattice form and the lattice basis.

Definition 2.2 (lattice form, lattice basis)**.** Let $\mathfrak{s} = (\varrho, \kappa, k_0)$ be a shape and R a ring.

(i) For $N \in R$, $T^{\mathrm{lat}}(\mathfrak{s}; N)$ is the $\mathfrak{s}$-form with diagonal entries 1 at the $i \in \kappa$, $i \neq k_0$, 0 at k_0 and $-N$ at z, with entries -1 at (k_0, z) and (z, k_0), and 0 elsewhere.

(ii) Let R have an involution and let p be a unit of R. The matrix $\Lambda^\circ(\mathfrak{s}; p)$, with rows indexed by $M(\mathfrak{s})$ and columns by κ, has the rows $i \in \kappa$ of the diagonal matrix with $\overline{p}$ at k_0 and 1 elsewhere, and its row z has the entry $-p^{-1}$ in column k_0 and 0 elsewhere.

(iii) With R and p as in (ii), $\Lambda(\mathfrak{s}; p)$ is the invertible matrix indexed by $I(\mathfrak{s})$ that is the identity on the e_a and e_a^* and whose middle block has the columns x_i $(i \neq k_0)$, $v = \overline{p}^{-1} x_{k_0} + (p\overline{p})^{-1} z$ in the place of x_{k_0}, and z. Its inverse has the middle block $(\Lambda^\circ(\mathfrak{s}; p) \mid z)$: in the basis x_i $(i \neq k_0)$, v, z one has $x_{k_0} = \overline{p}\, v - p^{-1} z$.

LEAN `latMiddleGram` · `middleBaseChange` · `besselLatticeBasis`

So $T^{\mathrm{lat}}(\mathfrak{s}; N)$ is the Gram matrix of the form $T^{\mathrm{rat}}(\mathfrak{s}; N)$ in the basis x_i $(i \neq k_0)$, v, z when $N = p\overline{p}$: the vector v is isotropic, $h(v, z) = -1$ and $h(z, z) = -N$.

Lemma 2.3. *Let $\mathfrak{s}$ be a shape.* (a) *Let R be a ring with involution, p a unit of R and $N \in R$ with $p\,\overline{p} = N$. Then*

$$\Lambda(\mathfrak{s}; p)^*\ J(T^{\mathrm{rat}}(\mathfrak{s}; N))\ \Lambda(\mathfrak{s}; p) = J(T^{\mathrm{lat}}(\mathfrak{s}; N)).$$

(b) *Let A be a ring with involution, $R \subseteq A$ a subring and $N \in A$ with $N \in R$ and $\overline{N} = N$. Then $T^{\mathrm{lat}}(\mathfrak{s}; N)$ is* unimodular over *R: it is hermitian, and it and its inverse have entries in R.*

Proof. (a) Both sides are the identity pairing on the e_a, e_a^*, so only the middle block matters. There the columns of $\Lambda(\mathfrak{s}; p)$ are x_i $(i \neq k_0)$, v, z, and $h(x_i, x_j) = \delta_{ij}$,

$h(x_i, v) = 0$ for $i \neq k_0$, $h(x_i, z) = 0$, $h(v, v) = (p\overline{p})^{-1} - N(p\overline{p})^{-2} = 0$, $h(v, z) = -N(p\overline{p})^{-1} = -1$, $h(z, z) = -N$. (b) The form is symmetric with entries $0, \pm 1, -N$ fixed by the involution. Its inverse is the matrix with 1 at the diagonal places $i \neq k_0$, with N at (k_0, k_0), -1 at (k_0, z) and (z, k_0), and 0 at (z, z), that is $T^{\mathrm{lat}}(\mathfrak{s}; 0)$ plus N at (k_0, k_0): on the plane of k_0 and z the product of $\left(\begin{smallmatrix} 0 & -1 \\ -1 & -N \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} N & -1 \\ -1 & 0 \end{smallmatrix}\right)$ is 1. Both have entries in R. □

LEAN `gram_besselLatticeBasis` · `isUnimodular_latMiddleGram`

The frame discriminant, frame pairs and the link.

Definition 2.4 (frame discriminant)**.** Let R be a ring with involution, $\mathfrak{s}$ a shape, $N \in R$ and Z a square matrix over R of size $\varrho + 1$. Then

$$\mathrm{g}(N; Z) = \det Z \cdot \overline{\det Z} - N^2 \, \mathrm{D}_\varrho(Z) \cdot \overline{\mathrm{D}_\varrho(Z)}.$$

LEAN `frameDisc`

Definition 2.5 (frame pairs, link)**.** Let R be a ring with involution, $\mathfrak{s}$ a shape, T an $\mathfrak{s}$-form over R and $\gamma \in G(T)$.

(i) $[\mathfrak{f} \mid \gamma\mathfrak{f}]$ is the matrix with $2(\varrho + 1)$ columns $\mathfrak{f}_0, \dots, \mathfrak{f}_\varrho, \gamma\mathfrak{f}_0, \dots, \gamma\mathfrak{f}_\varrho$, and $[\mathfrak{e} \mid \gamma\mathfrak{e}]$ the matrix with the 2ϱ columns $e_0, \dots, e_{\varrho-1}, \gamma e_0, \dots, \gamma e_{\varrho-1}$.

(ii) $\mathrm{L}(\gamma)$ is the matrix of the linear map $R^{I(\mathfrak{s})} \to R^{M(\mathfrak{s})} \times R^{M(\mathfrak{s})}$, $t \mapsto (t_{\mathrm{mid}}, (\gamma^{-1}t)_{\mathrm{mid}})$, where t_{mid} denotes the coordinates of t at the middle indices.

(iii) The *link* of γ is the submodule

$$\mathrm{link}(\gamma) = \left\{ \mathrm{L}(\gamma)\, t \;:\; t \in R^{I(\mathfrak{s})},\ [\mathfrak{e} \mid \gamma\mathfrak{e}]^* \, J(T)\, t = 0 \right\} \;\subseteq\; R^{M(\mathfrak{s})} \times R^{M(\mathfrak{s})}.$$

LEAN `framePair` · `isotropicFramePair` · `linkMatrix` · `link`

With $X = \mathrm{span}(e_0, \dots, e_{\varrho-1})$, the condition on t says $t \perp X$ and $t \perp \gamma X$, and for such t both t and $\gamma^{-1}t$ lie in $X^\perp$, whose quotient by X is the middle space. So $\mathrm{link}(\gamma)$ is the set of the pairs (class of t, class of $\gamma^{-1}t$) in $(X^\perp/X)^2$, for $t \perp X + \gamma X$. Three unfoldings are used below without mention: $\mathfrak{f}v$ has the e-coordinates $v_0, \dots, v_{\varrho-1}$, the z-coordinate v_ϱ and no other; $(\gamma\mathfrak{f})v = \gamma(\mathfrak{f}v)$; and for a hermitian invertible matrix J every row vector l is v^*J for $v = (lJ^{-1})^*$, so every linear form is $h(v, \cdot)$.

LEAN `frameImage_one_mulVec` · `frameImage_mulVec` · `exists_star_vecMul_eq`

Sieve systems. The local theory at the real places and at the finite places produces, floor by floor, a family of positive kernels. Their common shape is the following; it is used in Note U and in the notes of the second half.

Definition 2.6 (damped powers, head weights)**.** *(i)* For a natural number k and a real number r, $\mathrm{dp}_k(r) = r^k \cdot \min(1, r)^6$.

(ii) For natural numbers K, i and a sequence $p = (p_0, p_1, \dots)$ of non-zero complex numbers, $\Lambda_K^{\mathbb{C}}(i; p) = \prod_{l<i} \mathrm{dp}_K(|p_0 p_1 \cdots p_l|^{-1})$.

(iii) Let A be a finite product of non-archimedean local fields with its ring of integers O_A (in the formal text: a ring satisfying the axioms of such a product). For natural numbers K, i and a sequence p of units of A, with $D_l = p_0 p_1 \cdots p_l$,

$$\Lambda_K(i; p) = \prod_{l<i} \begin{cases} \sqrt{[D_l]}^{\,K} & \text{if } D_l \in O_A, \\ 0 & \text{otherwise.} \end{cases}$$

LEAN dampedPower · headWeight · finHeadWeight

For a sequence p, an index i and an element x we write $p[i \mapsto x]$ for the sequence p with its entry of index i replaced by x.

Definition 2.7 (sieve system)**.** Let C be a ring with a measure and U a topological space. Let $u\colon C \to U$ and $\iota\colon U \to C$ be maps, n a natural number, $J = (J_i)_{i\in\mathbb{N}}$ a family of functions $J_i\colon U^{\mathbb{N}} \times U^{\mathbb{N}} \to \mathbb{C}$, $\psi\colon C \to \mathbb{C}$ a function, En a real number, $\Lambda = (\Lambda_i)_{i\in\mathbb{N}}$ a family of functions $\Lambda_i\colon U^{\mathbb{N}} \to \mathbb{R}$ and $\beta\colon C \to \mathbb{R}$ a function. We write $\mathrm{Sieve}(u, \iota, n, J, \psi, En, \Lambda, \beta)$, and say that these data are a *sieve system* on C, if:

(S1) $\psi(0) = 1$;

(S2) for all $i \le n$, all $p, q \in U^{\mathbb{N}}$ and all $\xi \in C$, the function $f(c) = \psi(\xi c)\, J_{i+1}(p[i \mapsto u(c)], q[i \mapsto u(c)])$ on C is integrable; if $\xi = 0$ then $\int_C f = J_i(p, q)$; and if ξ is a unit of C then $|\int_C f| \le \beta(\xi)\, \Lambda_i(p)\, \Lambda_i(q)$;

(S3) for every finite set Ω, every family $(a_k)_{k\in\Omega}$ in $U^{\mathbb{N}}$ and every $t \in U$ with $(a_k)_n = t$ for all k, the matrix $\big(J_{n+1}(a_k, a_l)\big)_{k,l\in\Omega}$ is positive semidefinite;

(S4) J_{n+1} is continuous on $U^{\mathbb{N}} \times U^{\mathbb{N}}$;

(S5) $|J_0(p, q)| \le En$ for all p, q;

(S6) for all $i < n$ and all p, q such that $\xi = \iota(p_i) - \iota(q_i)$ is a unit of C, $|J_{i+1}(p, q)| \le \beta(\xi)\, \Lambda_{i+1}(p)\, \Lambda_{i+1}(q)$.

LEAN SieveSystem

So J_i is obtained from J_{i+1} by integrating over a common entry of index i (S2, $\xi = 0$), the top form is a positive kernel in the remaining variables (S3), and non-trivial frequencies and unequal entries are small (S2, S6). On $\mathbb{C}$ the standard choices are $u(c) = c$ for $c \neq 0$ and $u(0) = 1$, with values in $\mathbb{C}^\times$, which we write $u_{\mathbb{C}}$, and $\psi(c) = e^{c-\bar{c}}$, which we write $\mathbf{e}$.

Proposition 2.8 (products of sieve systems)**.** *Let C be a ring with an s-finite measure, U a topological space, Ω a finite set, and let K be a sieve system $\mathrm{Sieve}(u, \iota, n, J, \psi, En, \Lambda, \beta)$ on C. Let $\iota'\colon \mathbb{C}^\times \to \mathbb{C}$ be a map, $\Lambda' = (\Lambda'_i)_i$ a family of functions $(\mathbb{C}^\times)^{\mathbb{N}} \to \mathbb{R}$, and for every $v \in \Omega$ let J'_v, En'_v and $\beta'_v\colon \mathbb{C} \to \mathbb{R}$ be such that H_v is a sieve system $\mathrm{Sieve}(u_{\mathbb{C}}, \iota', n, J'_v, \mathbf{e}, En'_v, \Lambda', \beta'_v)$ on $\mathbb{C}$. Then*

$$\mathrm{Sieve}(u^+, \iota^+, n, J^+, \psi^+, En^+, \Lambda^+, \beta^+)$$

holds on the ring $\mathbb{C}^\Omega \times C$ with the product measure, where, for $x = ((x_v)_v, x_C)$ and for sequences p in $(\mathbb{C}^\times)^\Omega \times U$ with components $p^{(v)}$ and $p^{(C)}$,

$$u^+(x) = \big((u_{\mathbb{C}}(x_v))_v, u(x_C)\big), \qquad \iota^+(y) = \big((\iota'(y_v))_v, \iota(y_U)\big),$$
$$J_i^+(p, q) = \prod_v J'_{v,i}(p^{(v)}, q^{(v)}) \cdot J_i(p^{(C)}, q^{(C)}), \qquad \psi^+(x) = \prod_v \mathbf{e}(x_v) \cdot \psi(x_C),$$
$$\Lambda_i^+(p) = \prod_v \Lambda'_i(p^{(v)}) \cdot \Lambda_i(p^{(C)}), \qquad \beta^+(x) = \prod_v \beta'_v(x_v) \cdot \beta(x_C),$$

and $En^+ = \prod_v En'_v \cdot En$.

Proof. (S1) holds since $\mathbf{e}(0) = 1$ and $\psi(0) = 1$. A unit of $\mathbb{C}^\Omega \times C$ is a tuple of units. For (S2), the function attached to (i, p, q, ξ) is the product, in independent variables, of the functions attached to $(i, p^{(v)}, q^{(v)}, \xi_v)$ for H_v and to $(i, p^{(C)}, q^{(C)}, \xi_C)$ for K.

Each factor is integrable, hence so is the product, and by Fubini's theorem (the measures are s-finite) its integral is the product of the integrals of the factors. For $\xi = 0$ this is $J_i^+(p,q)$; for a unit ξ every factor is bounded by its own (S2), and the product of the bounds is $\beta^+(\xi)\Lambda_i^+(p)\Lambda_i^+(q)$. For (S3), the matrix $(J_{n+1}^+(a_k,a_l))_{k,l}$ is the entrywise product of the matrices of the factors, which are positive semidefinite because the components of the a_k share their entries of index n; by Schur's product theorem, applied $\#\Omega$ times, it is positive semidefinite. (S4) holds because products of continuous functions composed with projections are continuous. (S5) and (S6) follow by multiplying the bounds of the factors, all of them non-negative; in (S6), $\iota^+(p_i) - \iota^+(q_i)$ is a unit exactly when all its components are. □

LEAN `SieveSystem.pi`

Lemma 2.9 (one step, summed)**.** *Let C be a ring with a measure, U a topological space, Ω a finite set, and let K be a sieve system* $\mathrm{Sieve}(u,\iota,n,J,\psi,En,\Lambda,\beta)$ *on C. Let $i \le n$ and let $(a_p)_{p\in\Omega}$ be a family in $U^{\mathbb{N}}$. Put $F(c) = \sum_{p,q\in\Omega} J_{i+1}(a_p[i \mapsto u(c)], a_q[i \mapsto u(c)])$. Then F is integrable, $\int_C F = \sum_{p,q} J_i(a_p,a_q)$, and for every unit ξ of C, $|\int_C \psi(\xi c)F(c)\,dc| \le \beta(\xi)\big(\sum_p \Lambda_i(a_p)\big)^2$.*

Proof. Sum (S2) over the pairs (p,q), once with $\xi = 0$, where $\psi(0) = 1$ by (S1), and once with the given unit; note $\sum_{p,q}\Lambda_i(a_p)\Lambda_i(a_q) = \big(\sum_p \Lambda_i(a_p)\big)^2$. □

LEAN `SieveSystem.step_sum`

Proposition 2.10 (positivity and semicontinuity on every floor)**.** *Let C be a ring with a measure and a first countable topology, U a topological space, Ω a finite set, and let K be a sieve system* $\mathrm{Sieve}(u,\iota,n,J,\psi,En,\Lambda,\beta)$ *on C. Let $i \le n$, let $b\colon C \to (U^{\mathbb{N}})^\Omega$ and $c\colon C \to U$ be maps such that $(b(x)_p)_i = c(x)$ for all $x \in C$ and $p \in \Omega$, and put $F(x) = \sum_{p,q\in\Omega} J_{i+1}\big(b(x)_p, b(x)_q\big)$. Then $F(x)$ is a non-negative real number for every x, and F is lower semicontinuous at every point x at which all the maps $x' \mapsto b(x')_p$ are continuous.*

Proof. Downward induction on i, for all b and c at once. For $i = n$, $F(x)$ is the value at the vector $(1,\dots,1)$ of the hermitian form with matrix $(J_{n+1}(b(x)_p, b(x)_q))_{p,q}$, which is positive semidefinite by (S3), the sequences sharing the entry $c(x)$ of index n; and F is continuous at x by (S4), hence lower semicontinuous there. Let $i < n$ and suppose the claim for $i+1$ and all families. For $z \in C$ put $b^z(x)_p = b(x)_p[i+1 \mapsto u(z)]$. These sequences share their entry $u(z)$ of index $i+1$, and $x' \mapsto b^z(x')_p$ is continuous where $x' \mapsto b(x')_p$ is. By the induction hypothesis $F^z(x) = \sum_{p,q} J_{i+2}\big(b^z(x)_p, b^z(x)_q\big)$ is non-negative for all x, and lower semicontinuous in x at the points in question. By Lemma 2.9 with the index $i+1 \le n$ and the family $(b(x)_p)_p$, the function $z \mapsto F^z(x)$ is integrable and $\int_C F^z(x)\,dz = F(x)$. So $F(x) \ge 0$. If $x_k \to x$, then by Fatou's lemma and the semicontinuity of the F^z,

$$\begin{aligned} F(x) = \int_C F^z(x)\,dz &\le \int_C \liminf_k F^z(x_k)\,dz \\ &\le \liminf_k \int_C F^z(x_k)\,dz = \liminf_k F(x_k); \end{aligned}$$

since the topology of C is first countable, this is lower semicontinuity at x. The hypothesis on the common entry of index i is used only for $i = n$. □

LEAN `SieveSystem.nonneg_and_lowerSemicontinuous`

Eichler maps in the unipotent group. For a hermitian matrix J with form $h(v,w) = v^* J w$, vectors x, v and a scalar ς, the *Eichler map* is $w \mapsto w + x\,h(v,w) - (v+\varsigma x)\,h(x,w)$.

> **Input (E1)**, unit 119. If J is hermitian, $h(x,x) = 0$, $h(v,x) = 0$ and $\varsigma + \bar{\varsigma} = h(v,v)$, then the Eichler map of (x, v, ς) is an isometry of h.

Proposition 2.11 (Eichler maps along the frame)**.** *Let A be a ring with involution that has an element t with $t + \bar{t} = 1$, $\mathfrak{s}$ a shape and T an $\mathfrak{s}$-form over A such that $J(T)$ is hermitian and invertible. Let $a \le \varrho$ be a frame index, $j \in A^{\varrho+1}$ with $j_b = 0$ for all $b \ge a$, and $r \in A$. Let $v \in A^{I(\mathfrak{s})}$ and let $m = v^* J(T)$ be the linear form $h_T(v,\cdot)$, and suppose $m(\mathfrak{f}_b) = 0$ for all $b < a$. Then there is $u \in \mathcal{U}(T)$ with*

$$\mathrm{sd}(u) = r \sum_{b=1}^{\varrho} m(\mathfrak{f}_b)\, j_{b-1},$$

whose matrix is the Eichler map of $(r\,\mathfrak{f} j,\ v,\ t\,h_T(v,v))$.

Proof. Put $x = r\,\mathfrak{f} j = r\sum_{b<a} j_b \mathfrak{f}_b$ and $\varsigma = t\,h_T(v,v)$. Since $a \le \varrho$, x lies in $\mathrm{span}(e_b : b < a)$, which is isotropic, and $h_T(v,x) = m(x) = r\sum_{b<a} j_b m(\mathfrak{f}_b) = 0$. As $J(T)$ is hermitian, $h_T(v,v)$ is fixed by the involution, so $\varsigma + \bar{\varsigma} = (t+\bar{t})h_T(v,v) = h_T(v,v)$. By (E1) the Eichler map u lies in $G(T)$. The form $h_T(x,\cdot)$ vanishes on all basis vectors except the e_b^* with $b < a$, and the $e_{b'}^*$-coordinate of v is $h_T(e_{b'}, v) = \overline{m(\mathfrak{f}_{b'})} = 0$ for $b' < a$. So the matrix $(v+\varsigma x)\,h_T(x,\cdot)$ has non-zero entries only in columns e_b^*, $b < a$, and in rows other than the $e_{b'}^*$ with $b' < a$: these rows have smaller level than the column. The matrix $x\,m$ has non-zero entries only in rows e_c, $c < a$, and its entry at a column of level $\le c$, a vector $e_{c'}$ with $c' \le c$, is $x_c\, m(\mathfrak{f}_{c'}) = 0$. Hence $u \in \mathcal{U}(T)$. Finally $h_T(x, \mathfrak{f}_{b+1}) = 0$ for all $b < \varrho$, so $\mathrm{sd}(u) = \sum_{b<\varrho} x_{\mathfrak{f}_b}\, m(\mathfrak{f}_{b+1}) = r\sum_{b<\varrho} j_b\, m(\mathfrak{f}_{b+1})$. □

The constant $c_G(\mathfrak{s})$ is positive, being a quotient of positive numbers. For $k \ge 1$ its second factor is $\mathrm{vol}\,\mathrm{U}(k)/\mathrm{vol}\,\mathrm{U}(k-1)$.

Definition 2.13 (correlations, Schur bounds, band limits)**.** Let $\mathfrak{s}$ be a shape, I a finite set and $W\colon G_1(\mathfrak{s}) \to \mathbb{C}^I$ a function.

(i) For a group G with a measure μ, a function $W\colon G \to \mathbb{C}^I$ and $\gamma \in G$, $\mathrm{J}(\mu, W;\gamma) \in \mathbb{C}^{I\times I}$ is the vector with the coordinates $\int_G W(y)_i\,\overline{W(\gamma^{-1}y)_{i'}}\,d\mu(y)$, $(i,i') \in I \times I$.

(ii) For $D \in [0,\infty]$, $\mathrm{Sch}(W) \le D$ means: for every integrable $\varphi\colon G_1(\mathfrak{s}) \to \mathbb{C}$,

$$\int \Big\| \int_{G_1(\mathfrak{s})} \varphi(y)\,W(\gamma y)\,dy \Big\|^2 d\mu_{\mathcal{U}\backslash G}(\gamma) \;\le\; D \int_{G_1(\mathfrak{s})} |\varphi(y)|^2\,dy.$$

(iii) For a homomorphism rep from $\mathrm{U}_\kappa(\mathbb{C})$ to the unitary group of $\mathbb{C}^I$, a real number B and $D \in [0,\infty]$, $\mathrm{SchB}(W,\mathrm{rep};B,D)$ means: there are continuous functions $V_w\colon G_1(\mathfrak{s}) \to \mathbb{C}^I$, one for each finite list w of pairs of elements of $I(\mathfrak{s})$, with $V_\emptyset = W$, such that for every w: V_w is a Bessel function for rep; for every curve $g\colon \mathbb{R} \to G_1(\mathfrak{s})$, every matrix X and every real t with $g'(t) = g(t)X$, the function $V_w \circ g$ has at t the derivative $\sum_{a,b\in I(\mathfrak{s})} X_{ab}\,V_{(a,b)w}(g(t))$; and if the length $|w|$ is at most $2n^2$, then $\mathrm{Sch}(V_w) \le B^{2|w|}D$.

(iv) For $y \in G_1(\mathfrak{s})$ and a sequence p of non-zero complex numbers,

$$\mathrm{J}^\circ(y;W,p) = \frac{\sqrt{c_G(\mathfrak{s})}\,\sqrt{|p_\varrho|^2-1}^{\,k-1}}{\#I} \prod_{a<\varrho} |p_a|^{k+1+2(\varrho-a-1)} \cdot \mathrm{J}(\mathrm{vol}, W; w_\varrho(p)\,y),$$

with vol the Haar measure of $G_1(\mathfrak{s})$.

(v) For real numbers b, $\deg$ and a family $J = (J_i)_i$ of functions on pairs of sequences of non-zero complex numbers, $\mathrm{BL}(b,W,\deg,J)$ means: $\mathrm{Sieve}(u_{\mathbb{C}},\, x \mapsto x^{-1},\, \varrho, J, \mathbf{e}, (1+b^{-10})/\deg, \Lambda, \beta)$ holds on $\mathbb{C}$ with $\Lambda_i(p) = \Lambda^{\mathbb{C}}_{n^6}(i;p)$ and $\beta(\xi) = c_{\mathrm{band}}(\mathfrak{s})\,b^{2000n^9}\,\mathrm{dp}_{k-n^7}(|\xi|^{-1})$; and for every $\sigma_0 \in \mathcal{H}_\varrho(T^{\mathrm{rat}}(\mathfrak{s};1))$ and all p, q with $p_\varrho = Z(\sigma_0)_{\varrho\varrho}$ and $q_\varrho = p_\varrho$,

$$J_n(p,q) = \big\langle \mathrm{J}^\circ(\sigma_0;W,p),\ \mathrm{J}^\circ(\sigma_0;W,q)\big\rangle.$$

LEAN `besselCorrelation` · `SchurLe` · `HasSchurBound` · `normCorrelation` · `HasBandLimits`

In (iii) the function $V_{(a,b)w}$ is the derivative of V_w along the elementary matrix E_{ab} acting on the right; in (v), $Z(\sigma_0)_{\varrho\varrho} = h(z,\sigma_0 z)$, and the inner product is that of $\mathbb{C}^{I\times I}$, conjugate linear in the first variable.

Definition 2.14 (sides, cut pairs, Bessel systems)**.** Let $\mathfrak{s}$ be a shape.

(i) A *side* is one of the two values full and cut. In the formal text a side is an ambient argument, with full as its default value.

(ii) Let I be a finite set, b a real number, f a natural number, rep a homomorphism from $\mathrm{U}_\kappa(\mathbb{C})$ to the unitary group of $\mathbb{C}^I$, and $W = (W^{\mathrm{full}}, W^{\mathrm{cut}})$ a pair of continuous functions $G_1(\mathfrak{s}) \to \mathbb{C}^I$. Then $\mathrm{CP}(b, f, \mathrm{rep}, W)$ is the conjunction of: W^{full} and W^{cut} are Bessel functions for rep; W^{full} is integrable for $\mu_{\mathcal{U}\backslash G}$; $\int \|W^{\mathrm{full}}\|^2 d\mu_{\mathcal{U}\backslash G} = \#I$; $\int \|W^{\mathrm{cut}}\|^2 d\mu_{\mathcal{U}\backslash G} \le \#I$; $W^{\mathrm{cut}}(y) \neq 0$ implies $y \in \mathrm{Cut}(b)$; $\int \|W^{\mathrm{cut}} - W^{\mathrm{full}}\|^2 d\mu_{\mathcal{U}\backslash G} \le (b^{-5r^2})^2\, \#I$; and there are a measurable function $A \colon G_1(\mathfrak{s}) \to [0,\infty]$, invariant under left translation by $\mathcal{U}(T^{\mathrm{rat}}(\mathfrak{s}; 1))$, and a finite measure m on $G_1(\mathfrak{s})$ with

$$\epsilon(y)\,\|W^\sigma(y)\| \le A(y) \le \mathsf{m}\{g : yg \in \mathrm{Cut}(b)\} \quad \text{for all } y \text{ and both sides } \sigma,$$
$$\mathsf{m}(G_1(\mathfrak{s}))\ \int A\, d\mu_{\mathcal{U}\backslash G} \le b^{2r^3}\, \#I,$$

where $\epsilon(y) = 1$ if $W^{\mathrm{full}}(y) = W^{\mathrm{cut}}(y)$ and $\epsilon(y) = b^{3r^3 f}$ otherwise.

(iii) For a real number b and a natural number f, a *Bessel system* $\mathfrak{B} \in \mathrm{BSys}(\mathfrak{s}, b, f)$ is a record of: a non-empty finite set I; a pair $W = (W^{\mathrm{full}}, W^{\mathrm{cut}})$ of continuous functions $G_1(\mathfrak{s}) \to \mathbb{C}^I$; a real number $\deg > 0$; a homomorphism rep from $\mathrm{U}_\kappa(\mathbb{C})$ to the unitary group of $\mathbb{C}^I$; and a family J as in Definition 2.13(v); such that $\mathrm{CP}(b, f, \mathrm{rep}, W)$ holds; every matrix that commutes with all $\mathrm{rep}(h)$ is scalar; $\mathrm{SchB}(W^{\mathrm{full}}, \mathrm{rep}; P, \deg^{-1}\#I)$ for every real $P \ge b^5$; $8\,r \le b$; and $\mathrm{BL}(b, W^{\mathrm{cut}}, \deg, J)$.

LEAN `Side` · `IsCutPair` · `BesselSystem`

Bessel systems are constructed, from discrete series representations, in the notes on the real place (unit 132) and used here only through this record.

The filling data. For a CM field E and a finite set κ: $G_f(E,\kappa)$ is the unitary group of the identity matrix on κ over $\mathbb{A}_{E,f}$ (the matrices g with $g^* g = 1$), $K_f(E,\kappa)$ its subgroup of the matrices that have entries in $\hat{O}_E$ together with their inverses, and $\Gamma_f(E,\kappa)$ the image of $\mathrm{U}_\kappa(E)$ in $G_f(E,\kappa)$. A *level* is an open subgroup of $G_f(E,\kappa)$ contained in $K_f(E,\kappa)$. For a shape $\mathfrak{s}$, $G_\infty(E,\mathfrak{s})$ is the product of copies of $G_1(\mathfrak{s})$ over the infinite places of E, with the product of the Haar measures.

Definition 2.15 (filling data)**.** Let E be a CM field with a CM type and $\mathfrak{s} = (\varrho, \kappa, k_0)$ a shape; write $k = k(\mathfrak{s})$, $n = n(\mathfrak{s})$, $f = f(E)$. *Filling data* $S \in \mathrm{Fill}(E, \mathfrak{s})$ are a record of

- a natural number $N(S)$; two natural numbers $q_0(S)$, $q_1(S)$; a unit $\bar{\pi}(S)$ of $\mathbb{A}_{E,f}$; an integer $\varpi(S) \in O_E$; a real number $b(S)$;
- two finite sets $\mathrm{Ch}_0(S)$, $\mathrm{Ch}_1(S)$ of finite places of E, the *chosen places*;
- a level $K^{\mathrm{col}}(S) \subseteq G_f(E,\kappa)$, the *column level*;
- for every infinite place τ of E a Bessel system $\mathfrak{B}_\tau(S) \in \mathrm{BSys}(\mathfrak{s}, b(S), f)$, whose components we write $I_\tau(S)$, $W^\sigma_{S,\tau}$, $\deg_\tau(S)$, $\mathrm{rep}_{S,\tau}$;

subject to the following conditions, in which $b = b(S)$, $N = N(S)$, $q_i = q_i(S)$, $\bar{\pi} = \bar{\pi}(S)$:

(F1) $\Gamma_f(E,\kappa) \cap g\, K^{\mathrm{col}}(S)\, g^{-1} = 1$ for every $g \in G_f(E,\kappa)$;

(F2) $\bar{\pi}\cdot\overline{\bar{\pi}} = N$ in $\mathbb{A}_{E,f}$; N is a prime number; $\bar{\pi}\in\hat{O}_E$; and for every finite place w, either $\bar{\pi}$ is a unit at w, or $q_w = N$ and $\bar{\pi}$ is a unit at $\overline{w}$;

(F3) q_0 and q_1 are prime numbers different from N, with $b^{10}\le q_i\le b^{11}$;

(F4) every $w\in \mathrm{Ch}_i(S)$ has $q_w = q_i$; the sets $\mathrm{Ch}_0(S)$ and $\mathrm{Ch}_1(S)$ are disjoint; if w is chosen then $\overline{w}$ is not; and each $\mathrm{Ch}_i(S)$ has f elements;

(F5) for every $x\in\hat{O}_E$: q_0q_1 divides x in $\hat{O}_E$ if and only if x and $\overline{x}$ reduce to 0 modulo every chosen place;

(F6) $\overline{\varpi(S)} = -\varpi(S)$, and the different of E is the ideal generated by $\varpi(S)$;

(F7) $10^5\le\varrho$; $2^{-\varrho}\le b^{-6}$; $(\varrho+1)[E:\mathbb{Q}]\le 2^{2\varrho}$; $1000(2\varrho+2)^9\le k$; $1000(2\varrho+2)\le k$; $k\le f$; $10^{10}n^4\le n^6$, $3n^6+12\le n^7$ and $n^7\le k$;

(F8) $(200\,f\,k\,\mathrm{rd}_E)^{1000}\le b$; $f\le b/1000$; $k\le b$; $\mathrm{rd}_E\le b$; $\varrho+1\le b$; $1000\le b$; $1\le b$; $b^{19}\le q_0q_1\le b^{23}$; $5\le N$.

LEAN Filling

Definition 2.16 (forms and groups of the data)**.** Let $S\in\mathrm{Fill}(E,\mathfrak{s})$ and let R be a ring.

(i) $g(S) = q_0(S)\cdot q_1(S)$.

(ii) $T_S^{\mathrm{rat}}(R) = T^{\mathrm{rat}}(\mathfrak{s};N(S))$ and $T_S^{\mathrm{lat}}(R) = T^{\mathrm{lat}}(\mathfrak{s};N(S))$, with $N(S)$ read in R.

(iii) If R has an involution, $G_S(R) = G(T_S^{\mathrm{rat}}(R))$. Further $G_S^{\mathrm{lat}} = G(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, the finite adelic group *in the lattice basis*.

(iv) $\mathsf{G}(S) = \prod_{i\in\{0,1\}}\prod_{w\in\mathrm{Ch}_i(S)}\mathrm{GL}_{I(\mathfrak{s})}(\mathbb{F}_w)$, a finite group.

(v) $\mathrm{Bc}(S) = \prod_\tau I_\tau(S)$, the product over the infinite places.

(vi) $\mathrm{Cl}(S) = \Gamma_f(E,\kappa)\backslash G_f(E,\kappa)/K^{\mathrm{col}}(S)$, the set of *classes*. It is finite and non-empty; every class c has a chosen representative $\dot{c}\in G_f(E,\kappa)$.

(vii) For $\gamma\in G_S(E)$, $Z_S(\gamma) = Z_{T_S^{\mathrm{rat}}(E)}(\gamma)$ and $\mathfrak{g}_S(\gamma) = \mathfrak{g}(N(S);Z_S(\gamma))$.

LEAN Filling.g · Filling.ratMiddle · Filling.latMiddle · Filling.G · Filling.GFin · Filling.GRes · Filling.BesselCoord · Filling.Classes · Filling.frameProducts · Filling.termDisc

So $Z_S(\gamma) = (h(\mathfrak{f}_a,\gamma\mathfrak{f}_b))_{a,b}$ for the form h of signature $(\varrho+k,\varrho+1)$ at every infinite place, and $\mathfrak{g}_S(\gamma) = |\mathrm{D}_{\varrho+1}(Z)|^2 - N(S)^2|\mathrm{D}_\varrho(Z)|^2$ with $Z = Z_S(\gamma)$ and $|x|^2 = x\overline{x}$.

Definition 2.17 (the integral subgroup and its reduction)**.** Let $S\in\mathrm{Fill}(E,\mathfrak{s})$.

(i) $K(S)$ is the subgroup of the $k\in G_S^{\mathrm{lat}}$ that have entries in $\hat{O}_E$ together with their inverses.

(ii) $\mathrm{red}_S\colon K(S)\to\mathsf{G}(S)$ is the homomorphism that reduces every entry modulo each chosen place.

(iii) $K_g(S)\subseteq G_S^{\mathrm{lat}}$ is the kernel of red_S, the *principal level*.

(iv) For a subgroup $A\subseteq G_S^{\mathrm{lat}}$, $\overline{A}^{\,S} = \mathrm{red}_S(A\cap K(S))$.

(v) $\hat{g}(S)$ is the integer $g(S)$ as a unit of $\mathbb{A}_{E,f}$.

LEAN Filling.latStabilizer · Filling.reduction · Filling.principalLevel · Filling.reducedImage · Filling.gIdele

Definition 2.18 (scales at the infinite places)**.** Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, τ an infinite place of E, a a natural number and $i \in I(\mathfrak{s})$.

(i) $\kappa_\tau(S) = \mathrm{Re}(g(S)\,\varpi(S)_\tau/(2\pi i))$.

(ii) With $s_a = \kappa_\tau(S)^{\varrho-a}/\sqrt{N(S)}$: $\mathrm{sc}_{S,\tau}(i)$ is s_a for $i = e_a$, 1 for $i = x_j$, $s_\varrho = 1/\sqrt{N(S)}$ for $i = z$, and s_a^{-1} for $i = e_a^*$; and $\mathrm{Sc}_{S,\tau}$ is the invertible diagonal complex matrix with the entries $\mathrm{sc}_{S,\tau}(i)$.

(iii) $\mathrm{fs}_S(\tau, a) = \kappa_\tau(S)^{2(\varrho-a)}/N(S)$, and $\mathrm{fs}(S) = \prod_\tau \prod_{a=0}^{\varrho} \mathrm{fs}_S(\tau, a)^{\,k+2(\varrho-a)}$, with $k = k(\mathfrak{s})$.

Definition 2.25 (reduction above g, fixers)**.** Let $S \in \mathrm{Fill}(E,\mathfrak{s})$.

(i) For a ring F and a truth value ϵ, adj_S^ϵ is the automorphism of the group of invertible matrices over F indexed by $I(\mathfrak{s})$ that is the identity if ϵ is false, and $s \mapsto J^{-1}\,(s^{-1})^{\mathrm{t}}\,J$ with $J = J(T_S^{\mathrm{lat}}(F))$ if ϵ is true.

(ii) For $x = ((i,w),\epsilon)$, with $i \in \{0,1\}$, $w \in \mathrm{Ch}_i(S)$ and a truth value ϵ, $\mathrm{red}_{S,x}\colon \hat{O}_E \to \mathbb{F}_w$ is the reduction modulo w, preceded by complex conjugation if ϵ is true.

(iii) For $w \in \mathrm{Ch}_i(S)$ and a pair $d = (\epsilon, v)$ of a truth value and a non-zero vector $v \in \mathbb{F}_w^{\varrho+1}$, $\mathrm{Fix}_{S,w}(d)$ is the subgroup of the $s \in \mathsf{G}(S)$ such that $\mathrm{adj}_S^\epsilon(s_{i,w})$ fixes the vector $\mathfrak{f}v \in \mathbb{F}_w^{I(\mathfrak{s})}$.

(iv) For $s \in \mathsf{G}(S)$ and a natural number x, $\mathrm{fix}(s) \geq x$ means: there is a finite set P of pairs $((i,w),\epsilon)$ as in (ii) with $x \leq \prod_{((i,w),\epsilon)\in P} q_i(S)$, such that for each of them $s \in \mathrm{Fix}_{S,w}((\epsilon, v))$ for some non-zero v.

(v) For a finite set $\Sigma \subseteq \mathrm{Ch}_0(S)$ and a family $d = (d_w)_w$ of pairs as in (iii), $\mathrm{Fix}_S(\Sigma, d)$ is the set of the $s \in \mathsf{G}(S)$ with $s \in \mathrm{Fix}_{S,w}(d_w)$ for all $w \in \Sigma$ and such that either $\Sigma = \mathrm{Ch}_0(S)$, or there is $w \in \mathrm{Ch}_0(S)$ with $\mathrm{D}_l(Z_{T_S^{\mathrm{lat}}(\mathbb{F}_w)}(s_{0,w})) \neq 0$ for all $l \leq \varrho + 1$.

LEAN `Filling.idOrInvAdjoint` · `Filling.reduceAboveG` · `Filling.vectorFixer` · `Filling.FixesNormAtLeast` · `Filling.fixingSet`

The truth value records whether one looks at w or at $\overline{w}$: by Lemma 3.6 the reduction modulo $\overline{w}$ of an element of $K(S)$ is the inverse adjoint of its reduction modulo w. An entry of $\mathrm{red}_S(k)$ depends only on the corresponding entry of k.

LEAN `Filling.reduction_apply_congr`

Definition 2.26 (common links, flag vectors, normal forms)**.** Let R be a ring with involution, $\mathfrak{s}$ a shape, T an $\mathfrak{s}$-form over R and $\gamma, \gamma' \in G(T)$.

(i) $\mathrm{L}_z(T)$ is the matrix with two rows and columns indexed by $M(\mathfrak{s}) \sqcup M(\mathfrak{s})$ that is block diagonal with both blocks equal to the row of T of index z (for this R need not have an involution).

(ii) $\mathrm{link}^\circ(\gamma, \gamma') \subseteq R^\kappa$ is the set of the restrictions $p_1|_\kappa$ of the pairs $(p_1, p_2) \in \mathrm{link}(\gamma) \cap \mathrm{link}(\gamma')$ with $\mathrm{L}_z(T)\,(p_1, p_2) = 0$, that is, with $(Tp_1)_z = (Tp_2)_z = 0$.

(iii) For $c, c' \in R$ and a frame index $a \leq \varrho$, $\mathrm{CF}_a(\gamma; c, c')$ means: there are $x, y \in R^{\varrho+1}$ with $\mathfrak{f}x = (\gamma\mathfrak{f})y$, $x_a = c$, $y_a = c'$, and $x_b = y_b = 0$ for all $b > a$.

(iv) For a natural number j, $\gamma \in \mathrm{NF}_j$ means: there is $c \in R$ with $c\,\overline{c} = 1$ such that $\mathrm{CF}_a(\gamma; c, 1)$ for every frame index $a \geq j$. We then say that γ is in *normal form from* j.

LEAN `Filling.zFormPair` · `commonLink` · `HasCommonFlagVector` · `IsNormalForm`

In words: $\mathrm{CF}_a(\gamma; c, c')$ says that the flags of the frames $\mathfrak{f}$ and $\gamma\mathfrak{f}$ share a vector of the a-th steps with leading coefficients c and c'.

Definition 2.27 (levels, congruent terms, near terms)**.** Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, $c, c' \in \mathrm{Cl}(S)$, $\gamma, \gamma' \in G_S(E)$, $j \in \{0, \dots, \varrho + 1\}$ and i a natural number; write $k = k(\mathfrak{s})$, $f = f(E)$.

(i) $J_S = J(T_S^{\mathrm{rat}}(E))$, and $Q_S^{\pm}$ is the block diagonal matrix with the blocks $T_S^{\mathrm{rat}}(E)$ and $-T_S^{\mathrm{rat}}(E)$, indexed by $M(\mathfrak{s}) \sqcup M(\mathfrak{s})$.

(ii) $\mathrm{cw}_i(S) = \#\overline{\mathcal{S}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))}^{\,S} \cdot \#\mathrm{Cl}(S) \cdot N(S)^{-kf} \cdot \left(2\,\mathrm{tl}(S)^2\right)^i$.

(iii) $\gamma \in \mathrm{Lv}_j(S)$, in words γ *has level* j, means: $\gamma \in \mathrm{NF}_j$, $\mathrm{D}_j(Z_S(\gamma)) \neq 0$, and $\mathfrak{g}_S(\gamma) \neq 0$ if and only if $j = \varrho + 1$.

(iv) $\gamma \sim_{S;c,c'} \gamma'$, in words γ *and* γ' *are congruent terms*, means: there is $s \in \mathsf{G}(S)$ with $\gamma \in \mathrm{Tm}_S(c, s, c')$ and $\gamma' \in \mathrm{Tm}_S(c, s, c')$.

(v) $\|\mathfrak{g}\|_S(\gamma) = \prod_\tau |\mathfrak{g}_S(\gamma)_\tau|$.

(vi) $\mathrm{BxP}(S)$ is the set of the $y \in G_\infty(E, \mathfrak{s})$ with $y_\tau \in \mathrm{FBox}(\mathrm{bx}(S))$ and $y_\tau \in \mathrm{Cut}(b(S))$ for all τ; and $\gamma \in \mathrm{Near}(S)$, in words γ *is near*, means that there is $y \in \mathrm{BxP}(S)$ with $\mathrm{r}_S^\infty(\gamma)^{-1} y \in \mathrm{BxP}(S)$.

(vii) $\gamma \in \mathrm{ChA}(S)$, in words *the characters agree at* γ, means: for all $u, u' \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$ with $u\gamma = \gamma u'$, $\psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u)) = \psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u'))$.

LEAN `Filling.ratGram` · `Filling.linkForm` · `Filling.countWeight` · `Filling.HasLevel` · `Filling.CongruentTerms` · `Filling.termDiscNorm` · `Filling.boxedPoints` · `Filling.IsNear` · `Filling.CharsAgree`

Lattices in subspaces. For a ring A with a subring O and a matrix M over A: M is *integral* if its entries lie in O, *primitive* if it is integral and has an integral left inverse; the *column lattice* of M is the O-module spanned by its columns, its *column space* the A-module they span; the *index* $[L' : L]$ of two O-submodules of A^m is the index of $L \cap L'$ in L', and 0 if that is infinite. Over $\mathbb{A}_{E,f}$ the subring is $\hat{O}_E$.

Definition 2.28 (lattice bases and discriminants of subspaces)**.** Let E be a CM field (a number field for (i)), Ω and P finite sets.

(i) For a matrix M over E, $(M)_{\mathbb{A}_f}$ is the matrix over $\mathbb{A}_{E,f}$ with the same entries.

(ii) Let E be stably unramified, let H be a $P \times \Omega$ matrix over $\mathbb{A}_{E,f}$ with a left inverse L, $LH = 1$, and let $V \subseteq E^\Omega$ be a subspace of dimension s. Then $\mathrm{m}_H(V)$ is a chosen $\Omega \times s$ matrix m over $\mathbb{A}_{E,f}$ such that $H\mathrm{m}$ is primitive over $\hat{O}_E$ and $\mathrm{m} = (y)_{\mathbb{A}_f}\, a$ for a matrix y over E with a left inverse whose columns span V, and an invertible $s \times s$ matrix a over $\mathbb{A}_{E,f}$. (It exists by the Inputs (La1) and (La2) of Section 5.)

(iii) In the situation of (ii), $\mathrm{disc}_H(V) = \sqrt{[\det(\mathrm{m}^*\mathrm{m})]}$ for $\mathrm{m} = \mathrm{m}_H(V)$.

LEAN `Filling.finAdeleMat` · `Filling.sublatticeBasis` · `Filling.sublatticeDisc`

The columns of $\mathrm{m}_H(V)$ are a basis of the lattice of the adelic points v of V with Hv integral; for $H = u^{-1}$ with $u \in G_f(E, \Omega)$ this is $V(\mathbb{A}_{E,f}) \cap u\,\hat{O}_E^\Omega$, the lattice of Theorem C. Two elementary compatibilities are used without mention: $(M^*)_{\mathbb{A}_f} = (M)^*_{\mathbb{A}_f}$; $(aM)_{\mathbb{A}_f} = a(M)_{\mathbb{A}_f}$ for $a \in E$; and for an embedding $\varphi\colon E \to \mathbb{C}$, which commutes with the conjugations because E is a CM field, the matrix of the images of M^* is the conjugate transpose of that of M.

LEAN `Filling.finAdeleMat_conjTranspose` · `Filling.finAdeleMat_smul` · `Filling.map_conjTranspose`

3 First properties and the dictionary

Throughout this section E is a CM field with a CM type, $\mathfrak{s} = (\varrho, \kappa, k_0)$ a shape and $S \in \mathrm{Fill}(E, \mathfrak{s})$; we abbreviate $N = N(S)$, $g = g(S)$, $b = b(S)$, $k = k(\mathfrak{s})$, $n = n(\mathfrak{s})$, $f = f(E)$ in proofs.

Lemma 3.1 (scales)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, τ an infinite place of E, a a natural number, $b \le \varrho$ a frame index and $i \in I(\mathfrak{s})$.*

(a) $\varpi(S) \neq 0$*;* $\kappa_\tau(S) = g(S)\,\varpi(S)_\tau/(2\pi i)$*, so this complex number is real;* $|\kappa_\tau(S)| = g(S)\,|\varpi(S)_\tau|/(2\pi)$*; and* $\kappa_\tau(S) \neq 0$.

(b) $\mathrm{sc}_{S,\tau}(\mathfrak{f}_b) = \kappa_\tau(S)^{\varrho-b}/\sqrt{N(S)}$*;* $\mathrm{sc}_{S,\tau}(i) \neq 0$*;* $\mathrm{fs}_S(\tau, a) > 0$*;* $\mathrm{fs}(S) > 0$*;* $\deg(S) > 0$*; and* $\nu(S) > 0$.

(c) $\mathrm{Sc}^*_{S,\tau}\ J(T_S^{\mathrm{rat}}(\mathbb{C}))\ \mathrm{Sc}_{S,\tau} = J(T^{\mathrm{rat}}(\mathfrak{s}; 1))$.

Proof. (a) The different is a non-zero ideal, so its generator $\varpi(S)$ is not zero (F6). The embedding at τ commutes with complex conjugation, so $\overline{\varpi(S)_\tau} = -\varpi(S)_\tau$ by (F6), and $\varpi(S)_\tau/(2\pi i)$ is real; hence the real part in the definition of $\kappa_\tau(S)$ is the

number itself. The rest follows, $g(S)$ being a product of two primes. (b) The first formula is the definition, and all scales are powers of the non-zero real number $\kappa_\tau(S)$ divided or multiplied by $\sqrt{N(S)} > 0$. Further $\mathrm{fs}_S(\tau, a)$ is the square of a non-zero real number divided by $N(S)$, the degrees of Bessel systems are positive by definition, and $\nu(S)$ is a quotient of positive numbers. (c) The scales are real, with product 1 on each pair e_a, e_a^*, equal to 1 on the x_j and to $1/\sqrt{N(S)}$ on z, where the form has the value $-N(S)$. □

LEAN `Filling.varpi_ne_zero` · `Filling.coe_kappa` · `Filling.abs_kappa_eq` · `Filling.kappa_ne_zero` · `Filling.basisScale_besselFrame` · `Filling.basisScale_ne_zero` · `Filling.frameScaleSq_pos` · `Filling.frameScaleProd_pos` · `Filling.besselDegree_pos` · `Filling.unipCovolume_pos` · `Filling.gram_basisScaleGL`

Part (c) is what makes a_S^∞ take values in $G_\infty(E, \mathfrak{s})$. That $\mathrm{r}_S^{\mathbb{A}}$, a_S^f and the reduction maps are defined uses that a ring homomorphism $R \to R'$ carries $J(T_S^{\mathrm{rat}}(R))$ to $J(T_S^{\mathrm{rat}}(R'))$ and $J(T_S^{\mathrm{lat}}(R))$ to $J(T_S^{\mathrm{lat}}(R'))$, and that it maps a matrix that is the identity at a set of positions to a matrix with the same property; also $T_S^{\mathrm{rat}}(E)$ is hermitian and invertible, and $G_S(E)$ is countable.

Lemma 3.2 (coordinates)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, τ an infinite place, $i, j \in I(\mathfrak{s})$, and $a, b \le \varrho$ frame indices.*

(a) *For $x \in G_S(\mathbb{A}_E)$: $\left(\mathrm{a}_S^\infty(x)_\tau\right)_{ij} = (x_{ij})_\tau \cdot \mathrm{sc}_{S,\tau}(j)/\mathrm{sc}_{S,\tau}(i)$. For $\gamma \in G_S(E)$: $\left(\mathrm{r}_S^\infty(\gamma)_\tau\right)_{ij} = (\gamma_{ij})_\tau \cdot \mathrm{sc}_{S,\tau}(j)/\mathrm{sc}_{S,\tau}(i)$ and $\mathrm{r}_S^f(\gamma) = \Lambda(S)^{-1}\,\gamma\,\Lambda(S)$, with γ read over $\mathbb{A}_{E,f}$.*

(b) *For $\gamma \in G_S(E)$: $Z(\mathrm{r}_S^\infty(\gamma)_\tau)_{ab} = \dfrac{\kappa_\tau(S)^{\varrho-a}\,\kappa_\tau(S)^{\varrho-b}}{N(S)} \cdot \left(Z_S(\gamma)_{ab}\right)_\tau$; and for a finite set m and a map e from m to the frame indices,*

$$\det\left(Z(\mathrm{r}_S^\infty(\gamma)_\tau)_{e(a'),e(b')}\right)_{a',b'\in m} = \prod_{a'\in m} \mathrm{fs}_S(\tau, e(a')) \cdot \left(\det\left(Z_S(\gamma)_{e(a'),e(b')}\right)_{a',b'\in m}\right)_\tau.$$

(c) *For $u \in G_S(\mathbb{A}_E)$: $\mathrm{sd}(\mathrm{a}_S^f(u)) = \mathrm{sd}(u)_f$, the finite part; for $u \in G_S(E)$: $\mathrm{sd}(\mathrm{r}_S^{\mathbb{A}}(u)) = \mathrm{sd}(u)$, embedded diagonally.*

Proof. (a) is the definition of a_S^∞ as conjugation by the diagonal matrix $\mathrm{Sc}_{S,\tau}$, and of lb_S. (b) By Lemma 3.1(c), $h_1(v, \mathrm{Sc}_{S,\tau}^{-1} w) = h_N(\mathrm{Sc}_{S,\tau} v, w)$ for the forms h_1, h_N of $T^{\mathrm{rat}}(\mathfrak{s}; 1)$ and $T_S^{\mathrm{rat}}(\mathbb{C})$. So the (a, b) entry is $h_N(\mathrm{Sc}_{S,\tau}\mathfrak{f}_a, \gamma\,\mathrm{Sc}_{S,\tau}\mathfrak{f}_b) = \mathrm{sc}_{S,\tau}(\mathfrak{f}_a)\,\mathrm{sc}_{S,\tau}(\mathfrak{f}_b)\,h_N(\mathfrak{f}_a, \gamma\mathfrak{f}_b)_\tau$, the scales being real, and Lemma 3.1(b) gives the factor. In a minor, the row and the column of index $e(a')$ each carry the factor $\kappa_\tau(S)^{\varrho-e(a')}/\sqrt{N(S)}$, whose square is $\mathrm{fs}_S(\tau, e(a'))$. (c) The entries of $\mathrm{sd}(\cdot)$ are at the positions $(\mathfrak{f}_a, \mathfrak{f}_{a+1})$; the matrix $\Lambda(S)$ is the identity on the e_a and its column z is z, so conjugation by it does not change these entries. □

Inputs (adeles). Let E be a CM field. (Ad1), unit 123: E, embedded diagonally, is a lattice of covolume one in $\mathbb{A}_E$; in particular a compact subset of $\mathbb{A}_E$ contains only finitely many elements of E. $\hat{O}_E$ is compact and open in $\mathbb{A}_{E,f}$ and stable under conjugation, and E is dense in $\mathbb{A}_{E,f}$. (Ad2), unit 122: the group of the invertible matrices over $\hat{O}_E$ is compact and open in the group of invertible matrices over $\mathbb{A}_{E,f}$. (Ad3), unit 114: a countable discrete subgroup Γ of a locally compact second countable group has a *cutoff*: a measurable function β with values in $[0,\infty]$ and $\sum_{\gamma\in\Gamma}\beta(\gamma y)=1$ for all y. (Ad4), unit 123: for $x\in\mathbb{A}_{E,f}$, $\psi_f(ux)=1$ for all $u\in\hat{O}_E$ if and only if $dx\in\hat{O}_E$ for every d in the different of E; and ψ_E is trivial on E.

Lemma 3.3 (discreteness and cutoffs)**.** *Let $S\in\mathrm{Fill}(E,\mathfrak{s})$ and $c\in\mathrm{Cl}(S)$.*

(a) *Let m be a finite set, ϕ a map from m to $I(\mathfrak{s})$, and C a compact set of families $(M_\tau)_\tau$ of complex $m\times m$ matrices indexed by the infinite places τ. Then only finitely many points of C are of the form $\left((\mathrm{r}_S^\infty(u)_\tau)_{\phi(i),\phi(j)}\right)_{\tau;\,i,j\in m}$ with $u\in\mathcal{U}_{S,c}$.*

(b) *Let K be a subgroup of $\mathcal{U}_{S,c}$ and $\Gamma=\mathrm{r}_S^\infty(K)\subseteq G_\infty(E,\mathfrak{s})$. Then Γ is discrete, and there is a measurable function $\beta\colon G_\infty(E,\mathfrak{s})\to[0,\infty]$ with $\sum_{u\in K}\beta(\mathrm{r}_S^\infty(u)y)=1$ for all y; it is a cutoff for Γ with the counting measure.*

Proof. (a) Let $u\in\mathcal{U}_{S,c}$ and $k=\mathrm{pos}_S(c,c;u)\in K_g(S)$, a matrix with entries in $\hat{O}_E$ together with its inverse. By Lemma 3.2(a), $u=(\Lambda(S)h_S(c))\,k\,(\Lambda(S)h_S(c))^{-1}$ over $\mathbb{A}_{E,f}$. So the finite adele of an entry $x=u_{\phi(i)\phi(j)}\in E$ lies in a compact set that does not depend on u, the image of the compact group of (Ad2) under a continuous map. If the point attached to u lies in C, then by Lemma 3.2(a) the archimedean components of x are those of a point of C times fixed scales, and lie in a compact set too. By (Ad1) only finitely many $x\in E$ are possible for each pair (i,j), and the point is determined by these entries. (b) The map $u\mapsto\mathrm{r}_S^\infty(u)$ is injective, the embeddings $E\to\mathbb{C}$ being injective. By (a) with ϕ the identity, every compact subset of $G_\infty(E,\mathfrak{s})$ contains only finitely many elements of Γ, so Γ is discrete. It is countable, and (Ad3) gives a cutoff β for Γ; the sum over K is the sum over Γ. □

LEAN `Filling.finite_classUnip_inter_compact` · `Filling.exists_cutoff_classUnip`

Lemma 3.4 (the groups $\mathcal{U}$ and $\mathcal{H}$ in the three systems of coordinates)**.** *Let $S\in\mathrm{Fill}(E,\mathfrak{s})$.*

(a) *For $x\in G_S(\mathbb{A}_{E,f})$: $\mathrm{lb}_S(x)\in\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ if and only if $x\in\mathcal{U}(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))$. For $\gamma\in G_S(E)$: $\mathrm{r}_S^f(\gamma)\in\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ if and only if $\gamma\in\mathcal{U}(T_S^{\mathrm{rat}}(E))$.*

(b) *For every $k\in G_f(E,\kappa)$, $\mathrm{inc}_S(k)\in\mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$; and the image of inc_S is $\mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$. For $\gamma_0\in\mathrm{U}_\kappa(E)$, $\mathrm{r}_S^f(\iota_{N(S)}(\gamma_0))=\mathrm{inc}_S(\gamma_0)$, where on the right γ_0 is read in $G_f(E,\kappa)$.*

(c) *For $c,c'\in\mathrm{Cl}(S)$ and $\gamma\in G_S(E)$: $\mathrm{pos}_S(c,c';\gamma)=\mathrm{B}_S(c)^{-1}\,\gamma\,\mathrm{B}_S(c')$ as matrices. For $c\in\mathrm{Cl}(S)$ and $\gamma\in G_S(E)$ with $\gamma\in\mathcal{U}(T_S^{\mathrm{rat}}(E))$: $\mathrm{pos}_S(c,c;\gamma)\in\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$.*

(d) *Let $c,c',c''\in\mathrm{Cl}(S)$, $s,t\in\mathsf{G}(S)$ and $\gamma,\delta\in G_S(E)$. If $\gamma\in\mathrm{Tm}_S(c,s,c')$ and $\delta\in\mathrm{Tm}_S(c',t,c'')$, then $\gamma\delta\in\mathrm{Tm}_S(c,st,c'')$. If $\gamma\in\mathrm{Tm}_S(c,s,c')$, then $\gamma^{-1}\in\mathrm{Tm}_S(c',s^{-1},c)$.*

Proof. (a) The matrix $\Lambda(S)$ and its inverse are block diagonal for the levels: they are the identity on the e_a and e_a^* and mix only the middle block, of level ϱ. By (G1), conjugation by them preserves unitriangularity for the levels, in both directions. The second claim follows, since an entry of γ is 0 or 1 in E exactly when it is so in $\mathbb{A}_{E,f}$. (b) $\iota_N(k)$ lies in $\mathcal{H}(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))$ by (G3), and conjugation by $\Lambda(S)$ keeps the columns of the e_a, e_a^* and z, since $\Lambda(S)$ fixes these vectors. Conversely let $h \in \mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$. Then $\Lambda(S)\, h\, \Lambda(S)^{-1} \in \mathcal{H}(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))$, and it is $\iota_N(k)$ for some k by (G3), N being a unit of $\mathbb{A}_{E,f}$ by (F2); so $h = \mathrm{inc}_S(k)$. The last formula is the definition. (c) By definition $h_S(c) = \Lambda(S)^{-1}\iota_N(\dot{c})\Lambda(S)$ and $\mathrm{r}_S^f(\gamma) = \Lambda(S)^{-1}\gamma\Lambda(S)$, which gives the formula. For the second claim, $\mathrm{r}_S^f(\gamma) \in \mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ by (a), and $h_S(c)^{-1}$ lies in $\mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})) \subseteq \mathcal{S}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, which normalizes $\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ by (G2). (d) Positions multiply, $\mathrm{pos}_S(c, c''; \gamma\delta) = \mathrm{pos}_S(c, c'; \gamma) \cdot \mathrm{pos}_S(c', c''; \delta)$, and $\mathrm{pos}_S(c', c; \gamma^{-1}) = \mathrm{pos}_S(c, c'; \gamma)^{-1}$; $K(S)$ is a group and red_S a homomorphism. □

Lemma 3.5 (the character)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$.*

(a) $|\psi_S(x)| = 1$ *for all* $x \in \mathbb{A}_{E,f}$*. For* $a \in \mathbb{A}_{E,f}$*:* $\psi_S(ra) = 1$ *for all* $r \in \hat{O}_E$ *if and only if* $a \in \hat{O}_E$*. In particular* $\psi_S(x) = 1$ *for every* $x \in \mathbb{A}_{E,f}$ *with* $x \in \hat{O}_E$*.*

(b) $\hat{g}(S)$ *has the value* $g(S)$ *in* $\mathbb{A}_{E,f}$ *and lies in* $\hat{O}_E$*; and* $\psi_S^{\mathcal{U}}(1) = 1$*.*

(c) *For* $r \in \hat{O}_E$*:* $\hat{g}(S)^{-1}r \in \hat{O}_E$ *if and only if* $\mathrm{red}_{S,x}(r) = 0$ *for all* $x = ((i, w), \epsilon)$ *as in Definition 2.25(ii).*

(d) *For every family* $(t_x)_x$ *of elements* $t_x \in \mathbb{F}_w$*, indexed by the* $x = ((i, w), \epsilon)$*, there is* $y \in \hat{O}_E$ *with* $\mathrm{red}_{S,x}(y) = t_x$ *for all* x*.*

Proof. (a) $\psi_S(ra) = \psi_f(r \cdot (-a/\varpi(S)))$. By (Ad4) this is 1 for all $r \in \hat{O}_E$ if and only if $-da/\varpi(S) \in \hat{O}_E$ for all d in the different, which is generated by $\varpi(S)$ (F6); that is, if and only if $a \in \hat{O}_E$. Take $a = 1$ for the last claim. (b) is clear; $\mathrm{sd}(1) = 0$. (c) is (F5), with the two reductions of r and of $\overline{r}$ written as the four maps $\mathrm{red}_{S,x}$. (d) Lift t_x to $\tilde{t}_x \in O_E$ and let $\varepsilon_w \in \hat{O}_E$ be the idempotent that is 1 at w and 0 at the other places. Put $y = \sum_x \tilde{t}_x \varepsilon_w$ over the x with ϵ false, plus $\sum_x \overline{\tilde{t}_x \varepsilon_w}$ over the x with ϵ true. Since $\overline{\varepsilon_w} = \varepsilon_{\overline{w}}$, the chosen places are distinct and no conjugate of a chosen place is chosen (F4), exactly one term survives each $\mathrm{red}_{S,x}$, and it gives t_x. □

Lemma 3.6 (reduction modulo a conjugate place)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$ and let F be a ring.*

(a) $J(T_S^{\mathrm{lat}}(F))$ *is a symmetric matrix. If F has an involution, then $T_S^{\mathrm{lat}}(F)$ is unimodular over every subring R of F; in particular $J(T_S^{\mathrm{lat}}(F))$ is hermitian and invertible.*

(b) *Let* $k \in K(S)$*,* $i \in \{0, 1\}$*,* $w \in \mathrm{Ch}_i(S)$ *and* ϵ *a truth value. Applying* $\mathrm{red}_{S,((i,w),\epsilon)}$ *to every entry of* k *gives the matrix* $\mathrm{adj}_S^{\epsilon}(\mathrm{red}_S(k)_{i,w})$*.*

Proof. (a) The matrix has the entries 0, ± 1, $-N(S)$ and is symmetric; the image of the natural number $N(S)$ lies in every subring and is fixed by every involution, so

Lemma 2.3(b) applies. (b) For ϵ false this is the definition of red_S. Let ϵ be true. The matrix k is an isometry of $J = J(T_S^{\mathrm{lat}}(\hat{O}_E))$ over $\hat{O}_E$, so $Jk^{-1} = k^* J$ by (G6), and $\overline{k} = (k^*)^{\mathrm{t}} = (Jk^{-1}J^{-1})^{\mathrm{t}} = J^{-1}\,(k^{-1})^{\mathrm{t}}\,J$, J being symmetric. Reducing modulo w gives the claim. □

LEAN `Filling.isUnimodular_latMiddle` · `Filling.transpose_splitGram` · `Filling.intGL_map_reduceAboveG`

Proof of Theorem E(a). Let $k \in K_g(S)$, that is $k \in K(S)$ with $\mathrm{red}_S(k) = 1$. By Lemma 3.6(b), for every $x = ((i,w),\epsilon)$ the map $\mathrm{red}_{S,x}$ sends k to $\mathrm{adj}_S^{\epsilon}(1) = 1$, so it kills every entry of $k-1$; by Lemma 3.5(c) the entries of $\hat{g}(S)^{-1}(k-1)$ lie in $\hat{O}_E$. Conversely, if $k \in G_S^{\mathrm{lat}}$ has entries in $\hat{O}_E$ with its inverse and $\hat{g}(S)^{-1}(k-1)$ is integral, then by Lemma 3.5(c) with ϵ false every entry of $k-1$ vanishes modulo every chosen place, so $\mathrm{red}_S(k) = 1$. □

LEAN `Filling.principalLevel_eq_unitaryLevel`

Proof of Theorem E(c). Put $\mathtt{z} = -(g\,\varpi(S))^{-1}\,\mathrm{sd}(x) \in \mathbb{A}_E$. By Lemma 3.2(c), $\psi_S^{\mathcal{U}}(\mathrm{a}_S^f(x)) = \psi_f(-\hat{g}(S)^{-1}\,\mathrm{sd}(x)_f/\varpi(S)) = \psi_f(\mathtt{z}_f)$. Let τ be an infinite place and $x'_\tau = \mathrm{a}_S^\infty(x)_\tau$. It lies in $\mathcal{U}(T^{\mathrm{rat}}(\mathfrak{s};1))$, a conjugate of a unitriangular matrix by a diagonal one (G1), and by Lemma 3.2(a) and Lemma 3.1,

$$\mathrm{sd}(x'_\tau) = \sum_{a<\varrho}(x_{\mathfrak{f}_a\mathfrak{f}_{a+1}})_\tau\,\frac{\mathrm{sc}_{S,\tau}(\mathfrak{f}_{a+1})}{\mathrm{sc}_{S,\tau}(\mathfrak{f}_a)} = \kappa_\tau(S)^{-1}\,\mathrm{sd}(x)_\tau = \frac{2\pi i}{g\,\varpi(S)_\tau}\,\mathrm{sd}(x)_\tau = -2\pi i\,\mathtt{z}_\tau.$$

Since $W_{S,\tau}^\sigma$ is a Bessel function, $W_{S,\tau}^\sigma(x'_\tau y_\tau) = \mathbf{e}(-2\pi i \mathtt{z}_\tau)\,W_{S,\tau}^\sigma(y_\tau)$ and $\mathbf{e}(-2\pi i\mathtt{z}_\tau) = e^{-2\pi i\cdot 2\,\mathrm{Re}\,\mathtt{z}_\tau}$. The product over τ of these factors is the archimedean part of $\psi_E(\mathtt{z})$, that is $\psi_E(\mathtt{z})/\psi_f(\mathtt{z}_f)$. □

LEAN `Filling.besselFn_adelicToInf_mul`

Corollary 3.7. *Let $S \in \mathrm{Fill}(E,\mathfrak{s})$, σ a side, $\gamma \in G_S(E)$ with $\gamma \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$, and $y \in G_\infty(E,\mathfrak{s})$. Then $W_S^\sigma(\mathrm{r}_S^\infty(\gamma)y)_\cdot = \psi_S^{\mathcal{U}}(\mathrm{r}_S^f(\gamma))^{-1}\,W_S^\sigma(y)_\cdot$.*

Proof. Theorem E(c) for $x = \mathrm{r}_S^{\mathbb{A}}(\gamma)$: here $\mathtt{z} \in E$, and ψ_E is trivial on E (Ad4). □

LEAN `Filling.besselFn_ratToInf_mul`

Lemma 3.8 (norms of kernels and amplitudes)**.** *Let $S \in \mathrm{Fill}(E,\mathfrak{s})$, σ a side, $\gamma \in G_S(E)$, $c,c' \in \mathrm{Cl}(S)$, $y \in G_\infty(E,\mathfrak{s})$ and $i \in \mathrm{Bc}(S)$. Then $y' \mapsto W_S^\sigma(y')_i$ and $y' \mapsto \mathcal{W}_S^\sigma(\gamma;y')$ are continuous,*

$$\|\mathcal{W}_S^\sigma(\gamma;y)\| = \prod_\tau \|W_{S,\tau}^\sigma(y_\tau)\| \cdot \prod_\tau \|W_{S,\tau}^\sigma((\mathrm{r}_S^\infty(\gamma)^{-1}y)_\tau)\|,$$

and $\|a_S^\sigma(c,c';\gamma)\| \le |a|_S^\sigma(c,c';\gamma)$.

Proof. The functions of a Bessel system are continuous. The squared norm of $\mathcal{W}_S^\sigma(\gamma;y)$ is $\sum_{i,i'}|W_S^\sigma(y)_i|^2|W_S^\sigma(\mathrm{r}_S^\infty(\gamma)^{-1}y)_{i'}|^2$, and a sum over tuples of a product is the product of the sums. The last inequality is the triangle inequality for the integral. □

LEAN `Filling.continuous_besselFn` · `Filling.continuous_besselKernel` · `Filling.enorm_besselKernel` · `Filling.enorm_amplitude_le`

The group $\mathcal{H}$ and the integral subgroup.

Lemma 3.9. *Let $S \in \mathrm{Fill}(E,\mathfrak{s})$ and write $\bar\pi = \bar\pi(S)$; for a unit p of $\mathbb{A}_{E,f}$ let D_p be the diagonal matrix indexed by κ with p at k_0 and 1 elsewhere.*

(a) *Let m be a finite set and l a matrix over $\mathbb{A}_{E,f}$ with rows indexed by κ and columns by m. If $D_{\bar\pi^{-1}}\, l$ is integral, then $\Lambda^\circ(\mathfrak{s};\bar\pi)\, l$ is integral. And $\Lambda^\circ(\mathfrak{s};\bar\pi)\, l$ is integral if and only if l is integral and its row k_0 has entries in $\bar\pi\hat{O}_E$.*

(b) *Let κ' be a finite set, p a unit of $\mathbb{A}_{E,f}$ such that at every finite place w either p is a unit at w or p is a unit at $\overline{w}$, $o \in \kappa'$, and $k \in G_f(E,\kappa')$ such that k and k^{-1} are integral and the row o of $k-1$ has entries in $p\hat{O}_E$. Then $D_{p^{-1}}\,(k-1)\,D_{\overline{p}^{-1}}$ is integral, with D now indexed by κ' and o in the place of k_0.*

(c) *Let $k \in G_f(E,\kappa)$ and let Π be a property of elements of $\mathbb{A}_{E,f}$ that holds for 0. Then all entries of $\mathrm{inc}_S(k)-1$ have Π if and only if all entries of $\Lambda^\circ(\mathfrak{s};\bar\pi)\,(k-1)\,D_{\overline{\bar\pi}^{-1}}$ have Π.*

Proof. (a) The rows of $\Lambda^\circ(\mathfrak{s};\bar\pi)\, l$ are the rows l_i for $i \neq k_0$, the row $\overline{\bar\pi}\, l_{k_0}$ and the row $-\bar\pi^{-1} l_{k_0}$. Both $\bar\pi$ and $\overline{\bar\pi}$ lie in $\hat{O}_E$ by (F2) and (Ad1), and $\overline{\bar\pi}\, l_{k_0} = N \cdot \bar\pi^{-1} l_{k_0}$; both claims follow. (b) The row o of $k-1$ lies in $p\hat{O}_E$. So does the row o of $k^{-1}-1 = -(k-1)\,k^{-1}$, because k^{-1} is integral. As $k^{-1} = k^*$, this row is the conjugate of the column o of $k-1$, which therefore lies in $\overline{p}\hat{O}_E$. The entries of the scaled matrix are $(k-1)_{ij}$, $p^{-1}(k-1)_{oj}$, $(k-1)_{io}\overline{p}^{-1}$ and $p^{-1}(k-1)_{oo}\overline{p}^{-1}$. At a place w where p is a unit, division by p is harmless and the column condition handles $\overline{p}$; at a place w where p is a unit at $\overline{w}$, $\overline{p}$ is a unit at w and the row condition handles p. (c) $\mathrm{inc}_S(k) - 1 = \Lambda(S)^{-1}(\iota_N(k)-1)\Lambda(S)$. The matrix $\iota_N(k)-1$ is zero outside the block of κ, where it is $k-1$; the columns of $\Lambda(S)^{-1}$ at κ form the matrix $\Lambda^\circ(\mathfrak{s};\bar\pi)$ in the middle rows, and the rows of $\Lambda(S)$ at κ form $D_{\overline{\bar\pi}^{-1}}$ in the columns of κ and vanish elsewhere. So the entries of $\mathrm{inc}_S(k)-1$ are those of the product and zeros. □

LEAN `Filling.isIntMatrix_middleBaseChange_mul` · `Filling.isIntMatrix_scaleAt_sub_one` · `Filling.forall_inclHFin_sub_one_iff`

Proof of Theorem E(b). An isometry x of the unimodular matrix $J = J(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ lies in $K(S)$ if and only if $x-1$ is integral, since then $x^{-1} = J^{-1}x^*J$ is integral too (Lemma 3.6(a)). By Lemma 3.9(c), with Π integrality, $\mathrm{inc}_S(k) \in K(S)$ if and only if $M = \Lambda^\circ(\mathfrak{s};\bar\pi)\,(k-1)\,D_{\overline{\bar\pi}^{-1}}$ is integral. If M is integral, so is $M\,D_{\overline{\bar\pi}} = \Lambda^\circ(\mathfrak{s};\bar\pi)(k-1)$, and Lemma 3.9(a) shows that $k-1$ is integral with row k_0 in $\bar\pi\hat{O}_E$; then k is integral, and so is $k^{-1} = k^*$. Conversely, if k satisfies these conditions, Lemma 3.9(b) with $p = \bar\pi$ and $o = k_0$, whose hypothesis is (F2), shows that $D_{\bar\pi^{-1}}(k-1)D_{\overline{\bar\pi}^{-1}}$ is integral, and Lemma 3.9(a) with $l = (k-1)D_{\overline{\bar\pi}^{-1}}$ that M is. □

LEAN `Filling.inclHFin_mem_latStabilizer`

Lemma 3.10. *Let $S \in \mathrm{Fill}(E,\mathfrak{s})$.*

(a) *Let $k \in G_f(E,\kappa)$ with $\mathrm{inc}_S(k) \in K(S)$, $i \in \{0,1\}$ and $w \in \mathrm{Ch}_i(S)$. Then $\mathrm{red}_S(\mathrm{inc}_S(k))_{i,w} = 1$ if and only if k, which is integral by Theorem E(b), reduces to 1 modulo w.*

(b) *For every real function ϕ on $G_f(E,\kappa)$, the class sum $\sum_c \phi(\dot c)/\#(\Gamma_f(E,\kappa) \cap \dot c\, K^{\mathrm{col}}(S)\, \dot c^{-1})$ over $c \in \mathrm{Cl}(S)$ equals $\sum_{c\in\mathrm{Cl}(S)} \phi(\dot c)$.*

(c) *For $i \in \{0,1\}$ and $w \in \mathrm{Ch}_i(S)$, the residue field $\mathbb{F}_w$ has $q_i(S)$ elements.*

Proof. (a) Both conditions say that every entry of the matrix minus 1 lies in the maximal ideal at w. By Lemma 3.9(c) with this property, the condition for $\mathrm{inc}_S(k)$ is the condition for $\Lambda^\circ(\mathfrak{s};\bar\pi)(k-1)D_{\overline{\bar\pi}^{-1}}$. A chosen place has $q_w = q_i(S) \neq N$ by (F3) and (F4), so $\bar\pi$ is a unit at w by (F2), and so is $\overline{\bar\pi}$, as $\bar\pi\overline{\bar\pi} = N$ is a unit at w. Multiplying rows and columns by units at w does not change the condition, and the row z of $\Lambda^\circ(\mathfrak{s};\bar\pi)(k-1)$ is a unit multiple of the row k_0 of $k-1$. (b) The stabilizers are trivial by (F1). (c) is (F4). □

4 Links and normal forms

In this section F is a ring with involution, $\mathfrak{s}$ a shape and T an $\mathfrak{s}$-form over F; vectors of $F^{I(\mathfrak{s})}$ are written (a,p,a') with e-coordinates a, middle part p and e^*-coordinates a'. By the shape of $J(T)$, $J(T)\,(a,p,a') = (a', Tp, a)$; hence a vector is orthogonal to $X = \mathrm{span}(e_0,\dots,e_{\varrho-1})$ if and only if its e^*-part vanishes, and $[\mathfrak{e} \mid \gamma\mathfrak{e}]^* J(T)\,t = 0$ if and only if the e^*-parts of t and of $\gamma^{-1}t$ vanish; and $\mathrm{L}(\gamma)t = (t_{\mathrm{mid}}, (\gamma^{-1}t)_{\mathrm{mid}})$.

LEAN `splitGram_mulVec` · `isotropicFramePair_mulVec_eq_zero_iff` · `linkMatrix_mulVec`

Lemma 4.1 (the link in coordinates)**.** *Let F be a ring with involution, $\mathfrak{s}$ a shape, T an $\mathfrak{s}$-form over F, $\gamma \in G(T)$ and $p = (p_1,p_2) \in F^{M(\mathfrak{s})} \times F^{M(\mathfrak{s})}$. Then $p \in \mathrm{link}(\gamma)$ if and only if there is $a \in F^\varrho$ such that $\gamma\,(a,p_2,0)$ has middle part p_1 and vanishing e^*-part.*

Proof. Every t is γw for a unique w. The conditions on t in Definition 2.5 say that γw and w have vanishing e^*-parts, and then $\mathrm{L}(\gamma)t = ((\gamma w)_{\mathrm{mid}}, w_{\mathrm{mid}})$. □

LEAN `mem_link`

Proof of Theorem B(a). Let $u,w \in \mathcal{U}(T)$. We show $\mathrm{link}(\gamma) \subseteq \mathrm{link}(u\gamma w^{-1})$. Let $t \perp X + \gamma X$. By (G5), u and w preserve X, hence $X^\perp$, and act trivially on $X^\perp/X$. So $ut \perp X$, $(u\gamma w^{-1})^{-1}(ut) = w\gamma^{-1}t \perp X$, and the middle parts of ut and of $w\gamma^{-1}t$ are those of t and of $\gamma^{-1}t$. Thus $\mathrm{L}(\gamma)t \in \mathrm{link}(u\gamma w^{-1})$. Applying the inclusion to $(u^{-1}, u'^{-1}, \gamma)$ and to $(u, u', u^{-1}\gamma u')$ gives the two inclusions of the theorem. □

LEAN `Filling.link_besselU_mul`

Lemma 4.2 (normal forms)**.** *Let F be a ring with involution, $\mathfrak{s}$ a shape, T an $\mathfrak{s}$-form over F, $\gamma, u, u' \in G(T)$, and j a natural number.*

(a) *If $\gamma \in \mathrm{NF}_j$, then $\gamma^{-1} \in \mathrm{NF}_j$.*

(b) *If $u \in \mathcal{U}(T)$ and $\gamma \in \mathrm{NF}_j$, then $u\gamma \in \mathrm{NF}_j$.*

(c) *Let $j \le \varrho + 1$ and suppose $\gamma \in \mathrm{NF}_j$. Then for every $y \in F^{\varrho+1}$ there are $x, y' \in F^{\varrho+1}$ with $y'_a = y_a$ for all frame indices $a \ge j$ and $\mathfrak{f}x = (\gamma\mathfrak{f})y'$.*

(d) *If $u \in \mathcal{U}(T)$ and $u' \in \mathcal{U}(T)$, then for every $N \in F$, $\mathfrak{g}(N; Z_T(u^{-1}\gamma u')) = \mathfrak{g}(N; Z_T(\gamma))$.*

Proof. (a) Let c with $c\bar c = 1$ be as in Definition 2.26, and for $a \ge j$ let x, y be the vectors with $\mathfrak{f}x = (\gamma\mathfrak{f})y$, $x_a = c$, $y_a = 1$. Then $\mathfrak{f}(\bar c y) = (\gamma^{-1}\mathfrak{f})(\bar c x)$, the coefficients at a are $\bar c$ and $\bar c c = 1$, and those above a vanish; so $\bar c$ serves for γ^{-1}. (b) Keep c and y, and replace x by the vector x' with $\mathfrak{f}x' = u\,\mathfrak{f}x$. By (G5), $u\mathfrak{f}_b - \mathfrak{f}_b \in \mathrm{span}(\mathfrak{f}_{b'} : b' < b)$, so $x'_a = x_a$ and $x'_b = 0$ for $b > a$; and $\mathfrak{f}x' = u(\gamma\mathfrak{f})y = ((u\gamma)\mathfrak{f})y$. (c) Downward

induction on j. For $j = \varrho + 1$ take $x = y' = 0$. Let $j \le \varrho$ and let x, y'' solve the problem for $j+1$, which is possible because normal form from j implies normal form from $j+1$. With X_j, Y_j the vectors of Definition 2.26 for $a = j$, so that $(Y_j)_j = 1$ and both vanish above j, put $x' = x + (y_j - y''_j)X_j$ and $y' = y'' + (y_j - y''_j)Y_j$. (d) By (G4) the determinant of $Z_T(\gamma)$, which is its leading minor of order $\varrho + 1$, and its leading minor of order ϱ do not change. □

LEAN `IsNormalForm.inv` · `IsNormalForm.besselU_mul` · `Filling.exists_frameImage_eq_of_isNormalForm` · `Filling.frameDisc_frameGram_besselU_mul`

Corollary 4.3. *Let E be a CM field with a CM type, $\mathfrak{s}$ a shape, $S \in \mathrm{Fill}(E, \mathfrak{s})$ and $j \in \{0, \dots, \varrho + 1\}$. The set of the $\gamma \in G_S(E)$ with $\gamma \in \mathrm{Lv}_j(S)$ is stable: $\{\gamma : \gamma \in \mathrm{Lv}_j(S)\} \in \mathrm{Stab}(S)$.*

Proof. Let $u, u' \in \mathcal{U}(T_S^{\mathrm{rat}}(E))$. From $\gamma \in \mathrm{NF}_j$ one gets normal form from j of $u^{-1}\gamma$, of $\gamma^{-1}u$, of $u'^{-1}\gamma^{-1}u$ and of $u^{-1}\gamma u'$, by Lemma 4.2(b), (a), (b), (a); the converse is the same with u^{-1}, u'^{-1}. The minor $\mathrm{D}_j(Z_S(\gamma))$ and $\mathfrak{g}_S(\gamma)$ are unchanged by (G4) and Lemma 4.2(d). □

LEAN `Filling.isStable_hasLevel`

> **Input (L1)**, unit 112. Let P, P' be matrices over a field with the same finite index sets, s, s' sets of column indices, and x^0, y^0 column vectors. If every row vector l with $(lP)_b = 0$ for $b \in s$ and $(lP')_b = 0$ for $b \in s'$ satisfies $lPx^0 = lP'y^0$, then there are x, y with $Px = P'y$, $x_b = x^0_b$ for $b \notin s$ and $y_b = y^0_b$ for $b \notin s'$.

Proof of Theorem B(b). Write $T = T_S^{\mathrm{rat}}(E)$, $h = h_T$, and $p = (p_1, p_2)$. For vectors s, t with vanishing e^*-parts, $h(s,t) = s^*_{\mathrm{mid}}\, T\, t_{\mathrm{mid}}$. Let $p = \mathrm{L}(\gamma)t$ and $q = \mathrm{L}(\gamma)s$ be in the link. Then by (G6)

$$q^*\, Q_S^{\pm}\, p = h(s,t) - h(\gamma^{-1}s, \gamma^{-1}t) = 0.$$

Conversely let p be orthogonal to the link. By Lemma 4.1 we need $x = (a', p_1, 0)$ and $y = (a, p_2, 0)$ with $x = \gamma y$. Apply (L1) to $P = 1$, $P' = \gamma$, the sets $s = s'$ of the indices of the e_a, and $x^0 = (0, p_1, 0)$, $y^0 = (0, p_2, 0)$. A row vector l is $h(t, \cdot)$ for a vector t, since J_S is hermitian and invertible. The conditions on l say $h(t, e_a) = 0$ and $h(t, \gamma e_a) = 0$ for all a, that is, $t \perp X + \gamma X$; then $q = \mathrm{L}(\gamma)t$ lies in the link, and

$$lx^0 - l\gamma y^0 = h(t, x^0) - h(\gamma^{-1}t, y^0) = t^*_{\mathrm{mid}} T p_1 - (\gamma^{-1}t)^*_{\mathrm{mid}} T p_2 = q^*\, Q_S^{\pm}\, p = 0.$$

So (L1) applies. □

LEAN `mem_link_iff_orthogonal`

> **Input (L2)**, unit 119. Let A be a field with involution, T an $\mathfrak{s}$-form over A, p a sequence of units of A and $\sigma_0 \in \mathcal{H}_\varrho(T)$. The matrix of $w_\varrho(p)\,\sigma_0$ maps $(a, m, a') \mapsto ((\overline{p_b}^{-1} a'_b)_b,\ \sigma_0^{\mathrm{mid}} m,\ (p_b a_b)_b)$, where σ_0^{mid} is the middle block of σ_0; and $Z_T(w_\varrho(p)\,\sigma_0)$ is the diagonal matrix with the entries $p_0, \dots, p_{\varrho-1}$ and $Z_T(\sigma_0)_{\varrho\varrho} = h_T(z, \sigma_0 z)$.

Proposition 4.4 (the big cell)**.** *Let A be a field with involution, $\mathfrak{s}$ a shape, T an $\mathfrak{s}$-form over A, p, q sequences of units of A and $\sigma_0, \sigma_1 \in G(T)$ with $\sigma_0 \in \mathcal{H}_\varrho(T)$ and $\sigma_1 \in \mathcal{H}_\varrho(T)$.*

(a) *For $N \in A$, with $t = Z_T(\sigma_0)_{\varrho\varrho}$ and $d = \prod_{a<\varrho} p_a$:* $\mathsf{g}(N; Z_T(w_\varrho(p)\,\sigma_0)) = d\,\overline{d}\,(t\,\overline{t} - N^2)$.

(b) $\mathrm{link}(w_\varrho(p)\,\sigma_0) = \mathrm{link}(w_\varrho(q)\,\sigma_1)$ *if and only if* $\sigma_0 = \sigma_1$.

Proof. (a) By (L2) the frame Gram matrix is diagonal with determinant dt and leading minor d of order ϱ. (b) By Lemma 4.1 and (L2), $(p_1, p_2) \in \mathrm{link}(w_\varrho(p)\sigma_0)$ if and only if there is a such that $w_\varrho(p)\sigma_0(a, p_2, 0) = (0, \sigma_0^{\mathrm{mid}} p_2, (p_b a_b)_b)$ has middle part p_1 and no e^*-part: this forces $a = 0$ and $p_1 = \sigma_0^{\mathrm{mid}} p_2$. So the link is the graph of the middle block of σ_0, whatever p is, and two elements of $\mathcal{H}_\varrho(T)$ with the same middle block are equal. □

LEAN `Filling.frameDisc_weylElem_mul` · `Filling.link_big_cell_eq_iff`

5 Lattices in subspaces and Siegel's lemma

Lemma 5.1 (a basis adapted to a kernel)**.** *Let K_0 be a field, P and Ω finite sets, A an $\Omega \times P$ matrix and x a $P \times \Omega$ matrix over K_0 with $\det(Ax) \neq 0$, and $L \subseteq K_0^P$ a subspace that contains the columns of x. Then there are a natural number s and a matrix y with s columns such that: $s = \dim(L \cap \ker A)$; $(x \mid y)$ has a left inverse; the columns of $(x \mid y)$ span L; the columns of y lie in L; $Ay = 0$; and if yt lies in the span of the columns of x for a vector t, then $t = 0$.*

Proof. Let y be a matrix whose columns are a basis of $L \cap \ker A$, with a left inverse l, and put $C = (Ax)^{-1}A$. Then $Cx = 1$ and $Cy = 0$, since $Ay = 0$. The matrix with the rows C and $l - lxC$ is a left inverse of $(x \mid y)$. Every $v \in L$ is $x(Cv) + (v - xCv)$ with $v - xCv \in L \cap \ker A$. If $yt = xw$, then $w = Cxw = Cyt = 0$, so $yt = 0$ and $t = l(yt) = 0$. □

LEAN `Filling.exists_basis_extend_ker` · `Filling.mul_eq_zero_of_range_le_ker`

Inputs (lattices). Let E be a stably unramified CM field. (La1), unit 120: every subspace of K_0^P, K_0 a field, is the column space of a matrix with a left inverse. (La2), unit 57: for a matrix M over $\mathbb{A}_{E,f}$ with a left inverse there is an invertible matrix a over $\mathbb{A}_{E,f}$ such that Ma is primitive over $\hat{O}_E$ and the columns of a span the lattice of the v with Mv integral. With (La1) this gives the matrix $\mathrm{m}_H(V)$ of Definition 2.28: take a matrix y over E with a left inverse l whose columns span V, and apply (La2) to $M = H(y)_{\mathbb{A}_f}$, which has the left inverse $(l)_{\mathbb{A}_f} L$. (La3), unit 57: $[\det(J^*MJ)] = [\det M]\,[\det J]^2$ for square matrices over $\mathbb{A}_{E,f}$; for an integral invertible matrix M, the index of its column lattice in $\hat{O}_E^s$ is $[\det M]$; indices of lattices are multiplicative in towers, and the index of the images of two lattices under a linear map divides their index; and (units 57 and 123) $[x] = |N_{E/\mathbb{Q}}(x)| = \prod_\tau |x_\tau|^2$ for $x \in E^\times$. (La4), unit 57, *Jacobi's identity for complements*: let J be a hermitian matrix that is unimodular over $\hat{O}_E$, F an integral matrix and n a primitive matrix with $F^*J\mathsf{n} = 0$ whose numbers of columns add up to the size of J, and suppose F has a left inverse. Then $[\det(\mathsf{n}^*J\mathsf{n})] \cdot i^2 = [\det(F^*JF)]$, where i is the index of $\hat{O}_E^s \cap \{v : Fv \text{ integral}\}$ in $\{v : Fv \text{ integral}\}$.

Proposition 5.2 (discriminants and indices)**.** *Let E be a stably unramified CM field, P, Ω, Ω' finite sets, H a $P \times \Omega$ matrix over $\mathbb{A}_{E,f}$ with a left inverse L, $LH = 1$,*

$V \subseteq E^{\Omega}$ a subspace, s a natural number with $s = \dim_E V$, x an $\Omega \times s$ matrix over E whose columns lie in V, w an invertible $s \times s$ matrix over $\mathbb{A}_{E,f}$, and D a real number with

$$[\det(x^* x)_{\mathbb{A}_f}] \cdot [\det w]^2 = D \qquad \text{and} \qquad D \neq 0.$$

Let Y be an $\Omega' \times P$ matrix over $\mathbb{A}_{E,f}$ and K an $\hat{O}_E$-submodule of $\mathbb{A}_{E,f}^{\Omega'}$. Put $\mathsf{n} = H(x)_{\mathbb{A}_f} w$. If n is integral and every column of $Y\mathsf{n}$ lies in K, then, with i the index of $K \cap \Lambda$ in the column lattice Λ of $YH\,\mathrm{m}_H(V)$,

$$\left(\mathrm{disc}_H(V) \cdot i\right)^2 \leq D, \qquad \mathrm{disc}_H(V) > 0, \qquad i \geq 1.$$

Proof. Let $\mathrm{m} = \mathrm{m}_H(V) = (y)_{\mathbb{A}_f} a$ with y, a as in Definition 2.28, and let l be an integral left inverse of $H\mathrm{m}$. The columns of x lie in V, the column space of y, so $x = yB$ for a matrix B over E, and $(x)_{\mathbb{A}_f} w = \mathrm{m}\, A$ with $A = a^{-1}(B)_{\mathbb{A}_f} w$. By (La3),

$$D = [\det(w^* (x^* x)_{\mathbb{A}_f} w)] = [\det(A^* \mathrm{m}^* \mathrm{m}\, A)] = \mathrm{disc}_H(V)^2 \cdot [\det A]^2.$$

As $D \neq 0$, $[\det A] \neq 0$ and $\mathrm{disc}_H(V) \neq 0$, so A is invertible and $\mathrm{disc}_H(V) > 0$. Moreover $A = l(H\mathrm{m}A) = l\,\mathsf{n}$ is integral, so by (La3) $[\det A]$ is the index of the column lattice of A in $\hat{O}_E^s$. The map $v \mapsto YH\mathrm{m}v$ carries $\hat{O}_E^s$ onto Λ and the column lattice of A into $K \cap \Lambda$, the columns of $Y\mathsf{n} = YH\mathrm{m}A$ lying in K. Hence i divides the index of the image of the column lattice of A in Λ, which divides $[\det A]$; so $1 \leq i \leq [\det A]$ and $(\mathrm{disc}_H(V)\, i)^2 \leq D$. □

LEAN `Filling.sublatticeDisc_mul_index_sq_le`

Inputs (geometry of numbers). Let E be a CM field with $f = f(E)$. (M1), unit 121, *Minkowski's second theorem in adelic form*: let s be a natural number, r_τ an invertible complex $s \times s$ matrix for each infinite place τ and a an invertible $s \times s$ matrix over $\mathbb{A}_{E,f}$. Then there are a basis $B_1, \dots, B_s$ of E^s and integers $z_1, \dots, z_s$ such that $a^{-1}B_j \in \hat{O}_E^s$, $\sum_\tau \|r_\tau^{-1}(B_j)_\tau\|^2 \leq 4^{z_j}$ for all j, and $\prod_\tau |\det r_\tau|^2 \cdot [\det a]^{-1} \cdot 4^{f\sum_j z_j} \leq (8fs\ \mathrm{rd}_E)^{fs}$. The second reader of this write-up compared it with Bombieri and Vaaler [1], Theorem 3, of which it is a weaker form. (M2), unit 120, Gram–Schmidt: a complex matrix X with a left inverse has Xr with orthonormal columns for some invertible r. (M3), unit 121: for $u \in G_f(E, \kappa)$, every non-zero $x \in E^\kappa \cap u\hat{O}_E^\kappa$ has $\|x\| \geq 1$. (M4), unit 114: if points of a real normed space of dimension d have norms and mutual distances at least 1, then for every integer $\nu \geq d + 2$ the sum of their norms to the power $-\nu$ is at most 5^ν.

Proof of Theorem C(a). Let $\mathrm{m} = \mathrm{m}_{u^{-1}}(V) = (x)_{\mathbb{A}_f} b$, with x a matrix over E with a left inverse l_0 whose columns span V, and b invertible over $\mathbb{A}_{E,f}$. The orthogonal complement $V^\perp = \ker x^*$ has dimension s, because x^* is surjective, with right inverse l_0^*. Let $\mathrm{m}' = \mathrm{m}_{u^{-1}}(V^\perp) = (y)_{\mathbb{A}_f} a$, with y a matrix over E with a left inverse l whose columns span $V^\perp$, and a invertible. Then $y^* x = 0$, and since $\ker x^*$ lies in the column space of y there are matrices f_0, t_0 with $yf_0 + t_0 x^* = 1$; hence a vector v with $y^* v = 0$ is $v = x(t_0^* v) \in V$, and $V = \ker y^*$.

The two discriminants agree. Apply (La4) with $J = 1$, $F = u^{-1}\mathrm{m}$ and $\mathsf{n} = u^{-1}\mathrm{m}'$: both are primitive, their numbers of columns add up to $\#\kappa$, and $F^*\mathsf{n} = \mathrm{m}^*\mathrm{m}' = b^* (x^* y)_{\mathbb{A}_f} a = 0$ because u is unitary. Since F is primitive, Fv is integral only for integral v, so the index in (La4) is 1 and

$$\mathrm{disc}_{u^{-1}}(V^\perp)^2 = [\det(\mathrm{m}'^* \mathrm{m}')] = [\det(\mathrm{m}^* \mathrm{m})] = \mathrm{disc}_{u^{-1}}(V)^2. \tag{1}$$

Short vectors in $V^\perp$. By (M2) choose for each τ an invertible r_τ such that $y_\tau r_\tau$ has orthonormal columns; then $|\det r_\tau|^{-2} = \det(y^*y)_\tau$. Apply (M1) to $(r_\tau)_\tau$ and a, and put $X_j = yB_j$. These vectors span $V^\perp$, so $V = \ker y^*$ is the set of the v with $X_j^* v = 0$ for all j. They are non-zero, as y has a left inverse, and $u^{-1}X_j = (u^{-1}\mathrm{m}')(a^{-1}B_j)$ is integral. Since $y_\tau r_\tau$ is an isometry,

$$\|X_j\|^2 = \sum_\tau \|y_\tau r_\tau \cdot r_\tau^{-1}(B_j)_\tau\|^2 = \sum_\tau \|r_\tau^{-1}(B_j)_\tau\|^2 \le 4^{z_j}.$$

Finally, by (La3) and (1),

$$\mathrm{disc}_{u^{-1}}(V)^2 = [\det(a^*\,(y^*y)_{\mathbb{A}_f}\,a)] = \prod_\tau |\det(y^*y)_\tau|^2 \cdot [\det a]^2 = \Big(\prod_\tau |\det r_\tau|^{-2}\,[\det a]\Big)^2.$$

So

$$\Big(\prod_j \|X_j\|\Big)^{2f} \le 4^{f\sum_j z_j} \le (8fs\ \mathrm{rd}_E)^{fs} \prod_\tau |\det r_\tau|^{-2}[\det a] = (8fs\ \mathrm{rd}_E)^{fs}\ \mathrm{disc}_{u^{-1}}(V).$$

□

LEAN `Filling.siegel_lemma`

Proof of Theorem C(b). Write $k = \#\kappa$ and $\Lambda_u = E^\kappa \cap u\hat{O}_E^\kappa$. If $s > k$, no subspace V has $\dim V + s = k$, the sum is empty, and the bound holds because its right side is at least 1. Let $s \le k$. For each V with $\dim V + s = k$ choose $X(V) = (X_1, \dots, X_s)$ as in (a). The subspace V is determined by $X(V)$, and $\prod_j \|X_j\| \ge 1$ by (M3). Raising the bound of (a) to the power $k+1$ and using $(8fs\ \mathrm{rd}_E)^{fs(k+1)} \le (8fk\ \mathrm{rd}_E)^{f(k+1)s}$, which holds as $s \le k$,

$$\mathrm{disc}_{u^{-1}}(V)^{-(k+1)} \le (8fk\ \mathrm{rd}_E)^{f(k+1)s} \prod_{j=1}^{s} \|X_j\|^{-2f(k+1)}.$$

Summing over V, and then over all s-tuples of non-zero vectors of Λ_u, the right side is at most $(8fk\ \mathrm{rd}_E)^{f(k+1)s}\big(\sum_x \|x\|^{-2f(k+1)}\big)^s$, the sum over the non-zero $x \in \Lambda_u$. These points of the real vector space $\mathbb{C}^{f\kappa}$ of dimension $2fk$ have norms and mutual distances at least 1 by (M3), and $2f(k+1) \ge 2fk+2$; by (M4) the inner sum is at most $5^{2f(k+1)} = 25^{f(k+1)}$. As $25 \cdot 8 = 200$, the claim follows. □

LEAN `Filling.tsum_sublatticeDisc_inv_le`

6 Strong approximation and terms in the Bessel subgroup

Inputs (the unipotent group, floor by floor). Let A be a ring with involution with an element t, $t+\overline{t}=1$, and T an $\mathfrak{s}$-form over A with $J(T)$ hermitian and invertible. For $l<\varrho$ and a pair (v,β) of a vector $v\in A^{I(\mathfrak{s})}$ and an element $\beta\in A$ with $\overline{\beta}=-\beta$, the *Heisenberg element* $\nu_l(v,\beta)\in G(T)$ is an Eichler map along e_l whose entries are polynomials in the coordinates of v, their conjugates, β and t. (U1), unit 119: $\nu_l(v,\beta)\in\mathcal{U}(T)$, and $\mathcal{U}(T)$ is generated by these elements: if a subset of $G(T)$ contains 1 and is stable under left multiplication by all $\nu_l(v,\beta)$, $l<\varrho$, then it contains $\mathcal{U}(T)$. (U2), unit 29: if $J(T)$ is invertible over a Hausdorff topological ring with continuous involution, the topology of $G(T)$ is induced by the entries. (U3), unit 1: for a subring $Q\subseteq A$, a unit g of A, and $k\in G(T)$ with entries in Q together with its inverse and $g^{-1}(k-1)$ with entries in Q: $g^{-1}\operatorname{sd}(k)\in Q$; and if $k=uh$ with $u\in\mathcal{U}(T)$ and $h\in\mathcal{H}(T)$, then h has the same two properties. (U4), unit 112: let $\Gamma\to G$ be a homomorphism, $K\subseteq G$ a subgroup and $(r_c)_c$ representatives of the double cosets $\Gamma\backslash G/K$. Every $g\in G$ is $\gamma r_c k$ with $\gamma\in\Gamma$, a class c and $k\in K$. If $r_d^{-1}\gamma r_d\in K$ only for $\gamma=1$, then $r_c^{-1}\gamma r_d\in K$ implies $c=d$ and $\gamma=1$.

Proof of Theorem A(a). $J(T')$ is hermitian and invertible, as the image of $J(T)$. Let $\mathcal{C}$ be the closure in $G(T')$ of the image of $\mathcal{U}(T)$; it is a subgroup. By (U1) for T', with $t=\frac{1}{2}$, it suffices to show $\nu_l(v,\beta)\in\mathcal{C}$ for all $l<\varrho$, all v over $\mathbb{A}_{E,f}$ and all skew $\beta\in\mathbb{A}_{E,f}$. A skew β is $\beta'-\overline{\beta'}$ with $\beta'=\frac{1}{2}\beta$. The map $(v,\beta')\mapsto\nu_l(v,\beta'-\overline{\beta'})$ is continuous by (U2), its entries being polynomials. The pairs with entries in E are dense by (Ad1), and for such a pair $\nu_l(v,\beta'-\overline{\beta'})$ is the image of the Heisenberg element over E (an identity of matrices that the formal text checks entry by entry), which lies in $\mathcal{U}(T)$ by (U1). Hence all $\nu_l(v,\beta)$ lie in $\mathcal{C}$. □

LEAN `besselU_dense`

Proof of Theorem A(b). By Theorem E(a) and (Ad1), (Ad2), $K_g(S)$ is open in G_S^{lat}: integrality of a matrix and of $\hat{g}(S)^{-1}(k-1)$ are open conditions. The map $\zeta\mapsto y^{-1}x^{-1}\operatorname{lb}_S(\zeta)\,y$ from $G_S(\mathbb{A}_{E,f})$ to G_S^{lat} is continuous, so the preimage of $K_g(S)$ is open; it contains $\zeta_0=\operatorname{lb}_S^{-1}(x)$, which lies in $\mathcal{U}(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))$ by Lemma 3.4(a). By Theorem A(a) for $T=T_S^{\mathrm{rat}}(E)$ and $T'=T_S^{\mathrm{rat}}(\mathbb{A}_{E,f})$, the point ζ_0 is a limit of images of elements of $\mathcal{U}(T_S^{\mathrm{rat}}(E))$; one of them, u, has its image in the open set, and lb_S of this image is $\mathrm{r}_S^f(u)$. □

LEAN `Filling.exists_besselU_approx`

Lemma 6.1 (characters and the principal level)**.** *Let $S\in\operatorname{Fill}(E,\mathfrak{s})$.*

(a) *Let $u,v\in G_S^{\mathrm{lat}}$ with $u\in\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and $v\in\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, and $g_0\in G_f(E,\kappa)$ with $u^{-1}(\operatorname{inc}_S(g_0)^{-1}\,v\operatorname{inc}_S(g_0))\in K_g(S)$. Then $\psi_S^{\mathcal{U}}(v)=\psi_S^{\mathcal{U}}(u)$.*

(b) *Let $c\in\operatorname{Cl}(S)$ and $u\in G_S^{\mathrm{lat}}$ with $u\in\mathcal{U}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$. Then there is $u_0\in\mathcal{U}(T_S^{\mathrm{rat}}(E))$ with $u^{-1}\operatorname{pos}_S(c,c;u_0)\in K_g(S)$ and $\psi_S^{\mathcal{U}}(\mathrm{r}_S^f(u_0))=\psi_S^{\mathcal{U}}(u)$.*

Proof. (a) Put $h=\operatorname{inc}_S(g_0)\in\mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and $k=u^{-1}h^{-1}vh\in K_g(S)$. By Theorem E(a) and (U3), $\hat{g}(S)^{-1}\operatorname{sd}(k)\in\hat{O}_E$, so $\psi_S(\hat{g}(S)^{-1}\operatorname{sd}(k))=1$ by Lemma 3.5(a). All elements involved lie in $\mathcal{S}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, where $\operatorname{sd}(\cdot)$ is additive and vanishes on $\mathcal{H}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ by (G2). Hence $\operatorname{sd}(v)=\operatorname{sd}(h^{-1}vh)=\operatorname{sd}(uk)=\operatorname{sd}(u)+\operatorname{sd}(k)$

and $\psi^{\mathcal{U}}_S(v) = \psi_S(\hat{g}(S)^{-1}\,\mathrm{sd}(u))\,\psi_S(\hat{g}(S)^{-1}\,\mathrm{sd}(k)) = \psi^{\mathcal{U}}_S(u)$. (b) The element $x = h_S(c)\,u\,h_S(c)^{-1}$ lies in $\mathcal{U}(T^{\mathrm{lat}}_S(\mathbb{A}_{E,f}))$ by (G2). Theorem A(b), with $y = h_S(c)$, gives $u_0 \in \mathcal{U}(T^{\mathrm{rat}}_S(E))$ with $h_S(c)^{-1}x^{-1}\mathrm{r}^f_S(u_0)h_S(c) = u^{-1}\mathrm{pos}_S(c,c;u_0) \in K_g(S)$. Now (a) applies to u, $v = \mathrm{r}^f_S(u_0)$ and $g_0 = \dot{c}$. □

LEAN `Filling.unipotentChar_eq_of_mem_principalLevel` · `Filling.exists_rat_approx_unipotentChar_eq`

Proof of Theorem D(a). By (G3) over E, with $t = \frac{1}{2}$, write $\gamma = u\,\iota_N(\eta)$ with $u \in \mathcal{U}(T^{\mathrm{rat}}_S(E))$ and $\eta \in \mathrm{U}_\kappa(E)$. By Lemma 3.4(b),

$$\mathrm{pos}_S(c,d;\gamma) = (h_S(c)^{-1}\mathrm{r}^f_S(u)h_S(c)) \cdot \mathrm{inc}_S(\dot{c}^{-1}\eta\,\dot{d}),$$

the first factor in $\mathcal{U}(T^{\mathrm{lat}}_S(\mathbb{A}_{E,f}))$ by Lemma 3.4(c), the second in $\mathcal{H}(T^{\mathrm{lat}}_S(\mathbb{A}_{E,f}))$. The product lies in $K_g(S)$; by Theorem E(a) and (U3) so does the second factor. By (A1), $\dot{c}^{-1}\eta\,\dot{d} \in K^{\mathrm{col}}(S)$. By (F1) and the injectivity of $\mathrm{U}_\kappa(E) \to G_f(E,\kappa)$, the hypothesis of the second part of (U4) holds for $\Gamma = \mathrm{U}_\kappa(E)$, $K = K^{\mathrm{col}}(S)$; hence $c = d$ and $\eta = 1$. So $\gamma = u$, and $\mathrm{pos}_S(c,c;\gamma) \in K_g(S)$ says $\gamma \in \mathcal{U}_{S,c}$. □

LEAN `Filling.eq_and_mem_classUnip_of_besselS`

Proof of Theorem D(b). Let $s = \mathrm{red}_S(k)$ with $k \in K(S)$, $k \in \mathcal{S}(T^{\mathrm{lat}}_S(\mathbb{A}_{E,f}))$. Then $h_S(c)k \in \mathcal{S}(T^{\mathrm{lat}}_S(\mathbb{A}_{E,f}))$, so by (G3) and Lemma 3.4(b), $h_S(c)k = u\,\mathrm{inc}_S(g_0)$ with $u \in \mathcal{U}(T^{\mathrm{lat}}_S(\mathbb{A}_{E,f}))$ and $g_0 \in G_f(E,\kappa)$. Theorem A(b), with $x = u$ and $y = \mathrm{inc}_S(g_0)$, gives $x_0 \in \mathcal{U}(T^{\mathrm{rat}}_S(E))$ with $k' = \mathrm{inc}_S(g_0)^{-1}u^{-1}\mathrm{r}^f_S(x_0)\mathrm{inc}_S(g_0) \in K_g(S)$. By the first part of (U4), $g_0 = \eta\,\dot{d}\,a$ with $\eta \in \mathrm{U}_\kappa(E)$, a class d and $a \in K^{\mathrm{col}}(S)$. Put $\gamma = x_0\,\iota_N(\eta)$; it lies in $\mathcal{S}(T^{\mathrm{rat}}_S(E))$. Using $\mathrm{r}^f_S(x_0) = u\,\mathrm{inc}_S(g_0)\,k'\,\mathrm{inc}_S(g_0)^{-1}$, $h_S(c)^{-1}u\,\mathrm{inc}_S(g_0) = k$ and $\mathrm{inc}_S(g_0)^{-1}\mathrm{inc}_S(\eta)h_S(d) = \mathrm{inc}_S(a)^{-1}$,

$$\mathrm{pos}_S(c,d;\gamma) = h_S(c)^{-1}\mathrm{r}^f_S(x_0)\,\mathrm{inc}_S(\eta)\,h_S(d) = k\,k'\,\mathrm{inc}_S(a)^{-1}.$$

Here $k' \in K_g(S)$ and $\mathrm{inc}_S(a) \in K_g(S)$ by (A1). So the position lies in $K(S)$ and has the reduction $\mathrm{red}_S(k) = s$. □

LEAN `Filling.exists_besselS_mem_termsOver`

Input (N1), unit 50, neatness; proved below. Let E be a CM field with a CM type and at least two infinite places, Ω a finite set, $w_1, \dots, w_\nu$ distinct finite places of E with $(2\#\Omega)^{[E:\mathbb{Q}]} < \prod_j q_{w_j}$, and $K \subseteq K_f(E,\Omega)$ a subgroup of elements that reduce to 1 modulo every w_j. Then $\Gamma_f(E,\Omega) \cap gKg^{-1} = 1$ for every $g \in G_f(E,\Omega)$. This is the statement of the background library. The catalogue of the write-up names Serre [3], appendix, for the method (place not confirmed); by the second reader's verdict Serre's statement, on automorphisms of finite order that are congruent to 1 modulo an integer at least 3, is a different one, and the relation is unresolved. No reference is needed: the statement has the short proof that follows, which is the argument of the formal proof (a trace, its norm, the eigenvalues at the infinite places).

Proof of (N1). Let $\gamma \in \Gamma_f(E,\Omega) \cap gKg^{-1}$ be the image of $\gamma_0 \in \mathrm{U}_\Omega(E)$, and put $t = \mathrm{tr}\,\gamma_0 - \#\Omega \in E$. The matrix $g^{-1}\gamma g$ lies in $K \subseteq K_f(E,\Omega)$ and has the trace of γ, so $t \in E \cap \hat{O}_E = O_E$; and $t = \mathrm{tr}(g^{-1}\gamma g - 1)$ lies in the prime ideal of every w_j, since $g^{-1}\gamma g$ reduces to 1 modulo w_j. As the w_j are distinct, t lies in the product of these prime ideals, so $\prod_j q_{w_j} \le |N_{E/\mathbb{Q}}(t)|$ if $t \neq 0$. At an infinite place τ the

complex matrix $(\gamma_0)_\tau$ is unitary, because the embedding of the CM type commutes with the complex conjugations; so its eigenvalues $\lambda_1, \dots, \lambda_{\#\Omega}$ have absolute value 1, and $|t_\tau| = |\sum_i \lambda_i - \#\Omega| \le 2\#\Omega$. Hence $|N_{E/\mathbb{Q}}(t)| = \prod_\tau |t_\tau|^2 \le (2\#\Omega)^{[E:\mathbb{Q}]}$, and the hypothesis forces $t = 0$. Then $\sum_i \operatorname{Re}\lambda_i = \#\Omega$ with $\operatorname{Re}\lambda_i \le 1$, so every λ_i is 1; a unitary matrix all of whose eigenvalues are 1 is the identity, so $(\gamma_0)_\tau = 1$, and $\gamma_0 = 1$. The second infinite place was not used; the formal proof needs it because it passes through a lemma on forms that are definite at the places other than a fixed one. □

Proposition 6.2 (freeness)**.** *Let E be a stably unramified CM field with a CM type, $\mathfrak{s}$ a shape, $S \in \mathrm{Fill}(E, \mathfrak{s})$, Ω a finite set with $\#\Omega \le k(\mathfrak{s})$, and $i \in \{0, 1\}$. Let $\gamma \in \mathrm{U}_\Omega(E)$ and $g_0 \in G_f(E, \Omega)$ be such that $g_0^{-1}\gamma g_0 \in K_f(E, \Omega)$ and that $g_0^{-1}\gamma g_0$ reduces to 1 modulo every $w \in \mathrm{Ch}_i(S)$. Then $\gamma = 1$.*

Proof. Apply (N1) to the $f = f(E)$ places of $\mathrm{Ch}_i(S)$, all of norm $q_i(S)$ by (F4), and the group K of all elements of $K_f(E, \Omega)$ that reduce to 1 modulo them. Since $[E : \mathbb{Q}] = 2f$, the condition is $(2\#\Omega)^2 < q_i(S)$, and $(2\#\Omega)^2 \le 4k^2 \le 4b^2 < b^{10} \le q_i(S)$ by (F3), (F8). There are at least two infinite places, as $f \ge k \ge 1000$ by (F7); the formal statement of (N1) asks for this. The image of γ lies in $\Gamma_f(E, \Omega) \cap g_0 K g_0^{-1}$, so it is 1, and $\mathrm{U}_\Omega(E) \to G_f(E, \Omega)$ is injective. □

LEAN `Filling.eq_one_of_reduceAt_eq_one`

7 Frames of terms

In this section $S \in \mathrm{Fill}(E, \mathfrak{s})$, and N, b, n abbreviate $N(S)$, $b(S)$, $n(\mathfrak{s})$. Three remarks on frames are used below. For $s, s' \in G(T)$ over any ring with involution: $(ss')\mathfrak{f} = s\,(s'\mathfrak{f})$; for $u \in \mathcal{U}^0(T)$, $(\gamma u)\mathfrak{f} = \gamma\mathfrak{f}$; and $(s^{-1}s')\mathfrak{f} = \mathfrak{f}$ if and only if $s\mathfrak{f} = s'\mathfrak{f}$. Also $s \in \mathcal{S}(T)$ if and only if $(s\mathfrak{f})_{i,a} = \mathfrak{f}_{i,a}$ for all frame indices a and all $i \in I(\mathfrak{s})$ with $\mathrm{lev}(i) \ge a$, which is the definition in Setting 2.1.

LEAN `Filling.frameImage_mul` · `Filling.frameImage_mul_of_mem_besselU0` · `Filling.frameImage_inv_mul_eq_iff` · `Filling.mem_besselS_iff_frameImage`

Lemma 7.1 (a common vector of two frames)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, $\gamma \in G_S(E)$ and $x, y \in E^{\varrho+1}$ with $\mathfrak{f}x = (\gamma\mathfrak{f})y$. Then $\overline{x_\varrho}\,x_\varrho = \overline{y_\varrho}\,y_\varrho$, and $Z_S(\gamma)\,y$ is the vector with the entry $-N(S)\,x_\varrho$ at the index ϱ and 0 elsewhere. Moreover, if $v \in E^{M(\mathfrak{s})}$ has $v_z = 0$ and $v^*\,T_S^{\mathrm{rat}}(E)\,v = 0$, then $v = 0$.*

Proof. For the form h of $T_S^{\mathrm{rat}}(E)$, $h(\mathfrak{f}x, \mathfrak{f}x) = -N\overline{x_\varrho}x_\varrho$, the e_a being isotropic and orthogonal to z; and $h((\gamma\mathfrak{f})y, (\gamma\mathfrak{f})y) = h(\mathfrak{f}y, \mathfrak{f}y)$ by (G6). As $N \ne 0$, the first claim follows. The entry of index a of $Z_S(\gamma)\,y$ is $h(\mathfrak{f}_a, (\gamma\mathfrak{f})y) = h(\mathfrak{f}_a, \mathfrak{f}x)$, which is 0 for $a < \varrho$ and $-Nx_\varrho$ for $a = \varrho$. In the last claim $\sum_{i\in\kappa}|(v_i)_\tau|^2 = 0$ at any infinite place. □

LEAN `Filling.star_mul_last_eq_of_frameImage_eq` · `Filling.frameProducts_mulVec_of_frameImage_eq` · `Filling.eq_zero_of_ratMiddle_form_eq_zero`

Proposition 7.2 (the norm identity)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, $\gamma \in G_S(E)$, $y \in E^{\varrho+1}$, $D \in E$ and $t \in E^{I(\mathfrak{s})}$ such that $Z_S(\gamma)\,y$ is the vector with the entry D at the index ϱ and 0 elsewhere, and $(\gamma\mathfrak{f})y = t$. Then the e^*-coordinates of t vanish, $-N(S)\,t_z = D$, and for every infinite place τ,*

$$N(S)\sum_{i\in\kappa}|(t_{x_i})_\tau|^2 = |D_\tau|^2 - \left(N(S)\,|(y_\varrho)_\tau|\right)^2;$$

if this number is ≤ 0 for some τ, then $t = \mathfrak{f}x$ for some $x \in E^{\varrho+1}$.

Proof. The e_a^*-coordinate of t is $h(e_a, t) = (Z_S(\gamma)y)_a = 0$, and $h(z,t) = -Nt_z$ is the entry of index ϱ, which is D. As t has no e^*-part, $h(t,t) = \sum_i \overline{t_{x_i}} t_{x_i} - N\overline{t_z} t_z$; on the other hand $h(t,t) = h(\mathfrak{f}y, \mathfrak{f}y) = -N\overline{y_\varrho} y_\varrho$ by (G6). Substituting $t_z = -D/N$, multiplying by N and applying the embedding at τ gives the identity. If the left side is ≤ 0 at one place, it is 0 there, so all t_{x_i} vanish and t is a combination of the e_a and z. □

LEAN `Filling.norm_sq_middle_part_eq`

Corollary 7.3. *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, $\gamma \in G_S(E)$ and τ an infinite place of E.*

(a) *$\mathfrak{g}_S(\gamma)_\tau$ is a non-negative real number: $\mathfrak{g}_S(\gamma)_\tau = |\mathfrak{g}_S(\gamma)_\tau|$.*

(b) *If $\mathfrak{g}_S(\gamma) \neq 0$, then $\gamma \in \mathrm{Lv}_{\varrho+1}(S)$.*

(c) $\mathfrak{g}^{\mathbb{R}}(Z(\mathrm{r}_S^\infty(\gamma)_\tau)) = \left(\prod_{a \le \varrho} \mathrm{fs}_S(\tau, a)\right)^2 \cdot |\mathfrak{g}_S(\gamma)_\tau|$.

Proof. (a) Let $Z = Z_S(\gamma)$ and let y be the last column of the adjugate of Z, so that Zy has the entry $\det Z$ at ϱ and 0 elsewhere, and $y_\varrho = \mathrm{D}_\varrho(Z)$. Proposition 7.2 with $D = \det Z$ shows that $\mathfrak{g}_S(\gamma)_\tau = |\det Z_\tau|^2 - N^2 |\mathrm{D}_\varrho(Z)_\tau|^2$ is N times a sum of squares. (b) Normal form from $\varrho + 1$ is an empty condition. If $\det Z = 0$, then $\mathfrak{g}_S(\gamma)_\tau \le 0$, hence $= 0$ by (a), against the hypothesis; so $\mathrm{D}_{\varrho+1}(Z) \neq 0$. (c) By Lemma 3.2(b) the determinant of $Z(\mathrm{r}_S^\infty(\gamma)_\tau)$ is $\prod_{a \le \varrho} \mathrm{fs}_S(\tau, a) \cdot \det Z_\tau$ and its leading minor of order ϱ is $\prod_{a < \varrho} \mathrm{fs}_S(\tau, a) \cdot \mathrm{D}_\varrho(Z)_\tau$; and $\mathrm{fs}_S(\tau, \varrho) = 1/N$. With (a) this gives the formula. □

LEAN `Filling.map_termDisc_eq_norm` · `Filling.hasLevel_last` · `Filling.gramDiscReal_realFrameGram_ratToInf`

Inputs (the real place), unit 132. For $x, y \in G_1(\mathfrak{s})$, frame indices a, b, and $t \in G_1(\mathfrak{s})$: (R1) $|Z(x)_{ab}| \le \|y^{-1}\mathfrak{f}_a\| \cdot \|(x^{-1}y)^{-1}\mathfrak{f}_b\|$; (R2) $\mathrm{bs}(ty) = \mathrm{bs}(y)$ if $t \in \mathcal{S}(T^{\mathrm{rat}}(\mathfrak{s}; 1))$; (R3) $(ty)^{-1}\mathfrak{f}_a = y^{-1}\mathfrak{f}_a$ if t lies in the group generated by $\mathcal{U}^0(T^{\mathrm{rat}}(\mathfrak{s}; 1))$ and $\mathcal{H}(T^{\mathrm{rat}}(\mathfrak{s}; 1))$.

Lemma 7.4 (near terms and the archimedean coordinates)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, $\gamma, u, u' \in G_S(E)$ and τ an infinite place of E.*

(a) *If $u \in \mathcal{U}^0(T_S^{\mathrm{rat}}(E))$, then $\mathrm{r}_S^\infty(u)_\tau \in \mathcal{U}^0(T^{\mathrm{rat}}(\mathfrak{s}; 1))$.*

(b) *Let $y, t \in G_\infty(E, \mathfrak{s})$ with $t_{\tau'} \in \mathcal{U}^0(T^{\mathrm{rat}}(\mathfrak{s}; 1))$ for every infinite place τ'. Then $ty \in \mathrm{BxP}(S)$ if and only if $y \in \mathrm{BxP}(S)$.*

(c) *If $\gamma \in \mathrm{Near}(S)$, $u \in \mathcal{U}^0(T_S^{\mathrm{rat}}(E))$ and $u' \in \mathcal{U}^0(T_S^{\mathrm{rat}}(E))$, then $u\gamma u' \in \mathrm{Near}(S)$.*

(d) *For a natural number j: if $\gamma \in \mathrm{NF}_j$, then $\mathrm{r}_S^\infty(\gamma)_\tau \in \mathrm{NF}_j$.*

Proof. (a) Conjugation by the diagonal matrix $\mathrm{Sc}_{S,\tau}$ and the embedding at τ preserve the entries equal to 0 or 1 that define $\mathcal{U}^0(\cdot)$. (b) By (R2), (R3), since $\mathcal{U}^0(T^{\mathrm{rat}}(\mathfrak{s}; 1)) \subseteq \mathcal{S}(T^{\mathrm{rat}}(\mathfrak{s}; 1))$. (c) If y and $\mathrm{r}_S^\infty(\gamma)^{-1}y$ lie in $\mathrm{BxP}(S)$, then so do $\mathrm{r}_S^\infty(u)y$ and $\mathrm{r}_S^\infty(u\gamma u')^{-1}\mathrm{r}_S^\infty(u)y = \mathrm{r}_S^\infty(u')^{-1}\mathrm{r}_S^\infty(\gamma)^{-1}y$, by (a) and (b). (d) Let c be the constant of the normal form; then $|c_\tau|^2 = 1$. For a frame index $a \ge j$ and x, y with $\mathfrak{f}x = (\gamma\mathfrak{f})y$, put $d_b = \mathrm{sc}_{S,\tau}(\mathfrak{f}_a)/\mathrm{sc}_{S,\tau}(\mathfrak{f}_b)$ and $x'_b = d_b(x_b)_\tau$, $y'_b = d_b(y_b)_\tau$. Applying the embedding and the diagonal matrix $\mathrm{sc}_{S,\tau}(\mathfrak{f}_a)\,\mathrm{Sc}_{S,\tau}^{-1}$ to the equation gives $\mathfrak{f}x' = (\mathrm{r}_S^\infty(\gamma)_\tau\mathfrak{f})y'$; the supports are unchanged, and $x'_a = c_\tau$, $y'_a = 1$. □

LEAN `Filling.ratToInf_mem_besselU0` · `Filling.mul_mem_boxedPoints_iff` · `Filling.IsNear.mul_of_mem_besselU0` · `IsNormalForm.ratToInf`

Lemma 7.5 (terms in the lattice basis)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$, $c, c' \in \mathrm{Cl}(S)$, $s \in \mathsf{G}(S)$ and $\gamma \in G_S(E)$.*

(a) $\mathrm{C}_S(c)^*\ J(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))\ \mathrm{C}_S(c) = J(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))$.

(b) $\mathrm{pos}_S(c, c'; \gamma)\, \mathfrak{f} = \mathrm{C}_S(c) \cdot (\gamma \mathfrak{f})_{\mathbb{A}_f}$, *and* $Z_{T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})}(\mathrm{pos}_S(c, c'; \gamma)) = (Z_S(\gamma))_{\mathbb{A}_f}$.

(c) *If $\gamma \in \mathrm{Tm}_S(c, s, c')$, then $\mathrm{pos}_S(c, c'; \gamma)$ has entries in $\hat{O}_E$, and for all frame indices a, b the entry $Z_S(\gamma)_{ab}$ is an algebraic integer.*

Proof. (a) By Lemma 2.3(a) and (F2), $\Lambda(S)^*\, J(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))\, \Lambda(S) = J(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, and $\iota_N(\dot{c})$ is an isometry of $T_S^{\mathrm{rat}}(\mathbb{A}_{E,f})$; so $\mathrm{B}_S(c)^* J(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))\mathrm{B}_S(c) = J(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$, which is (a) for the inverse matrix. (b) By Lemma 3.4(c), $\mathrm{pos}_S(c, c'; \gamma) = \mathrm{C}_S(c)\, \gamma\, \mathrm{B}_S(c')$, and $\mathrm{B}_S(c')$ fixes the frame vectors: $\iota_N(\dot{c}')$ acts on the x_i only and $\Lambda(S)$ fixes the e_a and z. This is the first formula. By (G4) and (a),

$$\begin{aligned} Z_{T_S^{\mathrm{lat}}(\mathbb{A}_{E,f})}(\mathrm{pos}_S(c, c'; \gamma)) &= \mathfrak{f}^*\, J(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))\, \mathrm{C}_S(c)\, \gamma \mathfrak{f} \\ &= (\mathrm{B}_S(c)\mathfrak{f})^*\, J(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))\, \gamma \mathfrak{f} = \mathfrak{f}^* J(T_S^{\mathrm{rat}}(\mathbb{A}_{E,f}))\gamma \mathfrak{f}. \end{aligned}$$

(c) The position lies in $K(S)$. By (b) the matrix $(Z_S(\gamma))_{\mathbb{A}_f}$ is a block of the product of the integral matrices $J(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))$ and $\mathrm{pos}_S(c, c'; \gamma)$; an element of E that is integral at all finite places is an algebraic integer. □

LEAN `Filling.classCoord_conj_splitGram` · `Filling.frameImage_termPosition` · `Filling.frameGram_termPosition` · `Filling.termsOver.isIntMatrix_termPosition` · `Filling.isIntegral_frameProducts`

Proof of Theorem D(c). The element $\delta = \gamma^{-1} u$ fixes the frame, so it lies in $\mathcal{S}(T_S^{\mathrm{rat}}(E))$. By Lemma 3.4(d) it is a term over $(c', s^{-1}s, d) = (c', 1, d)$, that is, $\mathrm{pos}_S(c', d; \delta)$ lies in $K_g(S)$. Theorem D(a) gives $c' = d$ and $\delta \in \mathcal{U}_{S,c'}$; as δ fixes the frame, $\delta \in \mathcal{U}^0_{S,c'}$. □

LEAN `Filling.termsOver.eq_and_mem_classUnip₀`

Lemma 7.6 (sizes)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$ and e a natural number.*

(a) *If $e \le 10^5\, n(\mathfrak{s})^9\, f(E)$, then $b(S)^e \le \mathrm{tl}(S)$.*

(b) $\mathrm{tl}(S)^4 = b(S)^{k(\mathfrak{s})\, f(E)}$.

(c) $2 \le g(S)$; $2 \le \mathrm{tl}(S)$; $1000 \le b(S)$; $0 \le \mathsf{d}_1(S)$; $0 \le \mathsf{d}(S)$; $0 < N(S)$; $0 < \nu(S)$; *and* $\overline{\mathcal{S}(T_S^{\mathrm{lat}}(\mathbb{A}_{E,f}))}^{S}$ *is not empty. (In the formal text: a statement p holds as soon as it follows from these facts together with $2 \le b(S)$, $0 < b(S)$ and $1 \le b(S)$.)*

Proof. (a) $\mathrm{tl}(S) = b^{kf/4}$ with $b \ge 1000 > 1$, and $e \le 10^5 n^9 f \le 1000(2n)^9 f/4 \le kf/4$ by (F7). (b) is the definition. (c) g is a product of two primes; $\mathrm{tl}(S) \ge b \ge 2$ by (a) with $e = 1$; $\mathsf{d}(S)$ is a square divided by the product of the positive numbers $\deg(S)$ and $\mathrm{mass}(E, r)$ (the mass is positive: background, unit 99); N is a prime; $\nu(S) > 0$ by Lemma 3.1; and the reduced image is a group. □

LEAN `Filling.pow_le_tailScale` · `Filling.tailScale_pow_four` · `Filling.of_size_bounds`

Proposition 7.7 (frame products of near terms are small)**.** *Let $S \in \mathrm{Fill}(E, \mathfrak{s})$ be admissible filling data, $\gamma \in G_S(E)$ with $\gamma \in \mathrm{Near}(S)$, τ an infinite place of E, $a, b \le \varrho$ frame indices and $l \le \varrho + 1$. Then, with $n = n(\mathfrak{s})$,*

$$|(Z_S(\gamma)_{ab})_\tau| \le b(S)^{5n^2} \qquad \text{and} \qquad |\mathrm{D}_l(Z_S(\gamma))_\tau|^2 \le b(S)^{11n^3}.$$

Proof. Let $y \in \mathrm{BxP}(S)$ with $y' = \mathrm{r}_S^\infty(\gamma)^{-1} y \in \mathrm{BxP}(S)$. By (R1) for $x = \mathrm{r}_S^\infty(\gamma)_\tau$, $|Z(\mathrm{r}_S^\infty(\gamma)_\tau)_{ab}| \le \|y_\tau^{-1}\mathfrak{f}_a\| \, \|y_\tau'^{-1}\mathfrak{f}_b\| \le \mathrm{bx}(S)^2 = b^{4n^2}$. By Lemma 3.2(b) the left side is $|\kappa_\tau(S)|^{2\varrho-a-b} N^{-1} |(Z_S(\gamma)_{ab})_\tau|$, and $|\kappa_\tau(S)| \ge 1$, $N \le b^{60n}$ by (A2), (A3). So $|(Z_S(\gamma)_{ab})_\tau| \le b^{60n+4n^2} \le b^{5n^2}$, since $n \ge 10^5$ by (F7). A determinant of size l with entries of absolute value at most $B = b^{5n^2}$ is at most $l!\, B^l \le (lB)^l$ in absolute value, and $l \le n \le b$ by (F8); so its square is at most $(b^{1+5n^2})^{2n} = b^{2n+10n^3} \le b^{11n^3}$. □

8 Notes on the formal text

Arguments as the census reads them. The census of the artifact reads the arguments of a declaration from its text, without running Lean, and for some declarations of this note the reading is evidently not Lean's signature: a variable of the file is counted because the declaration binds a variable of the same name, or because a name such as that of $b(S)$ contains its letter; or the reading stops at a definition inside a statement. The reader of the unit recorded these cases, with Lean's presumable signature and the evidence for it; nothing was compiled. The definitions concerned are written here with Lean's arguments: the reduction red_S and the maps $\mathrm{r}_S^{\mathbb{A}}$, a_S^∞, a_S^f (the census reads the source of the homomorphism as an argument); the scales $\mathrm{sc}_{S,\tau}(i)$, the numbers $\mathrm{fs}(S)$, $\nu(S)$, $\deg(S)$; the sets $\mathrm{Tm}_S(c,s,c')$, $\mathrm{Tm}_S^{\mathrm{lk}}(\Lambda)$, $\mathrm{FBox}(\rho)$ and the properties $\omega \in \mathrm{BP}(S,c)$, $\Xi \in \mathrm{Stab}(S)$, $\gamma \in \mathrm{NF}_j$, S is admissible (a bound variable is counted); the notions $\mathrm{J}(\mu, W; \gamma)$, $\mathrm{Sch}(W) \le D$, $\mathrm{SchB}(W, \mathrm{rep}; B, D)$, $\mathrm{CP}(b, f, \mathrm{rep}, W)$, $\mathrm{BSys}(\mathfrak{s}, b, f)$ (variables of the file are counted, for a Bessel system the components I, W, deg of the record itself); the matrix $\mathrm{m}_H(V)$ (the hypothesis $LH = 1$ is missed). The Bessel function $W_S^\sigma(y)_i$, the kernel $\mathcal{W}_S^\sigma(\gamma; y)$, the amplitudes and the amplitude sum take the side as an ambient argument in Lean, which the census does not list; the notation shows it. The notations $\mathrm{B}_S(c)$, $\mathrm{Fix}_{S,w}(d)$, $\mathrm{Fix}_S(\Sigma, d)$ show the data S, which Lean takes implicitly. For theorems the same happens in the statements of Propositions 2.11, 5.2, 7.2, 7.7, of Lemmas 3.2(b), 3.3, 5.1, 7.4(b), 7.6 and of Corollary 4.3; in each case the statement here has Lean's arguments, as far as the text shows them, and the account of the census's extra arguments points to the words of the statement that name the bound variable. In Proposition 4.4(a) the census misses the sequence p, which the statement uses. For Proposition 7.7 the census reads the proof of the first bound as part of its statement, and lists as an argument a hypothesis (γ is a term) that the statement does not have; the reader gave the argument in a note, and the proof here follows the Lean text.

Where the formal text differs from the statements above. (1) Theorem C(b) is, in the formal text, a sum over all subspaces of a term that is 0 unless the dimension condition holds, in $[0, \infty]$. (2) The conclusion of Proposition 2.10 is stated there for the function $x \mapsto \max(\mathrm{Re}\, F(x), 0)$ with values in $[0, \infty]$; it equals F by the first assertion. Its hypothesis on the common entry of index i is used only for $i = n$. (3) Lemma 3.3(b) gives the cutoff in both forms, as a sum over K and as an integral for the counting measure of Γ. (4) The cutoff $\beta_{S,c}$ is defined by two choices; the second is a choice among the functions ω with $\omega \in \mathrm{BP}(S,c)$ and is arbitrary when there is none. Nothing in this note depends on it; Note B proves that such functions exist under the standing hypotheses when E is stably unramified. (5) The record

of filling data lists some consequences of its own conditions: $1 \le b$ beside $1000 \le b$, and $1000(2\varrho+2) \le k$ beside $1000(2\varrho+2)^9 \le k$. (6) The comment of the formal text on $c_*(S)$ gives the second formula of the remark after Definition 2.22; the definition is the first. (7) Lemma 7.6(c) is stated in the formal text as a rule: a proposition holds if it follows from the listed facts. (8) In Lemma 3.6(a) and in the facts that $T_S^{\mathrm{rat}}(E)$ and $T_S^{\mathrm{lat}}(F)$ are hermitian and invertible, that $\frac{1}{2} \in \mathbb{A}_{E,f}$ has trace 1, that $\mathrm{Cl}(S)$ is finite and $G_S(E)$ countable, the formal text has instances without names; they are not in the concordance. (9) Theorem B(b) is the precise form of "the link is Lagrangian"; the dimension of the link is computed in Note B. (10) The Inputs (U1), (La2), (La4) and (M1) are stated here in the special cases that are used: (U1) combines an induction principle over the floors with the description of the elements of one floor; (La4) is the case of the formal lemma in which its additional block is absent.

What this note takes for granted. From the background library: the groups of Setting 2.1 and the Inputs (G1)–(G6), (E1), (L1), (L2), (U1)–(U4) (units 1, 29, 112, 119, 120); adeles, the standard characters and cutoffs (Ad1)–(Ad4) (units 114, 122, 123); lattices and indices (La1)–(La4) (units 57, 120); Minkowski's second theorem, Gram–Schmidt, the first minimum and a packing bound (M1)–(M4) (units 114, 120, 121); the positivity of the mass (unit 99); and neatness (N1) (unit 50), which is not taken for granted any more: since the revision after the referee's report a proof follows its statement. From the notes on the real place (unit 132): (R1)–(R3). The notions of Bessel function and of the measure $\mu_{\mathcal{U}\backslash G}$ are background (units 117, 118).

How this note was written. From the dossier of the unit: the texts of the members of the nine files treated here and their structured proofs. I read the nine Lean files completely, and compared every statement of this note with the Lean statement, argument by argument; for the statements that contain a local definition I read the full Lean text and not the census's span. For Proposition 7.7, which has no structured proof, I read the proof in the Lean text. The proofs follow the formal ones in their structure. Written out here where the formal text calls a decision procedure or a simplifier: the verification that the Eichler map of Proposition 2.11 is unitriangular; the inverse of the lattice form in Lemma 2.3; the bookkeeping of Lemma 3.9; the exponents of Proposition 7.7 and of Proposition 6.2. In the proof of Theorem C(a) I use that the index in Jacobi's identity is 1, so that the discriminants of a subspace and of its orthogonal complement agree; the formal text uses only that it is at least 1. Identities between explicit matrices that the formal text checks entry by entry (the image of a rational Heisenberg element, the matrix of the lattice basis and its inverse) are stated and not recomputed. Of the Inputs I read the Lean statements of (La2), (La4), (M1), (M4), (N1), (L1), (R1)–(R3), (G3) and (U3) and the dossier's readings of the others; I did not open their proofs. The references are those of the second reader's verdicts and of the catalogue of the write-up; I did not open the cited works. The program check of the unit's dossier covered 1371 leaf steps of 179 proofs.

Appendix A. Concordance with the Lean artifact

The formal names of the objects are these. The fields `S.N`, `S.levelPrime i`, `S.piBar`, `S.ϖ`, `S.b`, `S.chosenPlaces i`, `S.columnLevel`, `S.besselSys v` are $N(S)$, $q_i(S)$, $\bar{\pi}(S)$, $\varpi(S)$, $b(S)$, $\mathrm{Ch}_i(S)$, $K^{\mathrm{col}}(S)$, $\mathfrak{B}_\tau(S)$; the Lean variable `v` for an infinite place is τ and `𝔓 v x` is x_τ; `besselU`, `besselU0`, `besselH`, `besselS`, `GT l` are $\mathcal{U}(T)$, $\mathcal{U}^0(T)$, $\mathcal{H}(T)$, $\mathcal{S}(T)$, $\mathcal{H}_l(T)$; `frameGram`, `realFrameGram`, `leadingMinor`, `simpleRootSum`, `frameImage` are $Z_T(\gamma)$, $Z(y)$, $\mathrm{D}_l(Z)$, $\mathrm{sd}(u)$, $\gamma\mathfrak{f}$; `genIndex` is $[\cdot]$; `toBesselH` is ι_N; a set `T` of rational elements is Ξ, the subspace `T` of Siegel's lemma is V, and the finite index sets `τ`, `σ` are Ω. Four statements as the artifact has them:

Notation

E, O_E, $\overline{x}$ a CM field, its integers, complex conjugation or the involution of a ring

τ, x_τ an infinite place of E; the image of $x \in E$ under the embedding of the CM type

w, $\overline{w}$, $\mathbb{F}_w$, q_w a finite place, its conjugate, the residue field, its number of elements

$\mathbb{A}_E$, $\mathbb{A}_{E,f}$, $\hat{O}_E$ adeles, finite adeles, integral finite adeles

$f(E)$, d_E, rd_E, $\mathrm{vol}(\hat{O}_E)$ number of infinite places, discriminant, root discriminant, $2^f/\sqrt{|d_E|}$

ψ_f, ψ_E, $\mathbf{e}$ standard additive characters; $\mathbf{e}(c) = e^{c-\overline{c}}$

π, ε_w, ϵ the number π; the idempotent of $\hat{O}_E$ at w; a truth value, or the factor of Definition 2.14

$[a]$ generalized index of a unit a

$\mathfrak{s} = (\varrho, \kappa, k_0)$ a shape; $k(\mathfrak{s})$, $n(\mathfrak{s})$, $r(\mathfrak{s})$, $M(\mathfrak{s})$, $I(\mathfrak{s})$: Setting 2.1

e_a, x_i, z, e_a^*; $\mathfrak{f}_a$, $\mathfrak{f}$ the basis; the frame

lev, fl level and floor of a basis vector

R, R', F, A, C, K_0 rings; K_0 a field

T, T', $T^{\mathrm{rat}}(\mathfrak{s}; N)$, $J(T)$, h_T, h forms, the diagonal form, the split Gram matrix, the hermitian form

$G(T)$, $G_1(\mathfrak{s})$, $G_\infty(E, \mathfrak{s})$ unitary groups; the product over the infinite places

$\mathcal{U}(T)$, $\mathcal{U}^0(T)$, $\mathcal{H}(T)$, $\mathcal{H}_l(T)$, $\mathcal{S}(T)$ unipotent group, its frame-fixing part, the groups $\mathcal{H}$, the Bessel subgroup

$Z_T(\gamma)$, $Z(y)$, Z, $\mathrm{D}_l(Z)$ frame Gram matrices; leading principal minors

$\mathrm{sd}(s)$, $w_l(p)$, ι_N, $\nu_l(v,\beta)$ sum of the superdiagonal frame entries, Weyl element, embedding of U_κ, Heisenberg element

M^*, M^{t}, $(M)_{\mathbb{A}_f}$ conjugate transpose, transpose, the same matrix over $\mathbb{A}_{E,f}$

$T^{\mathrm{lat}}(\mathfrak{s};N)$, $\Lambda^\circ(\mathfrak{s};p)$, $\Lambda(\mathfrak{s};p)$ lattice form, base change, lattice basis: Definition 2.2

$\mathfrak{g}(N;Z)$, $\mathfrak{g}^{\mathbb{R}}(Z)$ frame discriminants: Definitions 2.4, 2.12

$[\mathfrak{f} \mid \gamma\mathfrak{f}]$, $[\mathfrak{e} \mid \gamma\mathfrak{e}]$, $\mathrm{L}(\gamma)$, $\mathrm{link}(\gamma)$ frame pairs, link matrix, link: Definition 2.5

X, t_{mid} the span of the e_a; middle part of a vector

$\mathrm{dp}_k(r)$, $\Lambda^{\mathbb{C}}_K(i;p)$, $\Lambda_K(i;p)$ damped power, head weights: Definition 2.6

$\mathrm{Sieve}(u,\iota,n,J,\psi,En,\Lambda,\beta)$ sieve system: Definition 2.7; U, ξ, Ω, $u_{\mathbb{C}}$

$c_G(\mathfrak{s})$, $c_{\mathrm{band}}(\mathfrak{s})$, $\mathrm{bs}(y)$, $y \in \mathrm{Cut}(b)$, $\mathrm{FBox}(\rho)$, $\mathrm{cm}(y;\deg,\rho,d)$ Definition 2.12

$\mathrm{J}(\mu,W;\gamma)$, $\mathrm{Sch}(W) \le D$, $\mathrm{SchB}(W,\mathrm{rep};B,D)$, $\mathrm{J}^\circ(y;W,p)$, $\mathrm{BL}(b,W,\deg,J)$ Definition 2.13; φ, V_w, X, B, D

σ, full, cut; $\mathrm{CP}(b,f,\mathrm{rep},W)$, $\mathrm{BSys}(\mathfrak{s},b,f)$ sides; cut pairs, Bessel systems: Definition 2.14; m, ϵ, P, $\mathfrak{B}$, Φ, g

$\mu_{\mathcal{U}\backslash G}$, vol the measure for $\mathcal{U}\backslash G_1$; volumes

$S \in \mathrm{Fill}(E,\mathfrak{s})$ filling data: Definition 2.15; $N(S)$, $q_i(S)$, $\bar{\pi}(S)$, $\varpi(S)$, $b(S)$, $\mathrm{Ch}_i(S)$, $K^{\mathrm{col}}(S)$, $\mathfrak{B}_\tau(S)$

$I_\tau(S)$, $W^\sigma_{S,\tau}$, $\deg_\tau(S)$, $\mathrm{rep}_{S,\tau}$ the components of the Bessel system at τ

$G_f(E,\kappa)$, $K_f(E,\kappa)$, $\Gamma_f(E,\kappa)$, U_κ finite adelic unitary group, its integral subgroup, rational points

$g(S)$, $T^{\mathrm{rat}}_S(R)$, $T^{\mathrm{lat}}_S(R)$, $G_S(R)$, G^{lat}_S, $\mathsf{G}(S)$, $\mathrm{Bc}(S)$, $\mathrm{Cl}(S)$, $\dot{c}$, $Z_S(\gamma)$, $\mathfrak{g}_S(\gamma)$ Definition 2.16

$K(S)$, red_S, $K_g(S)$, $\overline{A}^S$, $\hat{g}(S)$ Definition 2.17

$\kappa_\tau(S)$, $\mathrm{sc}_{S,\tau}(i)$, $\mathrm{Sc}_{S,\tau}$, $\mathrm{fs}_S(\tau,a)$, $\mathrm{fs}(S)$ Definition 2.18

$\Lambda(S)$, lb_S, $\mathrm{r}^{\mathbb{A}}_S$, a^∞_S, a^f_S, r^∞_S, r^f_S, inc_S, $h_S(c)$, ψ_S, $\psi^{\mathcal{U}}_S(u)$ Definition 2.19

$\mathrm{pos}_S(c,c';\gamma)$, $\mathrm{Tm}_S(c,s,c')$, $\mathcal{U}_{S,c}$, $\mathcal{U}^0_{S,c}$, $s \in \mathrm{Agr}(S)$, $\Xi \in \mathrm{Stab}(S)$, $\mathrm{Tm}^{\mathrm{lk}}_S(\Lambda)$ Definition 2.20

$W^\sigma_S(y)_i$, $\mathcal{W}^\sigma_S(\gamma;y)$, $\mathrm{bx}(S)$, $\omega \in \mathrm{BP}(S,c)$, $\beta_{S,c}$, $a^\sigma_S(c,c';\gamma)$, $|a|^\sigma_S(c,c';\gamma)$, $A^\sigma_S(\Xi;c,s,c')$ Definition 2.21; α, β^0
